The purposes of this quasi-experimental reseach were to compare child development promotion knowledge and behavior of the labour working mothers. Research sample consisted of 60 the labour working mothers who had the first 2-3 year old child and were assigned into an experimental group and a control group. The experimental group was given home health education. Research instruments, developed by the researcher were a lesson plan of child developmental promotion, a handbook of child developmental promotion, a knowledge test, a mother's behavior questionnaire and the Thai Developmental Screening Test (TDST) by Laksanavicharn and et.al. .

Analysis of the data was done by using SPSS/PC and the major results were as follows :

1. The mean knowledge and behavior scores of mothers after receiving home health education in experimental group were statiscally significant higher than prior home health education, at the .05 level.
2. The mean knowledge and behavior scores of mothers after the experiment, in control group were not significant different compare to before experiment.
3. The mean knowledge and behavior scores of mothers after the experiment in experimental group were statistically significant higher than that of the control group, at the .05 level.
