#### ABSTRACT

The objective of this research is to study the effectiveness of health education on AIDS through group discussion among 15-25 year old male students of Charunsanitwong Commercial school, in Bangkok, Thailand.

This is a two group quasi - experimental design, one group of 75 students were given the health education and another group of 75 students in Rajadomern Commercial School without health education. Both were given the pre and the post tests using self administered questionnaire.

The result of the post - test showed that there was positive difference in the level of knowledge, belief and attitude and in the intention among the experimental group who were given the health education.

The control group which did not have health education also manifested increase in the level of knowledge and in the intention in the post - test but not as much as that of the experimental group. This increase can be attributed to their exposure to the same questionnaire in the pre - test. However their level of belief and attitude decreased.
