

The research result by the study data analysis through SPSS/PC plus software package revealed that the village headmen's leadership quality, training experience, water supply promotion experience and educational level have significant association with their knowledge and attitude toward water supply. Number of households of the villages has association with the village headmen's attitude toward water supply. However, the village headmen's age, economical status and the villages' population were not related to their knowledge and attitude toward water supply. Further study is needed to determine the relationships among the village specific environment of leadership with Primary Health Care programs.
