DOI: 10.1039/b901607d

The combination of a [zinc(II)–4,4′-bpy] coordination moiety with, respectively, formate, acetate and propionate ligands leads to the formation of the compounds  $\{[Zn_3(4,4′-bpy)_{3.5}(\mu-O_2CH)_4(H_2O)_2](ClO_4)_2(H_2O)_2\}_n$  (**1**),  $\{[Zn_3(4,4′-bpy)_3(\mu-O_2CCH_3)_4(H_2O)_2](PF_6)_2(H_2O)_2\}_n$  (**2**) and  $\{[Zn_3(4,4′-bpy)_4(\mu-O_2CCH_2CH_3)_4](ClO_4)_2(4,4′-bpy)_2(H_2O)_4\}_n$  (**3**). The molecular structures determined by single-crystal X-ray diffraction data reveal significant changes, which are apparently due to the sole different steric hindrance between a H atom (formate, compound **1**), a methyl group (acetate, compound **2**) and an ethyl group (propionate, compound **3**). The three coordination materials have been fully characterized and their thermal decomposition behavior has been investigated. The 3D (**1**), 1D (**2**) and 2D (**3**) networks exhibit voids that contain the counter-ions and guest molecules as well, namely water for compounds **1** and **2**, and water/4,4′-bpy for compound **3**.

## Introduction

During the past 15 years, the field of coordination polymer research has become an extremely prolific area of chemistry.<sup>1–3</sup> In this context, a number of crystal engineering investigations are aimed at trying to understand how a variety of factors, like the metal ions, reaction conditions and secondary co-ligands,<sup>4</sup> may affect the molecular structures and/or properties of coordination polymers.<sup>5–7</sup>

Coordination polymer networks, also known as metal–organic frameworks (MOFs),<sup>8</sup> are based upon self-assembly between metal ions (typically transition-metal ions) characterized by inherent preferences in coordination geometry and at least dinucleating ligands.<sup>9</sup> (Poly)carboxylato ligands are commonly being used to generate MOFs of diverse topologies.<sup>10</sup> Moreover, the combination of metal–carboxylato building blocks with a secondary co-ligand (usually a dinucleating N-donor ligand, such as 4,4′-bipyridine, **4,4′-bpy**) allows a considerable enhancement of the structural diversity of the coordination materials.<sup>11</sup> Actually, numerous remarkable coordination

networks built from **4,4′-bpy** and carboxylato ligands have been reported in the literature,<sup>12–19</sup> for which the nature of the carboxylato molecule plays an important structural role.<sup>20–23</sup>

In the present study, the effect of the steric hindrance of different carboxylato ligands (formate, acetate and propionate ligands) on the solid-state structure of the corresponding coordination materials has been investigated. Thus, three multicomponent polymeric networks have been synthesized from zinc(II) ions, **4,4′-bpy** and a carboxylato ligand, whose single-crystal X-ray structures reveal a significant influence of a hydrogen (formate), a methyl (acetate) and an ethyl (propionate) group on the assembly of the coordination framework. The compounds  $\{[Zn_3(4,4′-bpy)_{3.5}(\mu-O_2CH)_4(H_2O)_2](ClO_4)_2(H_2O)_2\}_n$  (**1**),  $\{[Zn_3(4,4′-bpy)_3(\mu-O_2CCH_3)_4(H_2O)_2](PF_6)_2(H_2O)_2\}_n$  (**2**) and  $\{[Zn_3(4,4′-bpy)_4(\mu-O_2CCH_2CH_3)_4](ClO_4)_2(4,4′-bpy)_2(H_2O)_4\}_n$  (**3**) have been synthesized and characterized and their thermal stability has been examined.

## Results and discussion

### Crystal structure of $\{[Zn_3(4,4′-bpy)_{3.5}(\mu-O_2CH)_4(H_2O)_2](ClO_4)_2(H_2O)_2\}_n$ (**1**)

The 3D molecular structure of compound **1** exhibits four different types of zinc(II) ions, each with octahedral  $N_2O_4$  coordination environments (Fig. 1). The basal plane of the octahedron around Zn1 is formed by four oxygen atoms belonging to three formate ligands. The axial positions are occupied by two pyridine N-donors from two different (bridging) **4,4′-bpy** moieties (for the atom Zn3, the **4,4′-bpy** units act as monodentate ligands; see green **4,4′-bpy** ligands in Fig. 2). The formate ligand [O2, O12] acts as a bridging  $\mu-O, O'$  ligand, connecting Zn1 to Zn3 (Fig. 1). The formate ligand [O3, O8] functions as a  $\mu_3-O, O, O'$  ligand, bridging Zn1 and Zn3 and connecting the {Zn1, O3, Zn3} unit to an adjacent Zn4 ion

(through the oxygen atom O8). The third formate ligand [O1, O9] is chelating the atom Zn1 (Fig. 1) and is coordinated as well (through the atom O9) to a neighbouring Zn2 ion, thus acting as a  $\mu$ -O,O',O' ligand.

The Zn–O and Zn–N bond distances are in normal ranges for this type of chromophore (Table 1).<sup>21,24</sup> The coordination angles, varying from 53.31(9) to 122.98(11)° (Table 1), reflect a strong distortion of the octahedron which is principally due to the very small bite angle of the chelating formate ligand.

The basal plane of the octahedron around Zn2 is constituted of two oxygen atoms (O9 and O9c) from two  $\mu$ -O,O',O'-formate ligands and two water oxygen atoms (O4 and O5). Zn2 lies on a two-fold axis and is coordinated by two different 4,4'-bpy moieties (N2a and N2b) at the axial positions. The Zn–O and

<sup>a</sup> Symmetry operations:  $a = 1 - x, y, 1/2 - z$ ;  $b = 1 - x, y, 3/2 - z$ ;  $c = 1 - x, -y, 1 - z$ ;  $d = x, -y, -1/2 + z$ ;  $e = 3/2 - x, 1/2 + y, 3/2 - z$ .

Zn–N bond distances can be considered as normal for this type of coordination environment (Table 1).<sup>25</sup> The basal angles ranging from 82.75(9) to 97.25(9)° indicate a distortion of the octahedral geometry, attributed to constraints induced by the bridging of the  $\mu$ -O,O',O'-formate ligands to Zn1.

The N<sub>2</sub>O<sub>4</sub> coordination environment around the Zn3 ion, which lies on an inversion centre, is an almost perfect octahedron (the basal angles vary from 87.99(11) to 92.01(11); Table 1), with four in-plane oxygen atoms belonging to distinct formate ligands (O3, O12, O3d and O12d; Fig. 1). The axial positions are occupied by the nitrogen atoms N5 and N5d from two 4,4'-bpy ligands. The Zn–O and Zn–N bond lengths are in common ranges.<sup>21</sup>

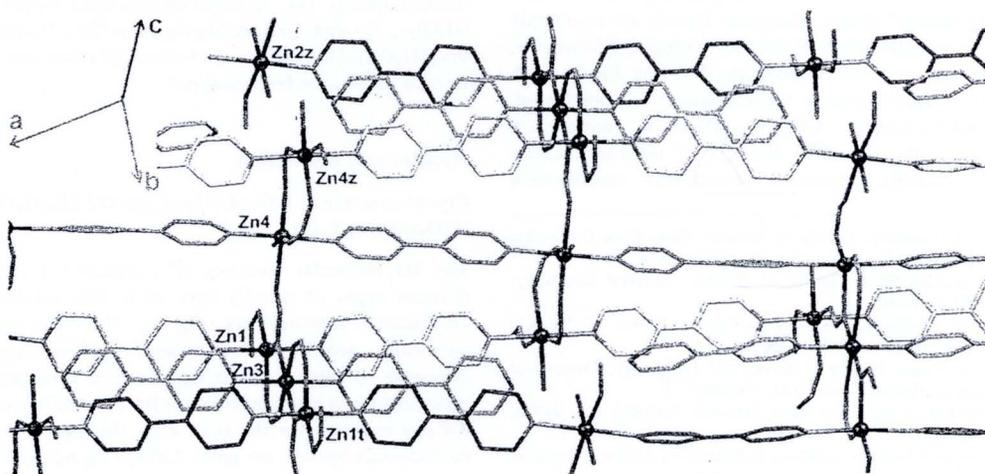

Fig. 2 3D coordination network of Zn<sup>II</sup>, 4,4'-bipyridine and formate. The 4,4'-bpy ligands involved in the formation of trinuclear zinc units are shown in blue, green and orange for comparison with compounds **2** and **3**. The 4,4'-bpy ligands generating a 1D chain are depicted in red. Symmetry operations:  $t = 1/2 - x, -1/2 + y, 1/2 - z$ ;  $z = 1 - x, y, 3/2 - z$ .

The distorted octahedral geometry around Zn4 (the basal angles range from 77.31(13) to 114.80(18)°) is most likely due to the bite angle of the  $\mu$ -O,O'-formate ligands (oxygen atoms O6 and O7), connecting Zn4 to a symmetry-related Zn4 ion (see Fig. 2). The Zn–O and Zn–N bond distances are in normal ranges.<sup>25</sup>

The self-assembly between these bridging N- and O-ligands and zinc(II) ions gives rise to a remarkable 3D architecture (Fig. 2). The metal–organic framework is formed from trinuclear [Zn1, Zn3, Zn1] clusters which are connected through two 4,4'-bpy ligands (yellow and blue 4,4'-bpy ligands in Fig. 2) to the Zn2 and Zn4 ions, generating 1D, triple-stranded infinite chains. These chains showing  $\pi$ - $\pi$  interactions between three 4,4'-bpy units (with centroid-to-centroid distances ranging from 3.491(4) to 3.839(4) Å) are connected to each other *via* a different infinite single chain exhibiting the sequence {Zn1, Zn4, Zn4, Zn1, Zn2, ...} (chain built from the orange 4,4'-bpy ligands in Fig. 2). This spatial arrangement produces a unique heptanuclear coordination metallacycle (Fig. 3).

The organization of these heptanuclear motifs in the crystal lattice gives rise to the formation of channels which are filled by disordered perchlorates and water molecules (Fig. 4).

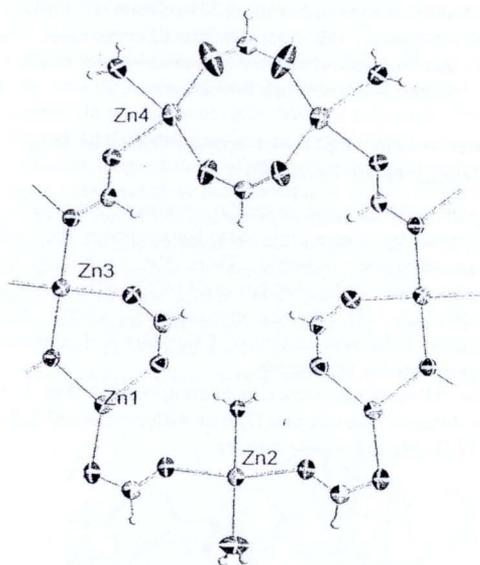

Fig. 3 Heptanuclear building unit constituting the channel walls in **1**.

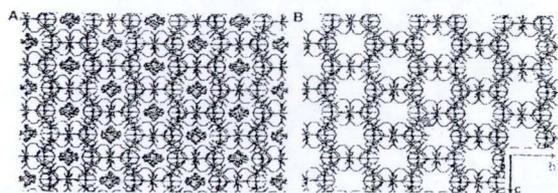

Fig. 4 (A) Channels filled with disordered perchlorate anions (shown in the space-filling mode) and water molecules. (B) Empty channels for compound **1**.

#### Crystal structure of $\{[\text{Zn}_3(4,4'\text{-bpy})_3(\mu\text{-O}_2\text{CCH}_3)_4(\text{H}_2\text{O})_2](\text{PF}_6)_2(\text{H}_2\text{O})_2\}_n$ (**2**)

The simple replacement of formate by acetate during the synthetic procedure (used to prepare **1**) produces significant structural changes in the crystal lattice of the resulting coordination compound  $\{[\text{Zn}_3(4,4'\text{-bpy})_3(\mu\text{-O}_2\text{CCH}_3)_4(\text{H}_2\text{O})_2](\text{PF}_6)_2(\text{H}_2\text{O})_2\}_n$  (**2**). As is shown in Fig. 5, **2** only exhibits two types of zinc(II) ions, namely Zn1 and Zn2 (instead of four different zinc ions for compound **1**; see above).

Zn1 is characterized by a strongly distorted octahedral coordination environment, owing to the small bite angle of the  $\mu$ -O,O',O' bridging mode of one of the two acetato ligands (the angle O3–Zn1–O4 is only 58.34(12)°; Table 2). The basal plane is constituted of four oxygen atoms belonging to two acetato ligands (O1, O3 and O4) and one water molecule (O5). The octahedron is completed by two 4,4'-bpy nitrogen atoms (N1 and N2a), at the axial positions. The Zn–O and Zn–N bond distances can be considered as normal for this type of  $\text{ZnN}_2\text{O}_4$  coordination environment (Table 2).

Zn2 lies on an inversion centre. The coordination environment around the Zn2 ion is an almost perfect octahedron, since the basal angles, varying from 87.73(13) to 92.27(13)°, are close to the ideal value of 90°. At the basal plane, Zn2 is coordinated by four oxygen atoms (O2, O3, O2c and O3c) from different acetato ligands. The axial positions are occupied by nitrogen atoms N3

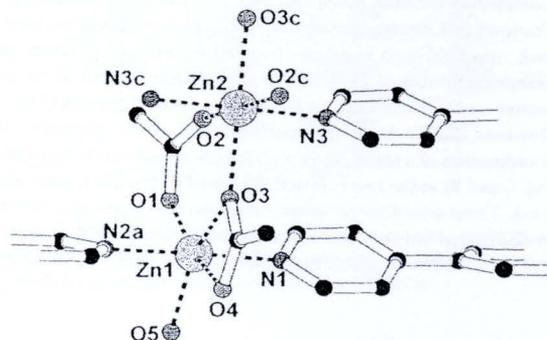

Fig. 5 Representation of the asymmetric unit of **2** showing the atom labeling scheme for the zinc(II) ions. The hexafluoridophosphate anions, the lattice water molecules and the H atoms are not shown for clarity. Symmetry operations:  $a = x, -y + 1, z$ ;  $c = 1 - x, 1 - y, 1 - z$ .

<sup>a</sup> Symmetry operations:  $a = x, -y + 1, z$ ;  $c = 1 - x, 1 - y, 1 - z$ .

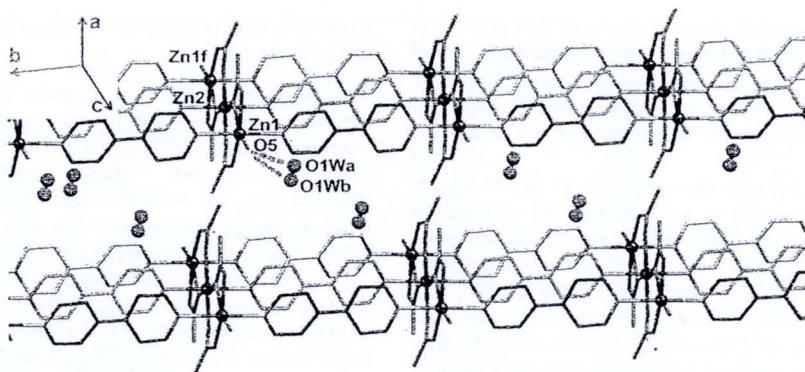

Fig. 6 1D coordination network in **2** of Zn<sup>II</sup>, 4,4'-bipyridine and acetate. The 4,4'-bpy ligands involved in the formation of trinuclear zinc units are shown in blue, green and orange for comparison with compounds **1** and **3**. Symmetry operations:  $a = x, -y + 1, z$ ;  $b = x, 1 + y, z$ ;  $f = 2 - x, 1 - y, 2 - z$ .

and N3c, belonging to two 4,4'-bpy ligands (lying on an inversion centre) at common distances.

Zn2 is bridged to two symmetry-related Zn1 ions *via* two  $\mu$ -O,O'- and two  $\mu$ -O,O'-acetato ligands, generating a linear trinuclear [Zn1, Zn2, Zn1] cluster, analogous to the [Zn1, Zn3, Zn1] triad observed in **1** (see Fig. 2 and 6).

The [Zn1, Zn2, Zn1] clusters are connected to each other through coordination of the zinc ions by 4,4'-bpy ligands, producing a 1D chain, constituted of three single zinc chains, indicated by the blue, green and yellow 4,4'-bpy ligands in Fig. 6. Contrary to **1**, the triple-stranded chains in **2** are not connected to each other through a single-stranded coordination chain (see orange chain in Fig. 2). This interconnection is most likely prevented by the steric bulk of the acetato methyl groups (Fig. 7). However, the 1D chains are closely packed, which only allows the coordination of a small molecule, namely a water molecule (O5 in Fig. 6 and 7) at the two external positions of the [Zn1, Zn2, Zn1] triad. These coordinated water molecules are hydrogen-bonded to disordered lattice water molecules ( $O5 \cdots O1Wb = 2.717(16)$  Å and  $O5 \cdots O1Wa = 2.806(19)$  Å). Similarly to the ClO<sub>4</sub><sup>-</sup> ions in **1**,

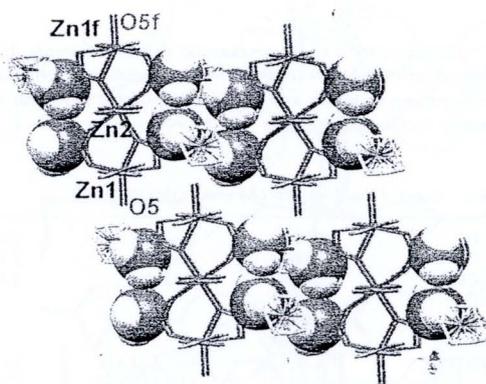

Fig. 7 Illustration of the steric bulk in **2** resulting from the acetato methyl groups (shown in the space-filling mode), which prevents the interconnection of the triple-stranded chains. Symmetry operation:  $f = 2 - x, 1 - y, 2 - z$ .

the PF<sub>6</sub><sup>-</sup> anions occupy the voids in the crystal lattice of **2** and apparently do not play a significant role in the formation of the framework (since their only interactions occur with the disordered lattice water molecules; the F $\cdots$ O contact distances are in the range 2.89(3)–2.98(2) Å). Actually, the compound  $\{[Zn_3(4,4'\text{-bpy})_3(\mu\text{-O}_2\text{CCH}_3)_4(\text{H}_2\text{O})_2](\text{ClO}_4)_2(\text{H}_2\text{O})\}_n$  has been previously reported by Woodward *et al.* (CSD refcode: CERFUB).<sup>21</sup> The X-ray structure of this compound exhibits the same 1D framework, therefore confirming the non-involvement of the PF<sub>6</sub><sup>-</sup> or ClO<sub>4</sub><sup>-</sup> anions in the network formation.

#### Crystal structure of $\{[Zn_3(4,4'\text{-bpy})_4(\mu\text{-O}_2\text{CCH}_2\text{CH}_3)_4](\text{ClO}_4)_2(4,4'\text{-bpy})_2(\text{H}_2\text{O})_4\}_n$ (**3**)

The steric effect on the molecular architecture has been further investigated by using a propionato ligand during the synthesis of the coordination assembly. Thus, the solid-state structure of compound  $\{[Zn_3(4,4'\text{-bpy})_4(\mu\text{-O}_2\text{CCH}_2\text{CH}_3)_4](\text{ClO}_4)_2(4,4'\text{-bpy})_2(\text{H}_2\text{O})_4\}_n$  (**3**), bearing ethyl groups, shows significant differences compared to that of **2** (holding CH<sub>3</sub> groups) and **1** (characterized by H groups).

The 2D molecular structure of compound **3** (Fig. 8) exhibits three different types of zinc(II) ions with octahedral N<sub>2</sub>O<sub>4</sub> (Zn1) and N<sub>3</sub>O<sub>3</sub> (Zn2, Zn3) geometries.

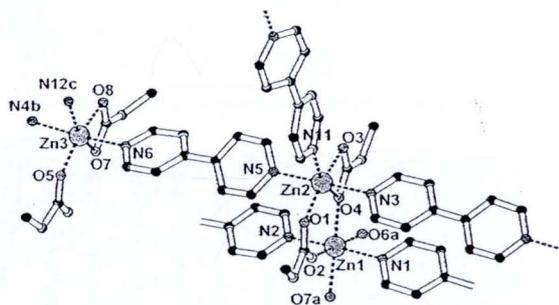

Fig. 8 Representation of the asymmetric unit of **3** showing the atom labeling scheme for the zinc(II) ions. The perchlorate anions, the lattice water molecules and the H atoms are not shown for clarity. Symmetry operations:  $a = -x, -y + 1, -z$ ;  $b = x - 1, y, z - 1$ ;  $c = -x, -y + 2, -z$ .

Zn1 exhibits an almost perfect octahedral environment with basal angles ranging from 89.22(9) to 91.47(9)° (Table 3). The basal plane is constituted of four oxygen atoms belonging to two  $\mu$ -O, $O'$ -propionato ligands (O2 and O6a) and two  $\mu$ -O, $O'$ -propionato ligands (O4 and O7a). The axial positions are occupied by two different 4,4'-bpy ligands which connect Zn1 to symmetry-related Zn1 ions, generating a polymeric chain. The Zn–N and Zn–O bond lengths are comparable to those of the ZnN<sub>2</sub>O<sub>4</sub> coordination units of the previous compounds.

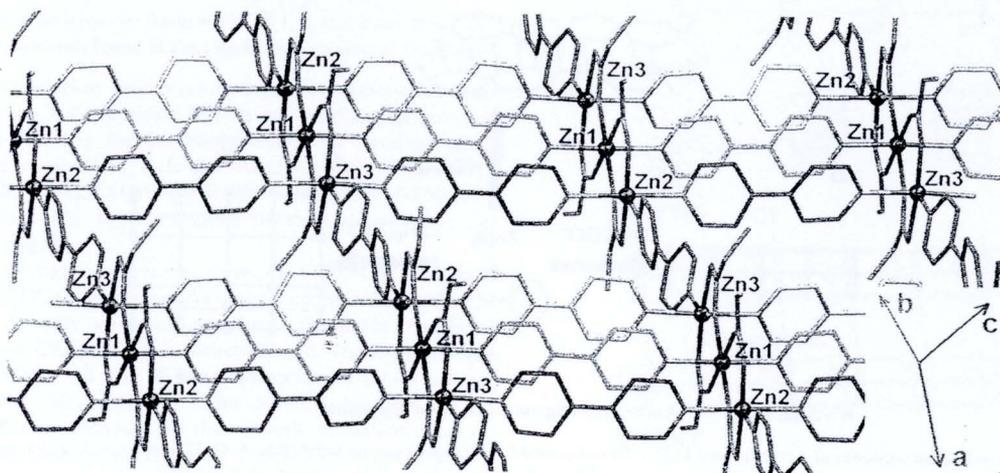

Zn2 is coordinated at the basal plane of the octahedron by three oxygen atoms and one nitrogen atom from two propionato ligands (O3, O4 and O1) and one 4,4'-bpy ligand (N11). The axial positions are occupied by two 4,4'-bpy ligands (N3 and N5), linking Zn2 to two symmetry-related Zn3 ions, generating a polymeric chain exhibiting the sequence {Zn2, Zn3, Zn2, Zn3,...}. The Zn–O and Zn–N bond distances are in normal ranges for this type of coordination moiety.<sup>24,26</sup> The basal angles

varying from 59.55(9) to 105.33(9)° (Table 3) are indicative of a strong distortion of the octahedron, attributed to the small bite angle of the  $\mu$ -O, $O'$ -propionato ligand (O4–Zn2–O3 = 59.55(9)°).

The coordination environment around the Zn3 ion is comparable to that of Zn2. The ZnN<sub>3</sub>O<sub>3</sub> unit exhibits analogous Zn–O

**Fig. 10** Illustrations of the steric hindrance due to the propionato ethyl groups (shown in the space-filling mode, in grey and light blue) in **3**, which prevents close contacts between the 1D chains.

**Fig. 9** 2D coordination network in **3** of Zn<sup>II</sup>, 4,4'-bipyridine and propionate. The 4,4'-bpy ligands involved in the formation of trinuclear zinc units are shown in blue, green and orange for comparison with compounds **1** and **2**. The 4,4'-bpy ligands connecting 1D three-leg ladders are shown in red.

and Zn–N bond lengths (to those of Zn2), which can be considered as normal (Table 3).<sup>27</sup> Similarly to Zn2, the coordination geometry around Zn3 is a strongly distorted octahedron, resulting from the small O7–Zn3–O8 angle of 59.57(9)° characterizing the coordination of the propionato ligand (Fig. 8).

The trinuclear [Zn1, Zn2, Zn3] clusters are connected to each other, in a head-to-tail fashion, through the coordination of the

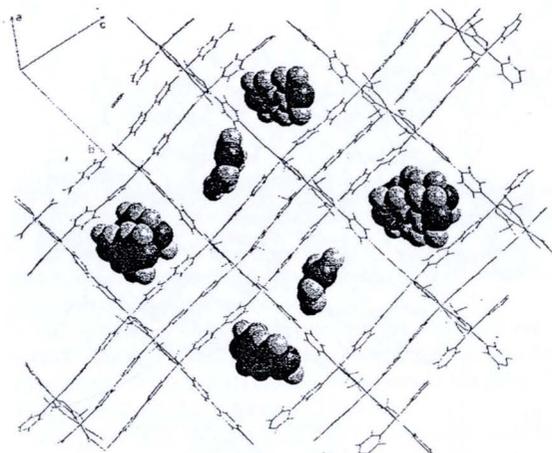

Fig. 11 Representation of the 2D network of compound 3, illustrating the large cavities which contain non-coordinated 4,4'-bpy ligands (space-filling mode).

zinc ions by 4,4'-bpy ligands, producing a 1D chain exhibiting the sequence {Zn1, Zn1, Zn1, ...} for the central metal ion and {Zn2, Zn3, Zn2, Zn3, ...} for the external zinc ions. This arrangement gives rise to triple-stranded chains, illustrated by the blue, green and yellow 4,4'-bpy ligands in Fig. 9. These coordination polymeric chains are closely related to those observed for compound 2 (see Fig. 6 and 9) and reassemble part of the network of compound 1 (see Fig. 2 and 9). In contrast to the methyl groups in 2, the ethyl groups of the propionato ligands in 3 do not allow a close packing of the triple-stranded polymeric chains (see Fig. 7 and 10), as the result of steric constraints. Consequently, the trinuclear zinc(II) units in 3 are more separated from each other than those in 2 (Fig. 7 and 10A). Indeed, the shorter intermolecular Zn...Zn separation distance is 9.391(3) Å for compound 3, while the shorter intermolecular Zn...Zn distance is 5.557(3) Å for 2.

This spatial organization allows the coordination of 4,4'-bpy ligands at the two external positions of the trizinc moieties (orange 4,4'-bpy ligands coordinated to Zn3 and Zn2; Fig. 9), connecting the triple-stranded chains to each other to form a 2D network. The herringbone-type architecture (Fig. 10A and 11) exhibit large cavities that can accommodate bulky guest molecules, namely non-coordinated 4,4'-bpy ligands which are hydrogen-bonded to lattice water molecules (N10...O1w = 2.960(8), N9...O4w = 2.908(7) Å and N8...O3w = 2.827(10) Å). In addition, these large voids contain disordered perchlorate anions, which do not significantly interact with the metal-organic framework, but are hydrogen bonded to lattice water molecules (O15...O2w = 2.889(12) Å, O12...O3w = 2.831(15) Å and O12b...O3w = 2.882(15) Å).

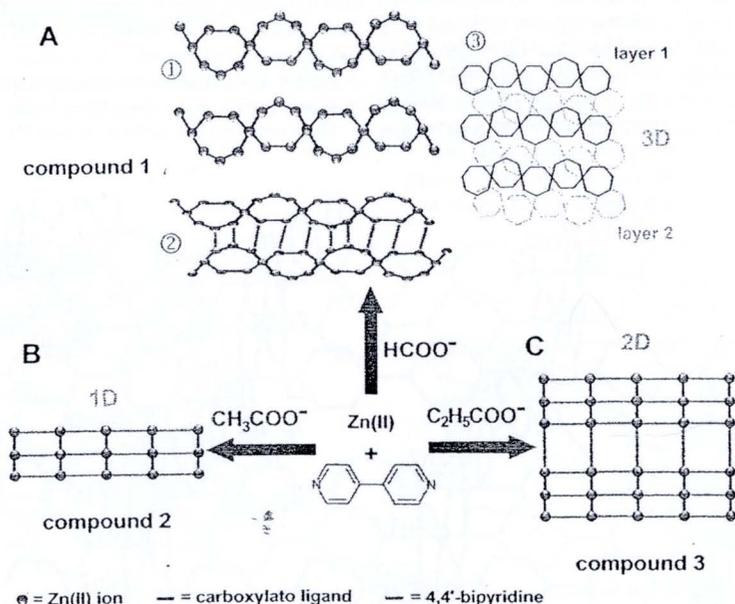

Fig. 12 Coordination networks of A) compound 1 (3D), B) compound 2 (1D) and C) compound 3 (2D). A-⊙: 1D chains packed in a parallel fashion, forming a 2D layer; A-⊕: connection of two chains through 4,4'-bpy ligands; A-⊖: packing of slightly shifted layers.

### Coordination networks

The use of slightly different carboxylato moieties as secondary co-ligands of  $[Zn(II)/4,4'\text{-bpy}]$  coordination units, applying the same reaction conditions, leads to the formation of drastically distinct networks (Fig. 12).

The combination  $[Zn^{II}/4,4'\text{-bpy}/\text{formate}]$  generates an intricate 3D framework (Fig. 12A). The bridging of zinc(II) ions by formate ligands produces a 1D chain constituted of heptanuclear rings (see Fig. 3 and 12A-⊖). These chains are arranged in a parallel fashion, resulting in a 2D layer. Each layer is linked to one layer above and to one layer below through coordinated 4,4'-bipyridines (red lines in Fig. 12A-⊖). Since each chain is connected to two chains above and to two chains below, this spatial organization creates a 3D framework of slightly shifted layers (Fig. 12A-⊙).

The sole replacement of formate by acetate results in the formation of 1D network (Fig. 12B). This simple framework is built from trinuclear acetato-bridged units that are linked to two adjacent ones, to form a three-leg ladder.

The use of propionate as co-ligand yields a 2D network (Fig. 12C) which presents similarities with the previous one. Actually, the framework of **3** contains the three-leg ladders observed in solid-state structure of **2**. These three-leg ladders are connected to each other *via* 4,4'-bpy ligands (vertical red lines in Fig. 12C).

It should be noted that, albeit the three coordination networks are different, they show some common features. Indeed, all three structures exhibit trinuclear carboxylato-bridged moieties as secondary building units (SBUs). Moreover, infinite  $\{-Zn-(4,4'\text{-bpy})-\}_n$  chains are observed for the three compounds (see for instance, the red  $\{-Zn_4-(4,4'\text{-bpy})-\}_n$  chains in Fig. 2, and the blue  $\{-Zn1/Zn2-(4,4'\text{-bpy})-\}_n$  chains in Fig. 6 and 9, respectively). Finally, one should notice that the zinc(II) ions have similar coordination environments, regardless of the carboxylato co-ligand used. Therefore, the structural diversity of the frameworks obviously originates from different steric constraints induced by the carboxylato ligands.

### Comparison between the frameworks of **1**, **2** and **3** and those of related compounds found in the Cambridge Structural Database

Eight coordination frameworks exclusively constructed from zinc(II) ions, 4,4'-bipyridine ligands and bridging carboxylato units are found in the Cambridge Structural Database (CSD ConQuest version 1.11; Refcodes: ALUPUS,<sup>14,15,28</sup> CERFOV,<sup>21</sup> CERFUB,<sup>21</sup> DELTAQ,<sup>19</sup> EYELID,<sup>17</sup> JODFIS,<sup>13</sup> NEWTIT<sup>18</sup> and QEQBIY<sup>12</sup>). Representations of these frameworks are shown in Fig. 13.

From the eight compounds, three, *i.e.* CERFOV, CERFUB and QEQBIY, show frameworks that are comparable to those of **2** and **3**. Actually, as already mentioned above, the compound with refcode CERFUB<sup>21</sup> is isostructural to **2**.<sup>3</sup> The sole difference between CERFUB and **2** lies in the distinct lattice anions, respectively,  $\text{ClO}_4^-$  and  $\text{PF}_6^-$ . This demonstrates that the two anions have no influence on the network formation. The 2D triple-chain sheet architectures of CERFOV<sup>21</sup> and QEQBIY<sup>12</sup> are comparable to that of **3**. The remaining five compounds exhibit 1D networks (ALUPUS, EYELID, JODFIS and

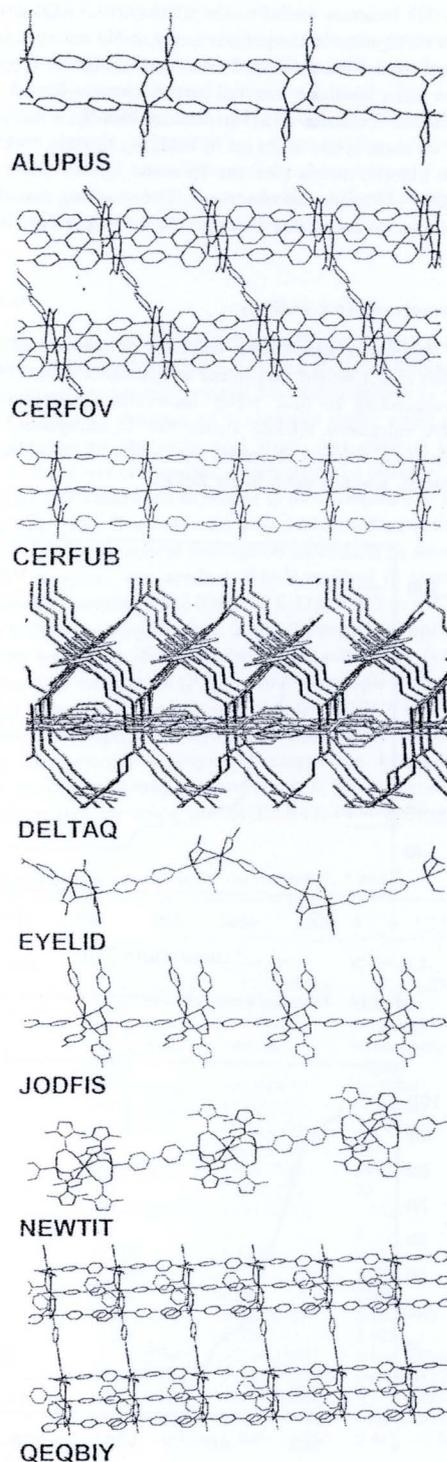

Fig. 13 Representations of the coordination networks exhibited by the seven  $[Zn^{II}/4,4'\text{-bpy}/\text{carboxylato}]$ -based compounds found in the CSD.

NEWTIT) or a 3D framework (DELTAQ). Interestingly, the only 3D structure found in the CSD (DELTAQ) contains formate co-ligands. In the present study, a 3D network is observed as well when formate is used as secondary ligand. Therefore, the lower steric hindrance exerted by the formate ligand appears to favour the formation of 3D structures. Finally, it has to be noted that all carboxylate units act as bridging ligands, linking two or three zinc(II) atoms (for the formate ligand, polymeric Zn<sup>II</sup>/HCOO<sup>-</sup> structures are observed). The resulting zinc clusters are connected to each other through the 4,4'-bipyridine ligands.

#### Thermogravimetric analysis

The thermal decomposition behavior of compound **1** (Fig. 14) reveals a first weight loss in the temperature range 143–201 °C, corresponding to four water molecules (experimental value, 5.50%; calculated, 6.03%). From 202 °C, compound **1** starts to decompose. When **1** is heated up to 800 °C, a white residue is obtained, which is most likely ZnO.

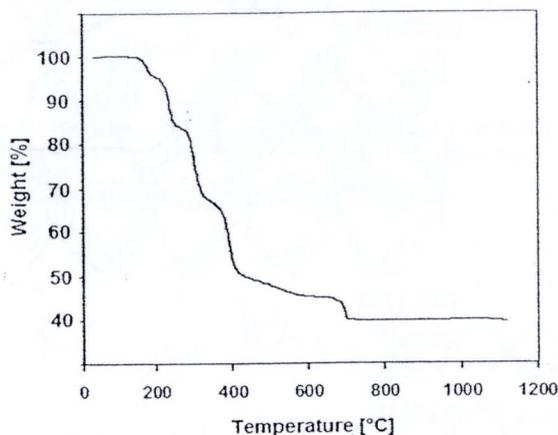

Fig. 14 Thermogravimetric analysis of compound **1**.

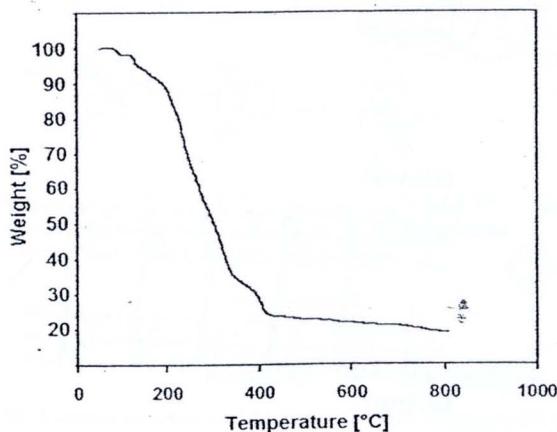

Fig. 15 Thermogravimetric analysis of compound **2**.

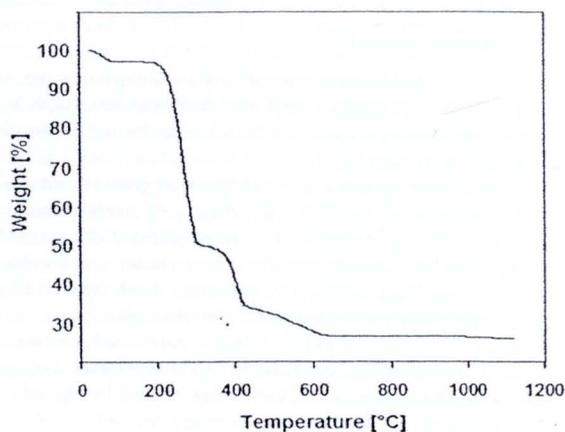

Fig. 16 Thermogravimetric analysis of compound **3**.

The thermogravimetric analysis of compound **2** (Fig. 15) shows a first weight loss in the temperature range 71–170 °C, characterizing the loss of four water molecules (experimental value, 5.82%; calculated, 5.70%). In the temperature range 171–429 °C, the decomposition of the coordination material is observed. As for **1**, a white residue (ZnO) is obtained when **2** is heated to 800 °C.

The thermal analysis of **3** (Fig. 16) exhibits a two-stage decomposition of the material. A first weight loss of 3.50% is observed in the temperature range 92–195 °C, which corresponds to the release of four lattice water molecules (calculated 4.15%). In the temperature range 196–630 °C, compound **3** degrades. As for compounds **1** and **2**, a white residue (ZnO) is obtained when the sample is heated to 800 °C.

#### Conclusions

One of the most important challenges that remains in crystal engineering is crystal structure prediction. As properly stated by Desiraju,<sup>29</sup> the main objective of the crystal engineering chemist is to try to understand intermolecular interactions in the context of crystal packing and to use such knowledge to rationally design new materials with anticipated molecular structures and desired physical and chemical properties.

In the present study, the influence of small secondary ligands, namely common monocarboxylate ligands, on the overall solid-state structure of [zinc(II)-4,4-bpy-carboxylate] coordination compounds has been investigated. This study shows that the change from a formate ligand to an acetate and a propionate ligand gives rise to the formation of drastically distinct metal-organic frameworks, as the result of the different steric bulk of the carboxylate unit involved. Such studies are of great interest for the crystal engineering chemist, as they contribute to increase the knowledge about crystallization processes and molecular structure prediction.

#### Experimental

All starting materials were commercially available and used as received. IR spectra were recorded on a Perkin-Elmer Spectrum

One FTIR spectrophotometer as KBr discs in the range 4000–450  $\text{cm}^{-1}$ . C, H, and N analyses were performed on a Perkin-Elmer PE2400 CHNS/O. Thermogravimetric analyses were carried out using a Perkin-Elmer Pyris Diamond analyzer in flowing nitrogen at a heating rate of 10  $^{\circ}\text{C min}^{-1}$ . X-ray powder diffraction (XRPD) data for **1–3** were obtained using a Phillips Xpert Pro equipped with an X'celerator, with Cu K $\alpha$  radiation ( $\lambda \approx 1.5408 \text{ \AA}$ ), in the  $2\theta$  range 10–45. The diffraction patterns were recorded at room temperature (see Fig. S1–S3, ESI).†

#### Synthesis of $\{[\text{Zn}_3(4,4'\text{-bpy})_{3.5}(\mu\text{-O}_2\text{CH})_4(\text{H}_2\text{O})_2](\text{ClO}_4)_2(\text{H}_2\text{O})_2\}_n$ (**1**)

An aqueous solution (10 mL) of  $\text{Zn}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$  (0.302 g, 1.0 mmol) was added to an ethanolic solution (10 mL) of **4,4'-bpy** (0.157 g, 1.0 mmol). An aqueous solution (10 mL) of  $\text{NaO}_2\text{CH}$  (sodium formate; 0.149 g, 2.0 mmol) was subsequently added, followed by 0.141 g of  $\text{KClO}_4$  (1.0 mmol) under continuous stirring. The resulting colourless solution was allowed to stand unperturbed for the slow evaporation of the solvent at room temperature. After several days, colourless crystals were obtained. The crystals were filtered, washed with the mother liquid and dried in air. Yield = 0.262 g (66% based on Zn). Elemental analyses calculated for  $\text{C}_{39}\text{H}_{40}\text{Cl}_2\text{N}_7\text{O}_{20}\text{Zn}_3$ : C, 39.24; H, 3.38; N, 8.21. Found: C, 39.22; H, 3.31; N, 8.22%. IR data ( $\text{cm}^{-1}$ ): 3400s, 1609s, 1588s, 1536w, 1413m, 1384m, 1348w, 1224w, 1117s, 1089s, 807s, 630s. The purity and homogeneity of compound **1** were confirmed by X-ray powder diffraction (see Fig. S1).†

#### Synthesis of $\{[\text{Zn}_3(4,4'\text{-bpy})_3(\mu\text{-O}_2\text{CCH}_3)_4(\text{H}_2\text{O})_2](\text{PF}_6)_2(\text{H}_2\text{O})_2\}_n$ (**2**)

An aqueous solution (15 mL) of  $\text{Zn}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$  (0.306 g, 1.0 mmol) was added to a solution of **4,4'-bpy** (0.157 g, 1.0 mmol) in ethanol (10 mL). Next, an aqueous solution (20 mL) of  $\text{NaO}_2\text{CCH}_3$  (sodium acetate; 0.138 g, 2.0 mmol) and an aqueous solution (10 mL) of  $\text{KPF}_6$  (0.185 g, 1.0 mmol) were added under continuous stirring. A few drops of  $\text{CH}_3\text{COOH}$  98% were subsequently added to the reaction mixture, yielding a clear colorless solution. This solution was allowed to stand unperturbed for the slow evaporation of the solvent at room temperature, producing colorless needle crystals of **2** after a few days. Yield = 0.290 g (70% based on Zn). Elemental analyses calculated for  $\text{C}_{38}\text{H}_{44}\text{F}_{12}\text{N}_6\text{O}_{12}\text{P}_2\text{Zn}_3$ : C, 36.14; H, 3.51; N, 6.66. Found: C, 36.41; H, 3.24; N, 6.30%. IR data ( $\text{cm}^{-1}$ ): 3400s, 3045s, 1603s, 1520s, 1490s, 1419s, 133m, 1219s, 1070s, 1195s, 1100s, 1074s, 1046m, 1015m, 846s, 838s, 643m, 630m, 560s. The purity and homogeneity of compound **2** were confirmed by X-ray powder diffraction (see Fig. S2).†

#### Synthesis of $\{[\text{Zn}_3(4,4'\text{-bpy})_4(\mu\text{-O}_2\text{CCH}_2\text{CH}_3)_4](\text{ClO}_4)_2(4,4'\text{-bpy})_2(\text{H}_2\text{O})_4\}_n$ (**3**)

An aqueous solution (10 mL) of  $\text{Zn}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$  (0.313 g, 1.0 mmol) was added to a solution of **4,4'-bpy** (0.158 g, 1.0 mmol) in ethanol (10 mL). Subsequently, an aqueous solution (10 mL) of  $\text{NaCOOCH}_2\text{CH}_3$  (sodium propanoate; 0.201 g, 2.0 mmol) was added, followed by  $\text{KClO}_4$  (0.152 g, 1.0 mmol) under continuous stirring. Next, a few drops of  $\text{CH}_3\text{CH}_2\text{COOH}$  98% were added,

yielding a clear colourless solution, which was allowed to stand unperturbed for the slow evaporation of the solvent at room temperature. Colorless crystals were collected from the solution by filtration after several days. Yield = 0.385 g (68% based on Zn). Elemental analyses calculated for  $\text{C}_{72}\text{H}_{76}\text{Cl}_2\text{N}_{12}\text{O}_{20}\text{Zn}_3$ : C, 50.97; H, 4.52; N, 9.91. Found: C, 51.19; H, 4.84; N, 9.91%. IR data ( $\text{cm}^{-1}$ ): 3392s, 1609s, 1578s, 1552s, 1466m, 1419m, 1222w, 1107s, 1067s, 1046m, 808s, 631s. The purity and homogeneity of compound **3** were confirmed by X-ray powder diffraction (see Fig. S3).†

#### Crystallography

The X-ray single-crystal data for all compounds were collected at 293(2) K on a 4 K Bruker SMART CCD area detector diffractometer using graphite monochromated Mo K $\alpha$  radiation ( $\lambda = 0.71073 \text{ \AA}$ ) at a detector distance of 4.5 cm and swing angle of  $-35^{\circ}$ . A hemisphere of the reciprocal space was covered by combination of three sets of exposures; each set had a different  $\phi$  angle (0, 88, and  $180^{\circ}$ ) and each exposure of 40 s covered  $0.3^{\circ}$  in  $\omega$ . Data reduction and cell refinements were performed using the program SAINT.<sup>30</sup> An empirical absorption correction by using the SADABS<sup>31</sup> program was applied, which resulted in transmission coefficients ranging from 0.690 to 0.820, 0.642 to 0.823 and 0.600 to 0.680 for compounds **1**, **2** and **3**, respectively. The structures were solved by direct methods and refined by full-matrix least-squares method on  $(F_{\text{obs}})^2$  with anisotropic thermal parameters for all non-hydrogen atoms using the SHELXL-PC V 6.12 software package.<sup>32</sup> All hydrogen atoms were located geometrically and refined isotropically except the hydrogen atoms of the propionate group in compound **3**. The molecular graphics were created by using the SHELXL-PC<sup>32</sup> package.

The crystal and refinement details of all compounds are listed in Table 4.

For compound **1**, displacement parameter restraints were used in modelling the perchlorates and the bpy ligands. Even with these, the displacement parameter ratio (maximum) of a few atoms is around 4.5 : 1, and the anisotropic parameters for the perchlorate are larger than ideal. Geometric restraints were used in modelling the chlorates.

First published as an Advance Article on the web XXX

Three porous crystalline coordination polymers, *i.e.* the three-dimensional framework  $\{[Zn_3(4,4'\text{-bpy})_3(\mu\text{-O}_2\text{CH})_4(\text{H}_2\text{O})_2](\text{ClO}_4)_2(\text{H}_2\text{O})_2\}_n$  (**1**), the one-dimensional three-leg ladder  $\{[Zn_3(4,4'\text{-bpy})_3(\mu\text{-O}_2\text{CCH}_3)_4(\text{H}_2\text{O})_2](\text{PF}_6)_2(\text{H}_2\text{O})_2\}_n$  (**2**), and the two-dimensional layered network  $\{[Zn_3(4,4'\text{-bpy})_4(\mu\text{-O}_2\text{CCH}_2\text{CH}_3)_4](\text{ClO}_4)_2(4,4'\text{-bpy})_2(\text{H}_2\text{O})_4\}_n$  (**3**), have been investigated. All networks exhibit voids that contain the counter-ions and guest molecules, namely water for compounds **1** and **2**, and water/4,4'-bpy for compound **3**. In addition, compounds **2** and **3** are further stabilized by hydrogen bonds and  $\pi$ - $\pi$  stacking interactions to form intricate supramolecular frameworks. The removal and reintroduction of guest water molecules for compounds **2** and **3** have been explored for their dynamic structural transformation. Interestingly, all Zn(II) compounds are active heterogeneous catalysts for the high-yield cyanosilylation of acetaldehyde in dichloromethane.

## Introduction

Porous coordination polymers (PCPs), also known as metal-organic frameworks (MOFs), may be assembled from various molecular building blocks; therefore, diverse architectures and functions can be achieved.<sup>1-3</sup> MOFs may find potential applications in molecular adsorption and separation processes,<sup>1-3</sup> ion-exchange,<sup>4,6</sup> catalysis,<sup>7</sup> sensor technology,<sup>8</sup> and optoelectronics.<sup>9</sup> The design of porous coordination polymers does not only allow the preparation of light materials with high porosity, but also the generation of desirable regular networks. PCPs are engineered by linking building blocks at their coordination sites via multifunctional linkers into perfect and esthetic architectures, whose topology is pre-defined by the arrangement of the coordination sites and the orientation and number of the binding groups in the linker. Despite extensive studies, applications of porous compounds are still quite limited compared to that of zeolites. Inorganic materials with inner cavities, such as zeolites are known to bind many organic molecules in the hollow spaces and often exhibit unique catalytic properties for a number of organic reactions, in which high regioselectivity, stereoselectivity, and shape selectivity are observed.<sup>10-15</sup> Reports of catalytic studies involving coordination polymers have been relatively scarce.<sup>16-29</sup> While most of these investigations have dealt with some significant successes in enantioselective catalysis,<sup>17, 18</sup> there has been little focus thus far on probing the selectivity with substrates of comparable size to the pore dimensions.<sup>27, 29</sup>

Only few catalytic applications of carboxylato-bridged porous coordination polymers have been reported.<sup>4,7</sup> The catalytic and dynamic structural transformation of three coordination polymeric architectures for which preliminary results were published,<sup>30</sup> namely the 3D  $\{[Zn_3(4,4'\text{-bpy})_3(\mu\text{-O}_2\text{CH})_4(\text{H}_2\text{O})_2](\text{ClO}_4)_2(\text{H}_2\text{O})_2\}_n$  (**1**), the 1D  $\{[Zn_3(4,4'\text{-bpy})_3(\mu\text{-O}_2\text{CCH}_3)_4(\text{H}_2\text{O})_2](\text{PF}_6)_2(\text{H}_2\text{O})_2\}_n$  (**2**) and the 2D  $\{[Zn_3(4,4'\text{-bpy})_4(\mu\text{-O}_2\text{CCH}_2\text{CH}_3)_4](4,4'\text{-bpy})_2(\text{ClO}_4)_2(\text{H}_2\text{O})_4\}_n$  (**3**), are herein reported.

## Experimental Section

### Preparation of the coordination polymers

*Synthesis of  $\{Zn_3(4,4'\text{-bpy})_3(\mu\text{-O}_2\text{CH})_4(\text{H}_2\text{O})_2(\text{ClO}_4)_2(\text{H}_2\text{O})_2\}_n$  (**1**)*<sup>30</sup>

An aqueous solution (10 mL) of  $Zn(NO_3)_2 \cdot 6H_2O$  (0.302 g, 1.0 mmol) was added to an ethanolic solution (10 mL) of 4,4'-bpy (0.157 g, 1.0 mmol). An aqueous solution (10 mL) of NaCOOH (sodium formate; 0.149 g, 2.0 mmol) was subsequently added, followed by 0.141 g of  $KClO_4$  (1.0 mmol) under continuous stirring. The resulting colorless solution was allowed to stand unperturbed for the slow evaporation of the solvent at room temperature. After several days, colorless crystals were obtained. The crystals were filtered, washed with the mother liquid and dried in air. Yield = 68 %.

*Synthesis of  $\{Zn_3(4,4'\text{-bpy})_3(\mu\text{-O}_2\text{CCH}_3)_4(\text{H}_2\text{O})_2(\text{PF}_6)_2(\text{H}_2\text{O})_2\}_n$  (**2**) and  $\{Zn_3(4,4'\text{-bpy})_4(\mu\text{-O}_2\text{CCH}_2\text{CH}_3)_4(4,4'\text{-bpy})_2(\text{ClO}_4)_2(\text{H}_2\text{O})_4\}_n$  (**3**)*<sup>30</sup>

Complexes **2** and **3** have also been obtained following the synthetic procedure applied for compound **1**, using sodium acetate for **2** and sodium propionate for **3** in place of sodium formate (compound **1**). Yield = 78 % (**2**) and 70 % (**3**).

*Synthesis of  $\{Zn_3(4,4'\text{-bpy})_3(\mu\text{-O}_2\text{CH})_4(\text{H}_2\text{O})_2(\text{ClO}_4)_2(\text{H}_2\text{O})_2\}_n$  (**1**) doped with  $Cu^{2+}$  (**1a**) and  $Mn^{2+}$  (**1b**)*

An aqueous solution (10 mL) of  $Zn(NO_3)_2 \cdot 6H_2O$  (0.308 g, 1.0 mmol) was added to an ethanolic solution (10 mL) of 4,4'-bpy (0.158 g, 1.0 mmol). An aqueous solution (10 mL) of NaCOOH (sodium formate; 0.148 g, 2.0 mmol) was subsequently added, followed by 0.141 g of  $KClO_4$  (1.0 mmol) and 0.003 g (0.002 mmol) of  $Cu(NO_3)_2 \cdot 3H_2O$  (or 0.003 g  $Mn(NO_3)_2 \cdot 4H_2O$  (0.002 mmol)) under continuous stirring. The resulting solution was allowed to stand unperturbed for the slow evaporation of the solvent at room temperature. After several days, light-green crystals of **1a** were obtained (light-pink crystals for **1b**). The crystals were filtered, washed with the mother liquor and dried in air. Yield = 66 %. The IR spectra of **1a** and **1b** are similar to that of **1**.

*Synthesis of  $\{Zn_3(4,4'\text{-bpy})_3(\mu\text{-O}_2\text{CCH}_3)_4(\text{H}_2\text{O})_2(\text{PF}_6)_2(\text{H}_2\text{O})_2\}_n$  (**2**) and  $\{Zn_3(4,4'\text{-bpy})_4(\mu\text{-O}_2\text{CCH}_2\text{CH}_3)_4(4,4'\text{-bpy})_2(\text{ClO}_4)_2(\text{H}_2\text{O})_4\}_n$  (**3**) doped with  $Cu^{2+}$  and  $Mn^{2+}$ , **2a**, **2b**, **3a** and **3b***

Complexes **2a**, **2b**, **3a** and **3b** can also be obtained applying the same synthetic procedure as for **1a** and **1b**, using sodium acetate and  $\text{Cu}^{2+}$  for **2a** ( $\text{Mn}^{2+}$  for **2b**) and potassium propionate and  $\text{Cu}^{2+}$  for **3a** ( $\text{Mn}^{2+}$  for **3b**). The IR spectra of the doped compounds are comparable to those of the corresponding parent compounds, respectively **2** and **3**.

#### Characterization

FTIR spectra were recorded on a Perkin–Elmer Paragon 1000 FTIR spectrophotometer, equipped with a Golden Gate ATR device, using the reflectance technique ( $4000\text{--}300\text{ cm}^{-1}$ ). Elemental analyses for C, H and N were performed with a Perkin–Elmer 2400 analyzer. Thermogravimetric analyses were carried out using a Perkin–Elmer Pyris Diamond analyzer in flowing nitrogen at a heating rate of  $10\text{ }^\circ\text{C min}^{-1}$ . The X-band powder EPR spectra were obtained on polycrystalline samples at room temperature and at  $77\text{ K}$  with a Bruker EMXplus spectrometer with DPPH ( $g = 2.0036$ ) as a reference. X-ray powder diffraction (XRPD) data were recorded at room temperature using a Phillips Xpert Pro equipped with an X'celerator, with  $\text{Cu K}\alpha$  radiation ( $\lambda \approx 1.5408\text{ \AA}$ ), in the  $2\theta$  range  $10\text{--}45^\circ$ .

#### Catalytic Reactions

A typical cyanosilylation reaction was performed as follows:  $40\text{ mg}$  ( $0.006\text{ mmol}$ ,  $0.2\text{ mmol}$  of Zn) of MOF catalyst was suspended in  $5\text{ mL}$  of dry dichloromethane ( $\text{CH}_2\text{Cl}_2$ ) or tetrahydrofuran (THF), followed by the addition of the aldehyde ( $1.5\text{ mmol}$ ) and trimethylsilyl cyanide ( $3\text{ mmol}$ ). The reaction mixtures were stirred at room temperature under argon. The reaction conversions were determined by gas chromatography (GC) analysis. The catalytic recyclability was checked three times with the same batch of catalyst, and no obvious decrease in activity was observed. For the filtration test, the catalyst was separated after a reaction time of  $5\text{ h}$  and the solution was divided into two equal portions. Hereafter, one portion was stirred with fresh catalyst, while the second one was stirred without MOF catalyst.

## Results and Discussion

#### Synthesis and Structure

Crystalline materials were obtained for all three compounds prepared from zinc(II) ions,  $4,4'$ -bpy and carboxylate ligands in ethanol/ $\text{H}_2\text{O}$  solvent mixture. Other solvent combinations were used, *i.e.* methanol/ $\text{H}_2\text{O}$  and acetone/ $\text{H}_2\text{O}$ , but the solvent pair ethanol/ $\text{H}_2\text{O}$  gave the best result in terms of yield and quality of crystals. The three compounds exhibit different topologies, induced by the different carboxylate ligands used.<sup>30</sup> The MOF compounds are insoluble in most organic solvents, except dimethyl sulfoxide and  $N,N'$ -dimethylformamide.

The combination  $\text{Zn(II)}/4,4'$ -bpy/formate generates an intricate 3D framework of **1**. The bridging of zinc(II) ions by formate ligands produces a 1D chain constituted of heptanuclear rings (Fig. 1A). The complete replacement of formate by acetate results in the formation of a 1D network (compound **2**; Fig. 1B). This simple framework is built from trinuclear acetato-bridged units that are linked to two adjacent ones, to form a three-leg ladder. The use of propionate as co-ligand yields a 2D network (Fig. 1C) which presents similarities with **2**. In fact, the framework of **3** contains the three-leg ladders observed in the solid-state structure of **2**. In **3**, these three-leg ladders are further connected to each other via  $4,4'$ -bpy ligands.

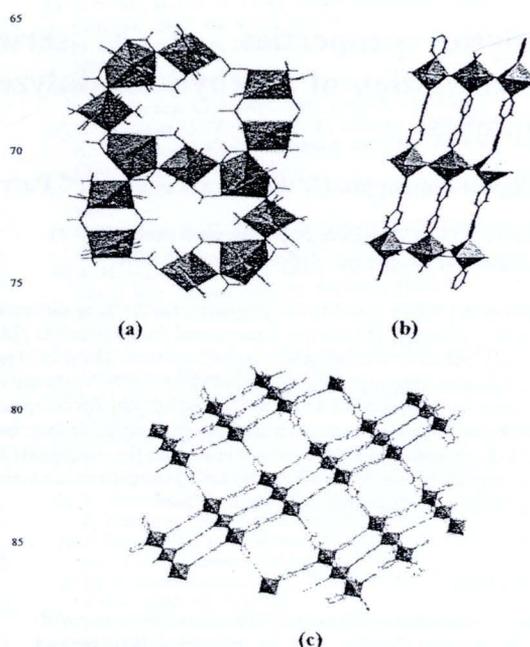

Fig. 1 (a) Perspective view of the 3D framework of **1**; (b) perspective view of the 1D three-leg ladder observed for **2** and; (c) perspective view of a 2D layer of **3**. The counter anions and the lattice water molecules have been omitted for clarity.

#### Zn(II) Compounds Doped with Cu(II) and Mn(II)

The three zinc(II) compounds were prepared in the presence of doping amounts of paramagnetic metal ions ( $\text{Cu(II)}$  and  $\text{Mn(II)}$ ) to investigate the potential cation-exchange properties of MOFs with structure retention, and analyze the coordination geometry(ies) around the  $\text{Zn(II)}$  ions. The doped materials were prepared in ethanol/ $\text{H}_2\text{O}$ , using  $\text{Zn(II)}/\text{Cu(II)}$  and  $\text{Zn(II)}/\text{Mn(II)}$  ratios of  $95:5$ , and in the presence of one equivalent of  $4,4'$ -bpy ligand. All doped compounds have been characterized by XRPD, IR spectroscopy and EPR at RT and  $70\text{ K}$  (see Figs. S1–S3). The IR spectra of the doped compounds are similar to that of the original  $\text{Zn(II)}$  compound, thus indicating that the structure and therefore the environment around the zinc(II) centers are not altered.

For instance, the polycrystalline EPR spectrum of the trinuclear  $\text{Zn(II)}$  compound **2** doped with  $\text{Cu(II)}$  shows signals revealing the presence of two different types of  $\text{Cu(II)}$  species. Each one is characterized by a four-lines hyperfine pattern with  $g_{\parallel} = 2.343$  and  $2.275$ ; (with  $A_{\parallel} = 124$  and  $126$ ; red and blue dots in Fig. 2a)  $g_{\perp} = 2.094$  and  $2.094$  in agreement with a distorted-octahedral geometry.<sup>31</sup> No super-hyperfine splitting is resolved. These EPR data are clearly indicative of the occurrence of two different environments for the  $\text{Zn(II)}$  ions in **2**, which have been replaced by  $\text{Cu(II)}$  ions. Actually, a close observation of the molecular structure of **2** clearly reveals the presence of two distinct coordination geometries for the zinc ions, a highly distorted octahedron (site I in Fig. 2b) and a perfect octahedron (site II in Fig. 2b).<sup>13</sup> Each trinuclear zinc unit in **2** is formed by two external sites I and one central site II. The doping with  $\text{Mn(II)}$  ions leads to a heteronuclear compound, whose EPR spectrum shows only one set of six lines, characterizing a  $\text{Mn(II)}$

species (Fig. 3a). These data suggest that only one from the two potential coordination sites has experienced ion exchange. Most likely Mn(II) ions are only capable of occupying site II (Fig. 3b), since Mn(II) has the tendency to form regular octahedral complexes. The polycrystalline EPR spectra of **1** and **3** doped with Cu(II) and Mn(II) exhibit similar features, thus suggesting comparable ion-exchange properties (Fig. S1).

The influence of the nature of the doping metal ion, namely Cu(II) and Mn(II), has been successfully investigated by EPR. This study illustrates the flexibility of the coordination geometry of Cu(II) compared to Mn(II). Such investigations are of great interest in the context of potential cation-exchange properties of MOFs with structure retention.

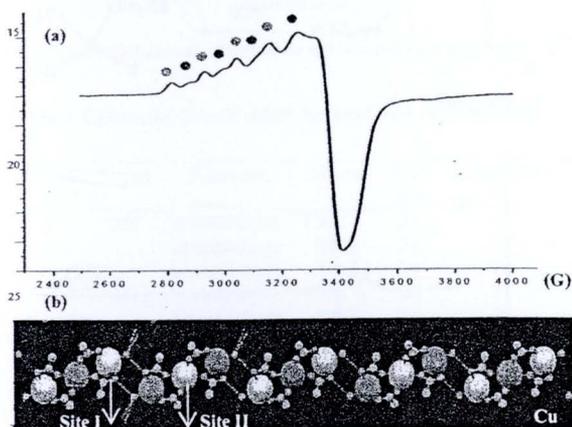

Fig. 2. (a) Polycrystalline EPR spectrum of **2** doped with Cu(II), recorded at 70 K. The two species are illustrated by blue and red dots. (b) Trinuclear Zn(II) units of **2** where zinc(II) ions (pink) have been replaced by Cu(II) ions (green) in two different sites (sites I and II).

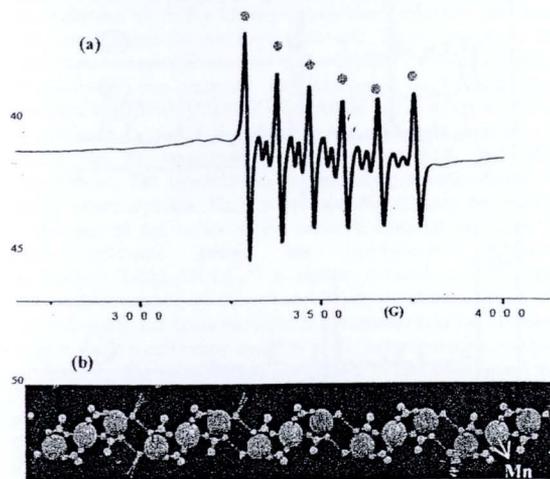

Fig. 3. (a) Polycrystalline EPR spectrum of **2** doped with Mn(II), recorded at 70 K and (b) trinuclear Zn(II) unit of **2** where only the central Zn(II) sites have been replaced by Mn(II) ions.

#### Removal and Reintroduction of Guest Molecules

The single-crystal X-ray structures of **1-3** reveal the presence of lattice water molecules, indicating a potential porosity of the

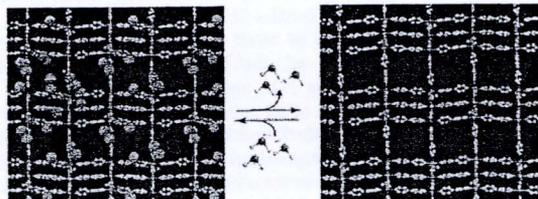

materials. Thus, all three room-temperature stable compounds exhibit open channels that are occupied by guest water molecules. The possibility of generating microporous frameworks by removing the guest molecules has therefore been investigated. Hence, the stability of the different frameworks upon removal/reintroduction of the guest molecules has been monitored in detail, using TGA and XRPD techniques.

In the TGA curves of all compounds,<sup>30</sup> the first weight loss of 5.50% for **1**, 5.82% for **2** and 3.50% for **3** in the temperature range 71–201 °C, corresponds to the loss of the coordinated waters and guest water molecules. The loss of the coordinated aqua ligands is not observed below about 180 °C, apparently as the result of their strong coordination to the Zn(II) centers. Upon evacuation at 140 °C for 8 h under reduced pressure, compounds **2** and **3** experience weight losses consistent with the removal of all water molecules, behaving as second generation porous coordination polymers which have rigid vacant channels formed after the removal of guest molecules (Scheme 1) as is clear from the main peaks of XRPD patterns.<sup>32</sup> While the weight losses of compound **1** consist of all water molecules and four formate groups when elevating the temperature to 140 °C for 8 h under vacuum, the loss four formate groups does affect the framework skeleton. X-ray power diffraction reveals the structure change, but this compound remains a microcrystalline solid, as evidence by XRPD pattern (Fig. 4A) according to the result of the elemental analysis and corresponds to the formula of Zn(4,4'-bpy)<sub>2.5</sub>(ClO<sub>4</sub>)<sub>2</sub>, calcd.: C 45.86, H 3.07, N 10.70; found: C 44.67, H 3.01, N 10.56. (Table 1). So, the zinc(II)-formate compound **1** containing 4,4'-bpy organic ligand is unstable at high temperature. On the other hand after removal of the guest molecules from crystalline **3**, the XRPD pattern of the resulting material **3c** is almost identical to the theoretical one of starting material **3** (Fig. 4C). These data clearly suggest that **3c** exhibits the original structure of **3** with empty channels. This behavior is also observed for compound **2** (Fig. 4B), therefore indicating that the solid-state structures of **2** and **3** do not collapse when the water molecules are taken out. Interestingly, the guest water species can be reintroduced into the evacuated samples of the three compounds by simple immersion in water for 48 h, as confirmed by XRPD measurements (Fig. 4), and elemental analyses (Table 1). In case of compound **1**, the elemental analysis data after reintroduction of water indicates the formula to be Zn(4,4'-bpy)<sub>2</sub>(H<sub>2</sub>O)(ClO<sub>4</sub>)<sub>2</sub>, calcd.: C 40.39, H 3.05, N 9.42; found: C 41.43, H 3.50, N 8.96 (Table 1). Thus, after removal of the water/formate molecules, the microporous solids Zn(4,4'-bpy)<sub>2.5</sub>(ClO<sub>4</sub>)<sub>2</sub> (**1c**), {Zn<sub>3</sub>(4,4'-bpy)<sub>3</sub>(μ-O<sub>2</sub>CCH<sub>3</sub>)<sub>4</sub>(PF<sub>6</sub>)<sub>2</sub>}<sub>n</sub> (**2c**) and {Zn<sub>3</sub>(4,4'-bpy)<sub>4</sub>(μ-O<sub>2</sub>CCH<sub>2</sub>CH<sub>3</sub>)<sub>4</sub>(ClO<sub>4</sub>)<sub>2</sub>(4,4'-bpy)<sub>2</sub>}<sub>n</sub> (**3c**)

Table 1 Elemental analyses of compounds **1-3** and of the products after removal and after reintroduction of the guest water molecules.

are generated with retention of the original frameworks (of compounds 2 and 3). Such microporous materials with high-thermal stabilities and host-guest properties are relatively rare and have therefore great potential for practical applications.

### 15 Catalytic properties

Porous MOFs 1-3 have been tested as heterogeneous catalysts for the cyanosilylation of acetaldehyde and benzaldehyde. Thus, the selectivity and activity of the 3D (1), 1D (2) and 2D (3) coordination polymers have been examined. Typically, the powdered catalyst (1-3) is suspended in dichloromethane ( $\text{CH}_2\text{Cl}_2$ ) or tetrahydrofuran (THF). The aldehydic substrate and trimethylsilyl cyanide (1:2 molar ratio) are subsequently added at room temperature and the reaction is carried out for 24 h (Scheme 2).<sup>27, 29</sup> The course of the reactions has been monitored by gas chromatography (GC).

Blank reactions have been performed by carrying the cyanosilylation of acetaldehyde and benzaldehyde without catalyst, at 25 °C. These test reactions give only conversions of 18% for acetaldehyde and 10% for benzaldehyde, after a reaction time of 24 h. When 40 mg of solid 1 is used as catalyst, a conversion of 95% of acetaldehyde is reached after 24 h reaction time in  $\text{CH}_2\text{Cl}_2$  (Table 3 and Fig. 5). This high conversion suggests first that 1 acts as a very efficient catalyst for this reaction, and that both acetaldehyde and trimethylsilyl cyanide can diffuse swiftly through the pores to attain the Lewis metallic sites, to generate 2-(methylsiloxy)propionitrile with a yield of 95% (71% when using 2 and 86% with 3).

When benzaldehyde, a sterically more demanding substrate, is used under similar reaction conditions, a conversion of only 22% is observed (21% for 2 and 22% for 3; Table 3). This significantly lower reactivity suggests that the dimension of the channels of the MOF plays an important role and leads to size selectivity.

Next, the influence of another organic solvent, namely THF, on the conversion of acetaldehyde has been examined for each MOF catalyst. It has been found that the reaction is less efficient in THF, which may be explained by a competitive binding of the substrate and the solvent to the metal site. This competitive binding obviously does not occur with  $\text{CH}_2\text{Cl}_2$ .

For instance, in THF, compound 1 promotes the conversion of only 38% acetaldehyde (30% for 2 and 57% for 3; Table 3). The cationic nature and Lewis acidity of the  $\text{Zn}^{2+}$  center may play a role and lead to significantly different in the conversion (Fig. 6).

In contrast to the reactions performed in  $\text{CH}_2\text{Cl}_2$ , 3 is more efficient than 1 in THF (Table 3). These disparities regarding the distinct catalytic activities in  $\text{CH}_2\text{Cl}_2$  and THF may be explained by structural features characterizing both compounds. As reported earlier,<sup>13</sup> the 3D framework of 1 exhibits channels filled by disordered perchlorate anions. The crystal packing of the 2D framework of 3 generates huge cavities filled with non-

coordinated 4,4'-bipyridine (4,4'-bpy) molecules. Most likely, the slightly more polar solvent THF is capable of displacing the 4,4'-bpy guest molecules of 3 (which is obviously not the case with  $\text{CH}_2\text{Cl}_2$ ), therefore increasing the accessibility of the aldehydic substrate to the metal centers.

The catalytic activities of compounds 1-3 for the cyanosilylation of aldehydes have been compared with those of other porous coordination frameworks. Fujita and co-workers reported the first coordination polymeric catalyst, *i.e.*  $\{\text{Cd}(4,4'$ -

		benzaldehyde	CH <sub>2</sub> Cl <sub>2</sub>	24	22

bpy)<sub>2</sub>(NO<sub>3</sub>)<sub>2</sub>},<sup>23</sup> for the cyanosilylation of aldehydes. This square network material is highly shape-selective, which is illustrated by the inclusion of *ortho*-dihalogenobenzenes, whereas the *meta*- and *para*-isomers do not form clathrates. Shape specificity has been observed as well with this compound for the cyanosilylation of aldehydes. For example, the conversion of 2-tolualdehyde (40%) is significantly higher than that of 3-tolualdehyde (19%). In addition,  $\alpha$ - and  $\beta$ -naphthaldehydes are good substrates in which can be converted with yields of 62% and 84%, respectively. The more sterically-demanding 9-anthraldehyde is hardly cyanosilylated. These shape specificities may be ascribed to the size of the cavity of the network material. In 2004, the same research group has synthesized {Cd(4,4'-bpy)<sub>2</sub>(H<sub>2</sub>O)<sub>2</sub>(NO<sub>3</sub>)<sub>2</sub>·4H<sub>2</sub>O}<sub>n</sub>,<sup>33</sup> a square network to investigate mechanistic aspects of this cyanosilylation reaction. Thus, the catalytic study has been extended to the cyanosilylation of imines to gain some mechanistic insights in the heterogeneous catalysis mediated by the coordination compound. It has been found that the substrate accommodated in the square cavity, can easily coordinate to the Cd<sup>2+</sup> center of the next network layer. It has therefore been suggested that the active sites exist mainly around the surface of the solid. They noted that, given a surface-promoted reaction, the catalytic activity of this porous polymer is remarkably high. Moreover, the Cd(II) center is more cationic and stronger Lewis acidic than mononuclear Cd(NO<sub>3</sub>)<sub>2</sub>·4H<sub>2</sub>O. Size-selective reactions involving a MOF catalyst have been recently reported for Mn<sub>3</sub>[(Mn<sub>4</sub>Cl)<sub>3</sub>(BTT)<sub>8</sub>(CH<sub>3</sub>OH)<sub>10</sub>]<sub>2</sub> (H<sub>3</sub>BTT=1,3,5-benzenetris tetrazol-5-yl),<sup>29</sup> wherein Mn<sup>2+</sup> ions exposed on the surface of the framework might serve as potential Lewis acidic sites. Indeed, this MOF catalyzes the cyanosilylation

of aromatic aldehydes and ketones, as well as the Mukaiyama-aldol reaction. In each case, a pronounced size-selectivity effect consistent with the pore dimensions is observed.

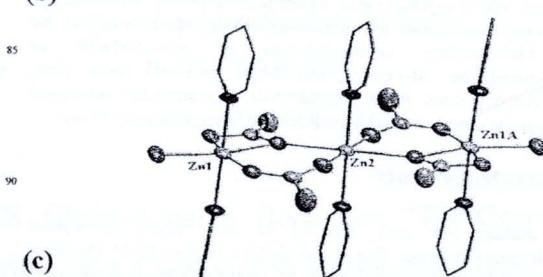

### Heterogeneity

The heterogeneity of the catalytic reaction has been probed for the cyanosilylation of acetaldehyde in THF, mediated by compound **1**. Thus, the catalyst (compound **1**) has been filtered out after a reaction time of 5 h, corresponding to an acetaldehyde conversion of 24% (Fig. 7). The filtrate has been stirred for 24 h and no further conversion of the substrate is observed (about 25% conversion; Fig. 7). This result clearly demonstrates that no homogeneous catalytic species is present in solution. Next, the filtrate has been divided into two equal parts. The first part has been stirred with fresh catalyst **1** while the other one has been stirred without catalyst. In the filtrate without catalyst, the reaction does not proceed further, whereas in the catalyst-containing suspension, the conversion of the substrate is

(c)

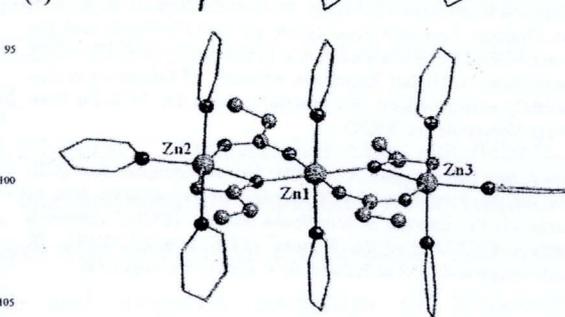

Fig. 6. Representation of the asymmetric units of (a) **1**, (b) **2** and (c) **3**, showing the atom-labeling schemes for the zinc(II) ions. The perchlorate anions and the lattice water molecules are not shown for clarity.

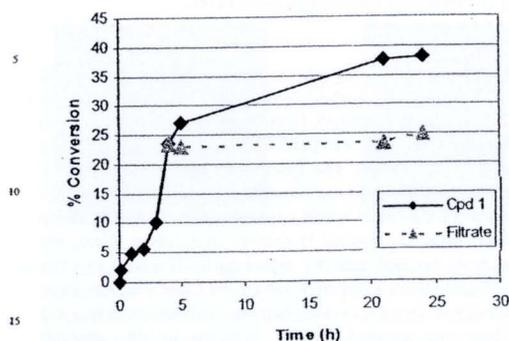

Fig. 7. Cyanosilylation of acetaldehyde in THF catalysed by 1

observed, reaching 38% after 24 h (Fig. 7). Thus, the catalytic activity of Zn(II)-4,4'-bpy-carboxylate originates from the presence of the solid catalyst and is not due to molecular species that dissolve into the solution. Furthermore, the isolated catalyst (by filtration after a reaction time of 24 h) can be reused without apparent loss of activity.

## Conclusions

In summary, the present study, describes the host-guest and catalytic properties of three coordination polymers, belonging to the second generation of porous coordination compounds. The removal/reintroduction of water guest molecules is accompanied by a crystalline-to-crystalline structural transformation of the material, which exhibits rigid vacant host channels. Interestingly, the Zn(II) compounds are effective heterogeneous catalysts for the high-yielding cyanosilylation of acetaldehyde in dichloromethane. Moreover, the MOF catalysts show size-selective behaviors since acetaldehyde is efficiently converted whereas the conversion of benzaldehyde is significantly lower.

## Acknowledgements

The authors are very grateful to the Higher Education Development Projects: The Royal Golden Jubilee Ph.D. Program (RGJ) and Khon Kean University for a research grant. Support of The Thailand Research Fund (grant no BRG5280012) and the Center of Excellence for Innovation in Chemistry (PERCH-CIC), Commission on Higher Education, Ministry of Education is also gratefully acknowledged. We gratefully thank Dr. W.T. Fu from Leiden University for XRPD.
