## **ACKNOWLEDGEMENTS**

I would like to express my sincere gratitude and deep appreciation to Prof. Vithaya Meevootisom, my major advisor for invaluable guidance, supervision and encouragement throughout this study. Equally, I am grateful attitude to Assist. Prof. Suthep Wiyakrutta, my co-advisor, for his guidance, comments, suggestions and discussion.

I also would like to thank Dr. Michael J. McLeish and Prof. George L. Kenyon (University of Michigan, USA) for their creative guidance, continuous discussion and especially for their support and kindness while I was doing a part of the thesis in USA.

I also wish to sincerely thank Assist. Prof. Theerasak Rojanarata and Duangnate Isarangkul Na Ayudhaya for their endless kindness and helpful guidance. My thankfulness is to Dr. Poramaet Laowanapiban, all of B600 and B601 members and other people who have not been mentioned here for their kind help and friendship during my study.

Of the most importance, I greatly appreciate my mother, my sister and my brother for their loves, understanding, support and encouragement in every way possible to enable me to succeed in my education.

Lastly, I am particularly indebted to Institutional Strengthening Programme of Faculty of Science, Mahidol University (2000-2002), Thesis Scholarship from the Commission on Higher Education and Faculty of Graduate Studies, Mahidol University (2004) and the Royal Golden Jubilee Ph.D. Programme, Thailand Research Fund (2005-2007) that enabled me to have a wonderful opportunity for my study.

**ABSTRACT**

In this study, the role in D-phenylglycine degradation, gene cloning, expression, purification and characterization of a benzoylformate decarboxylase from *Pseudomonas stutzeri* ST-201 (*PsBFDC*) were investigated. Following induction with D-phenylglycine, both D-phenylglycine aminotransferase and then BFDC activity were detected in cultures of *P. stutzeri* ST-201. Induction with benzoylformate, on the other hand, induced only BFDC activity. Sequential expression of the enzymes demonstrated the role of BFDC in the pathway in a step following D-phenylglycine degradation. Purification and N-terminal sequencing of *PsBFDC* enabled the design of probes for hybridization in gene cloning. Sequencing of one genomic DNA restriction fragment revealed an open reading frame designated as *dpgB* which encoded *PsBFDC*. Sequence alignment also suggested that the gene encoded a thiamin-diphosphate dependent enzyme. A *dpgB* gene which consisted of 1,581 bps of nucleotides and encoded a polypeptide of 526 amino acids was expressed with pET17b in *Escherichia coli* BL21 (DE3) and purified to homogeneity in a series of steps including ammonium sulfate fractionation, followed by Phenyl Sepharose FF hydrophobic interaction chromatography, ultrafiltration and Q-Sepharose FF anion-exchange chromatography with specific activity of 243 U mg<sup>-1</sup>. Molecular weight ( $M_r$ ) of the native *PsBFDC* was estimated to be 224 kDa whereas  $M_r$  of the enzyme subunit was approximately 56 kDa. This indicated that the enzyme associated as a homotetramer. The isoelectric point (pI) of the enzyme was 5.2. The temperature and pH for maximal activity were 35-50 °C and 6.0, respectively.  $K_m$  value for benzoylformate was 0.69 mM and  $k_{cat}$  value was 222 s<sup>-1</sup>. In addition to *PsBFDC*, in this study a gene encoding a NAD<sup>+</sup>/NADP<sup>+</sup>-dependent benzaldehyde dehydrogenase (*PsBADH*) denoted *dpgC* was cloned and expressed. Both *PsBFDC* and *PsBADH* had high sequence identities (both greater than 85%) and kinetic properties similar to those of the homologous enzymes in the mandelate pathway of *P. putida* ATCC 12633. However, *P. stutzeri* ST-201 was unable to grow on either isomer of mandelate, and sequencing indicated that the *dpgB* gene did not form part of an operon. Thus it appears that the two enzymes form part of a D-phenylglycine, rather than mandelate, degradation pathway.

### บทคัดย่อ

การศึกษานี้รายงานบทบาทของเอนไซม์เบนโซอิลฟอร์มเมต ดีคาร์บอกซิเลส (*PsBFDC*) ใน *Pseudomonas stutzeri* ST-201 ในการย่อยสลายดี-ฟีนิลกลัยซีน รวมถึงการโคลนยีน การทำให้ยีนแสดงออก การทำเอนไซม์ให้บริสุทธิ์ และการศึกษาคุณสมบัติของเอนไซม์ โดยพบว่า *P. stutzeri* ST-201 สร้างเอนไซม์ดี-ฟีนิลกลัยซีน อะมิโนทรานสเฟอเรส และตามด้วย *PsBFDC* ในเวลาต่อมาเมื่อถูกชักนำด้วยดี-ฟีนิลกลัยซีน แต่แบคทีเรียชนิดนี้สร้างเพียง *PsBFDC* เท่านั้นเมื่อถูกชักนำด้วยเบนโซอิลฟอร์มเมต ผลที่ได้แสดงให้เห็นว่า *PsBFDC* มีบทบาทในขั้นตอนต่อจากการย่อยสลายดี-ฟีนิลกลัยซีน เมื่อแยก *PsBFDC* จาก *P. stutzeri* ST-201 และทำให้บริสุทธิ์แล้วนำไปหาลำดับของกรดอะมิโนด้านปลาย N เพื่อใช้ออกแบบ probe สำหรับทำ hybridization ในการโคลนยีน ได้ยีนดีเอ็นเอที่มี open reading frame ให้ชื่อว่า *dpgB* เป็นรหัสสำหรับเอนไซม์ *PsBFDC* ซึ่งเมื่อทำ sequence alignment พบว่ามีความคล้ายคลึงกับยีนในกลุ่ม thiamin-diphosphate dependent enzymes ยีน *dpgB* นี้ประกอบด้วยนิวคลีโอไทด์ 1,581 คู่เบส และสร้างโพลีเปปไทด์ที่ประกอบด้วยกรดอะมิโน 526 ตัว เมื่อนำยีนนี้ซึ่งโคลนอยู่ในเวกเตอร์ pET17b ไปทำให้เกิดแสดงออกใน *Escherichia coli* BL21 (DE3) แล้วนำเอนไซม์ที่ได้ไปผ่านกระบวนการทำให้บริสุทธิ์ซึ่งประกอบด้วยการตกตะกอนโปรตีนด้วย ammonium sulfate ต่อด้วย Phenyl Sepharose FF hydrophobic interaction chromatography, ultrafiltration และ Q-Sepharose FF anion-exchange chromatography ในที่สุดได้เอนไซม์บริสุทธิ์ที่มี specific activity เท่ากับ  $243 \text{ U mg}^{-1}$  น้ำหนักโมเลกุลของ native *PsBFDC* มีค่าประมาณ 224 kDa และหน่วยย่อยของเอนไซม์มีน้ำหนัก 56 kDa นั่นคือเอนไซม์ชนิดนี้ประกอบด้วยหน่วยย่อยที่เหมือนกัน 4 หน่วย เอนไซม์มี isoelectric point (pI) ที่ 5.2 ทำงานได้ดีที่สุดในช่วง  $35\text{-}50^\circ\text{C}$  pH 6.0 ค่า  $K_m$  สำหรับเบนโซอิลฟอร์มเมตคือ 0.69 mM และค่า  $k_{cat}$  คือ  $222 \text{ s}^{-1}$  การศึกษาค้นคว้านี้ยังสามารถโคลนยีนสำหรับ  $\text{NAD}^+/\text{NADP}^+$ -dependent benzaldehyde dehydrogenase จาก *P. stutzeri* ST-201 (*PsBADH*) ซึ่งให้ชื่อว่ายีน *dpgC* และทำให้เกิดการแสดงออกของยีนได้ เมื่อเปรียบเทียบกับเอนไซม์ในวิถีการย่อยสลายแมนดีเลต พบว่าทั้งเอนไซม์ *PsBFDC* และ *PsBADH* มีความคล้ายคลึงกันในแง่ลำดับกรดอะมิโน (มากกว่า 85% identity) และคุณสมบัติทางจลนศาสตร์กับ homologous enzymes ที่พบใน *P. putida* ATCC 12633 อย่างไรก็ตามเนื่องจาก *P. stutzeri* ST-201 ไม่สามารถเจริญเติบโตได้โดยใช้แมนดีเลต อีกทั้งยีน *dpgB* ก็มีได้เป็นส่วนหนึ่งของโอเปอรอน ดังนั้นเอนไซม์ *PsBFDC* และ *PsBADH* ใน *P. stutzeri* ST-201 น่าจะทำหน้าที่ในวิถีการย่อยสลายดี-ฟีนิลกลัยซีน แทนที่จะเป็นวิถีการย่อยสลายแมนดีเลต

## CHAPTER 1

### INTRODUCTION

#### 1. Introduction

Benzoylformate decarboxylase (BFDC; EC 4.1.1.7) is a thiamin diphosphate (ThDP)-dependent enzyme that catalyzes both non-oxidative decarboxylation of benzoylformate forming benzaldehyde and carbon dioxide (1) (Figure 1A) and carboligation (C-C bond formation) enabling the conversion of aldehydes to chiral 2-hydroxy ketones, which are versatile building blocks for a variety of different fine chemicals (Figure 1B).

**Figure 1.** Decarboxylation (A) and carboligation (B) reactions catalyzed by BFDC.

BFDC was initially identified as one of the enzymes in the mandelate pathway, which enables bacteria to utilize mandelate as a sole carbon source by converting it to benzoic acid, which is then metabolized via the  $\beta$ -ketoacid pathway and the citric acid cycle. In this pathway, benzoylformate is formed via the oxidation of *S*-mandelate (Figure 2) (2-4). To date, the enzyme has been found in *Pseudomonas*, *Acinetobacter*

species (5, 6), and *Neurospora crassa* (7), with the most detailed studies being carried out on the BFDC from *Pseudomonas putida* ATCC 12633 (*Pp*BFDC). These include enzyme purification and characterization (3, 4), gene cloning (8), kinetic and mechanistic studies (9-11), and X-ray crystallography (12, 13). Over the past few years *Pp*BFDC has become increasingly useful for the synthesis of enantiomerically pure pharmaceutical and chemical compounds (14-16). Consequently, there is a commercial interest in identifying BFDCs with an expanded substrate range whether by protein engineering (17-19) or from alternative sources such as metagenomic libraries (20).

Benzoylformate was reported as a product of the reaction catalyzed by D-phenylglycine aminotransferase (D-PhgAT) in *P. stutzeri* ST-201, a soil bacterium isolated in Thailand (21). Later, the gene encoding D-phgAT (*dpgA*) was cloned and expressed in *E. coli*. In those studies, *P. stutzeri* ST-201 had not been reported to possess BFDC, however, it had been shown to release both benzoylformate and benzoate into the culture medium during the early stages of D-phenylglycine degradation (21). Therefore it was reasonable to hypothesize that this strain probably produce not only BFDC, but also another related enzyme namely benzaldehyde dehydrogenase (BADH) for subsequent metabolism of benzoylformate and benzaldehyde, respectively. Here, we successfully prove the presence of BFDC in *P. stutzeri* ST-201 (*Ps*BFDC) and the role of *Ps*BFDC in D-phenylglycine degradation. Not only the gene encoding *Ps*BFDC (*dpgB*) but also the gene for *Ps*BADH (*dpgC*) have been cloned and expressed in *E. coli* and their gene products have been characterized. Moreover, we suggest that both enzymes form part of a catabolic pathway, which was termed the D-phenylglycine degradation pathway (Figure 2).

**Figure 2.** The mandelate pathway in *P. putida* ATCC 12633 and the proposed pathway for D-phenylglycine degradation in *P. stutzeri* ST-201.

## 2. Objectives

1. To study the role of *Ps*BFDC in D-phenylglycine degradation pathway of *P. stutzeri* ST-201.
2. To isolate and purify *Ps*BFDC from *P. stutzeri* ST-201.
3. To clone the gene encoding *Ps*BFDC (*dpgB*) and express in *E.coli*.
4. To characterize recombinant *Ps*BFDC.
5. To express and characterize histidine-tagged *Ps*BFDC.
6. To clone the gene encoding *Ps*BADH (*dpgC*), express and characterize histidine-tagged *Ps*BADH.

## CHAPTER 2

### LITERATURE REVIEW

#### 1. Thiamin diphosphate (ThDP)-dependent enzymes

##### 1.1 Thiamin diphosphate

Thiamin diphosphate serves as a versatile cofactor in a number of enzymatic processes found in almost all major metabolic pathways. ThDP (Figure 3) consists of a pyrimidine ring, a thiazolium ring and a diphosphate group.

**Figure 3.** Chemical structure of thiamin diphosphate.

##### 1.2 Thiamin diphosphate-dependent enzymes

ThDP-dependent enzymes include those having the potential reactions of both breaking and forming C-C bonds (22-24). The spectrum of reactions catalyzed by ThDP-enzymes encompasses non-oxidative decarboxylation of  $\alpha$ -keto acid ( $\alpha$ -keto acid decarboxylases), oxidative decarboxylation of  $\alpha$ -keto acid (pyruvate oxidase), carboligation [transketolases (TKT),  $\alpha$ -keto acid decarboxylases, acetoacetate syntase] as well as the cleavage of C-C bonds (TKT, benzaldehyde lyase).

A common feature of ThDP-dependent enzymes is the formation of a ThDP-bound carbanionic intermediate upon cleavage of a C-C bond (e.g. decarboxylation). The resulting intermediate was named “active aldehyde” (22).

The enzymes of this family differ widely, however, with regard to the fate of the ThDP-bound active aldehyde.  $\alpha$ -Keto acid decarboxylases allow protonation of the intermediate, and their main products are the respective aldehydes.

However, these enzymes are also capable of performing an acyloin-type condensation reaction leading to chiral  $\alpha$ -hydroxy ketones (Figure 4). This makes them interesting as catalysts for biotransformations.

**Figure 4.** Reaction pathway of enzymatic  $\alpha$ -keto acid decarboxylases and formation of  $\alpha$ -hydroxy ketones by pyruvate decarboxylase (PDC) and benzoylformate decarboxylase (BFDC). (25)

Chiral  $\alpha$ -hydroxy ketones are versatile building blocks for the organic and pharmaceutical chemistry, e.g. for the synthesis of vitamin E and antifungals. Another well known example is the synthesis of (*R*)-phenylacetyl carbinol (PAC). For many decades, this pre-step for the synthesis of (1*R*,2*S*)-ephedrine has been obtained by biotransformation of benzaldehyde using a fermenting yeast. The optimization of this process is still a matter of research (Figure 5).

**Figure 5.** Synthesis of (1*R*,2*S*)-ephedrine. (25)

### 1.3 $\alpha$ -Keto acid decarboxylases

Among the ThDP-dependent  $\alpha$ -keto acid decarboxylases, which catalyze the decarboxylation of  $\alpha$ -keto acids as the main reaction, pyruvate decarboxylases (PDC), benzoylformate decarboxylases (BFDC), phenylpyruvate decarboxylases (PhePDC) and indole-3-pyruvate decarboxylases (InPDC) are the examples shown in Table 1. Whereas the formation of C-C bonds has been observed as a side-reaction of some of these enzymes, other  $\alpha$ -keto acid decarboxylases like acetolactate synthase (EC 4.1.3.18) or  $\alpha$ -keto glutarate synthase (EC 4.1.1.71) have both decarboxylation and carboligation in their main reaction paths.

**Table 1.** ThDP-dependent  $\alpha$ -keto acid decarboxylases.

### 1.4 Mechanism of decarboxylation and carboligation

The capability of ThDP to catalyze the decarboxylation of  $\alpha$ -keto acids depends mainly on two properties of the thiazolium ring of ThDP: (a) its capacity to ionize to form an anion (ylide) and attack the  $\alpha$ -carbonyl group of  $\alpha$ -keto acids, and (b) its ability to stabilize the negative charge upon cleavage of the carbon dioxide. Different steps, which are relevant for thiamin-catalyzed decarboxylation and the formation of  $\alpha$ -hydroxy ketones, are summarized in Figure 4.

The reaction cycle is started with activation of ThDP by the enzyme. This initial deprotonation step has recently been elucidated for PDCs and transketolase by Kern et al. (26). Subsequently, the negatively charged C2-ThDP, ThDP-carbanion (ylide) performs a nucleophilic attack on the  $\alpha$ -carbonyl group of the  $\alpha$ -keto acid. The resulting double negatively charged species is stabilized by proton transfer to the

former carbonyl group to give first tetrahedral complex. The decarboxylation of this complex results in the formation of an  $\alpha$ -carbanion-enamine. This step has been intensively studied with PDC from yeast using conjugated  $\alpha$ -keto acids with strong electron-withdrawing substituents on the phenyl ring. PDC converts such compounds to an  $\alpha$ -carbanion-enamine that is a visible chromophore with a discrete life-time. A series of [*p*-(halomethyl)]benzoylformates have been investigated as substrates for BFDC. These analogues vary from acting as normal substrates to acting as competitive inhibitors (27, 28).

The carbanionic intermediate, carbanion-enamine is probably present in the mechanism of all ThDP-dependent enzymes, which decarboxylate  $\alpha$ -keto acids as the first step. The main reaction path of  $\alpha$ -keto acid decarboxylases is the generation of the respective aldehydes.

Alternatively, the formation of  $\alpha$ -hydroxy ketones has been described for PDCs and BFDC. The last step of the reaction cycle is reversible in PDC. Thus carbanion-enamine may also be generated by addition of an aldehyde to give a second tetrahedral complex and with subsequent deprotonation. The latter reaction path allows the formation of  $\alpha$ -hydroxy ketones from aldehydes as precursors.

## 2. Benzoylformate decarboxylases (BFDC)

Benzoylformate decarboxylase (BFDC) (E.C. 4.1.1.7) catalyzes the formation of benzaldehyde from benzoylformate by decarboxylation, and carboligation, side reaction. BFDC has been found in *Pseudomonas putida* ATCC 12633 (*Pp*BFDC) (3, 4), *Pseudomonas aeruginosa* (*Pa*BFDC) (29), *Acinetobacter calcoaceticus* (*Ac*BFDC) (5) and *Neurospora crassa* (*Nc*BFDC) (7) (Table 1). The properties of BFDCs are shown in Table 2.

**Table 2.** Enzyme properties of BFDCs.

### 3. Benzoylformate decarboxylase from *Pseudomonas putida* ATCC 12633 (*Pp*BFDC)

#### 3.1 As a component of mandelate pathway

*Pp*BFDC is a component of the mandelate pathway, which allows *P. putida* to utilize *R*-mandelic acid as a sole carbon source by converting it finally to benzoic acid, which is then metabolized further via the  $\beta$ -ketoacid pathway to the tricarboxylic acid cycle intermediates succinyl-coenzyme A (CoA) and acetyl-CoA (Figure 6).

**Figure 6.** Mandelate and  $\beta$ -ketoadipate pathways in *P. putida*. The mandelate pathway in *Pseudomonas putida* ATCC 12633 is shown in dark gray, and the conversion of benzoylformate to benzaldehyde by a benzoylformate decarboxylase (MdlC or BFDC) is highlighted. The  $\beta$ -ketoadipate pathway (gray) also exists in the majority of all pseudomonads. Additionally, *P. putida* KT2440 and *P. putida* DSM50198 possess a benzaldehyde dehydrogenase. The metabolization of succinyl-CoA and acetyl-CoA via the tricarboxylic acid cycle is shown in light gray. MdlA, mandelate racemase; MdlB, S-mandelate dehydrogenase; MdlD (BADH),  $\text{NAD}^+$ - and  $\text{NADP}^+$ -benzaldehyde dehydrogenases; BenABC, benzoate dioxygenase; BenD, 2-hydroxy-1,2-dihydroxybenzoate dehydrogenase; CatA, catechol-1,2-dioxygenase; CatB, cis,cis-muconate lactonizing enzyme (cycloisomerase); CatC, muconolactone isomerase; PcaD,  $\beta$ -ketoadipate enolactone hydrolase I; PcaIJ,  $\beta$ -ketoadipate succinyl-CoA transferase subunit; PcaF,  $\beta$ -ketoadipyl CoA thiolase; TCA, tricarboxylic acid. (20)

Only *Pp*BFDC has been cloned so far (8), and its crystal structure was solved in the absence (13) and the presence (11) of mandelic acid as an inhibitor. The X-ray data suggested that the enzyme acted as a tetrameric enzyme of 240 kDa and the active site residues of *Pp*BFDC were elucidated by using site-directed mutants (11, 19) and directed evolution studies (17, 19).

### **3.2 Organization of genes involved in the mandelate pathway**

Genetic experiments indicated that the genes for the mandelate pathway were all closely clustered on the chromosome (30, 31) and subsequently, it was reported that the mandelate pathway genes for *P. putida* ATCC 12633 resided on a single 10.5-kb restriction fragment as shown in Figure 7 (8). Sequencing of part of that fragment showed that three of the genes - those encoding mandelate racemase (*mdlA*), *S*-mandelate dehydrogenase (*mdlB*), and benzoylformate decarboxylase (*mdlC*) were arranged in an operon (8, 32). Furthermore, it appeared that the *mdlD* gene encoding for the NAD(P)<sup>+</sup>-dependent benzaldehyde dehydrogenases (BADH) located upstream of the *mdlC* gene (33) and was transcribed independently. Currently, the *mdlY* gene has been cloned and expressed in *E. coli*, the gene product was purified and identified as a mandelamide hydrolase (MAH) (34). The *mdlX* encoded for a transcriptional regulatory protein which was revealed by the analysis of the deduced amino acid sequence from the open reading frame.

**Figure 7.** Schematic representation of the 10.5-kb *EcoRI* restriction fragment carrying genes of the mandelate pathway of *P. putida* ATCC 12633. The arrows show the position and orientation of the genes, and relevant restriction sites are indicated: E, *EcoRI*; H, *HindIII*; and X, *XbaI*. (34)

### 3.3 Structural and kinetic analysis of catalysis in decarboxylation by *Pp*BFDC (11)

The mechanism of non-oxidative decarboxylation suggested for ThDP-dependent catalysis by *Pp*BFDC binding with *R*-mandelate, a competitive inhibitor, similar to that of other related enzymes, is shown in Figure 8. In the initial step, the C4' imino group of ThDP abstracts a proton from the C2 atom of the thiazolium ring, resulting in the formation of an ylide. The ylide attacks the carbonyl of the substrate to form the first tetrahedral intermediate, 2- $\alpha$ -mandelyl-ThDP. Decarboxylation of 2- $\alpha$ -mandelyl-ThDP results in the enamine intermediate. Protonation of the enamine provides a second tetrahedral intermediate, 2- $\alpha$ -hydroxybenzyl-ThDP. Finally, benzaldehyde is eliminated with the assistance of an enzymic base.

**Figure 8.** Postulated chemical mechanism for the *Pp*BFDC-catalyzed decarboxylation of benzoylformate. (11)

A structure of this enzyme binding *R*-mandelate, a competitive inhibitor, suggests that at least two hydrogen bonds are formed between the substrate, benzoylformate, and the active site side chains. The first one is between the carboxylate group of benzoylformate and the hydroxyl group of S26, and the second one is between carbonyl group of the substrate and an imidazole nitrogen of H70. Both steady state kinetic studies and stopped-flow experiments suggest the following roles for residues in the active site. The residue H70 is important for the protonation of the 2- $\alpha$ -mandelyl-ThDP intermediate, thereby assisting in decarboxylation, and for the deprotonation of the 2- $\alpha$ -hydroxybenzyl-ThDP intermediate, aiding product release. The residue H281 is involved in protonation of the enamine. Surprisingly, the residue S26 appears to be involved not only in substrate binding but also in other steps of the reaction.

### 3.4 Carboligation mediated by *Pp*BFDC

The formation of  $\alpha$ -hydroxyketones by *Pp*BFDC was first described by Wilcocks et al. (35) using whole cells and cell extracts of *P. putida*, which formed *S*-2-hydroxypropiophenone (2-HPP) from benzoylformate and acetaldehyde as shown in Figure 9. The enantiomeric excess of 2-HPP was determined by  $^1\text{H-NMR}$  spectroscopy and was found to be 91 - 92%.

Factors affecting 2-HPP formation by *Pp*BFDC were investigated by Wilcocks and Ward (36) and were found to be a broad pH optimum (pH 5-8) and temperature optimum (20-40°C). Recently, *Pp*BFDC did also produce *R*-benzoin with high enantiomeric excess.

**Figure 9.** Reaction products of the biotransformation of benzoylformate and acetaldehyde with *Pp*BFDC. (25)

### 3.5 Substrate specificity of *Pp*BFDC

The substrate spectrum of *Pp*BFDC is limited to aromatic substrates. *Pp*BFDC requires substrates with an aromatic ring directly connected to the  $\alpha$ -carbonyl group. Only benzoylformate or *para*-substituted benzoylformate (methylbenzoylformate, fluoromethylbenzoylformate, hydroxymethylbenzoylformate) have been shown as substrates, whereas pyruvate,  $\alpha$ -ketobutyrate or  $\alpha$ -ketoglutarate are not substrates (27). Recently, expanded substrate range of *Pp*BFDC was also studied (19).

### 3.6 Crystal structure of *Pp*BFDC

#### 3.6.1 Description of the overall structure

*Pp*BFDC is composed of three domains, each is built around a central  $\beta$ -sheet. The  $\alpha$ - and  $\gamma$ - domains are topologically equivalent, while the  $\beta$ -domain has a slightly different fold. Residues that make contact with the cofactor ThDP are located at the C-terminal ends of strands in the  $\alpha$ - and  $\gamma$ -domain sheets. A detailed schematic diagram of the structure of *Pp*BFDC is presented in Figure 10, and a ribbon diagram of the monomer is shown in Figure 11.

Figure 10. Schematic diagram of the *Pp*BFDC structure. Arrows indicate  $\beta$ -strands; rectangles indicate helices. Beginning and ending residues for each element of secondary structure are indicated. Major contacts (between monomers in the dimer and tetramer and crystal contacts) are indicated. Contacts with the cofactor ThDP are indicated in bold. Helices in white are in front of the  $\beta$ -sheets; shaded helices are behind the sheet. (13)

**Figure 11.** Ribbon diagram of the structure of a monomer of *PpBFDC*. This stereo diagram is the same orientation as the schematic diagram in figure 10, with the  $\alpha$ -domain on top, the  $\beta$ -domain at lower left, and the  $\gamma$ -domain at lower right. (13)

The architecture of *PpBFDC* is shared by the other enzymes of known structure that utilize the cofactor ThDP: pyruvate decarboxylase, pyruvate oxidase, and transketolase. Consequently, the structure of *PpBFDC* was able to superimpose on each of the other three ThDP-containing structures.

### 3.6.2 Quaternary structure

The native enzymes *PpBFDC*, PDC, and pyruvate oxidase exist as tetramers, while transketolase as a dimer. ThDP is bound at a dimer interface in *PpBFDC*, as with the other three enzymes. The binding site is formed by the  $\alpha$ -domain of one monomer and the  $\gamma$ -domain of the other. Thus, it is useful to consider the *PpBFDC* tetramer as a dimer of dimers as shown in Figure 12. The two dimers that make up the *PpBFDC* tetramer are much more intimately associated than those that make up the PDC tetramer; in this sense, *PpBFDC* is much more similar to pyruvate oxidase.

**Figure 12.** Ribbon diagram of the structure of a tetramer of *PpBFDC*. Two active sites are at the interface between the red and purple monomers, and two are at the interface between the yellow and green monomers. The cofactor ThDP and its associated metal ion are shown as a ball-and-stick representation. Domains are labeled in the red monomer. (13)

### 3.6.3 Cofactor properties of *PpBFDC*

In *PpBFDC*, the ThDP and  $Mg^{2+}$  cofactors are located in the interface between two identical subunits. Each tetramer contains four ThDP molecules and four  $Mg^{2+}$  ions. Moreover, two additional metal ions are present, a  $Mg^{2+}$  which is located in the interface between two subunits and a  $Ca^{2+}$  ion at a crystal contact. The cofactors are buried deep in the enzyme.

The binding properties of the cofactors and the possible catalytic role of the residues located in the active center of the enzyme *PpBFDC* are presented in Table 3. The metal ion Mg(II) is octahedrally coordinated with the carboxyl/carbonyl oxygen atoms of the conserved residues Asp, Asn, Gly, Gln and the diphosphate group of ThDP. Other conserved residues (Table 3) interact through hydrogen bonds with N(1') and N(4' $\alpha$ )H<sub>2</sub> of the pyrimidine ring and the N(3) of the thiazole.

**Table 3.** Cofactor properties and temporary groups of residues involved in catalysis of the enzyme *PpBFDC* (37) as revealed by crystal structure analysis (13) and site directed mutagenesis studies (11).

#### 4. Benzaldehyde dehydrogenase (BADH)

Benzaldehyde dehydrogenase catalyzes the generally irreversible conversion of benzaldehyde to benzoate by oxidation as shown in Figure 13. BADH has been found in *Pseudomonas putida* ATCC 12633 (*PpBADH*) (34). Additionally, chromosomes of *P. putida* KT 2440 and *P. putida* DSM 50198 possess DNA sequences of putative BADH (20).

**Figure 13.** Reaction catalyzed by benzaldehyde dehydrogenase (BADH).

## 5. Benzaldehyde dehydrogenase from *Pseudomonas putida* ATCC 12633 (*Pp*BADH)

### 5.1 As a component of mandelate pathway

*Pp*BADH is a component of the mandelate pathway, which allows *P. putida* to utilize *R*-mandelic acid as a sole carbon source by converting benzaldehyde to benzoic acid, which is then metabolized by the  $\beta$ -ketoacid pathway to the tricarboxylic acid cycle intermediates, succinyl-coenzyme A (CoA) and acetyl-CoA (Figure 6). *Pp*BADH is an NAD(P)<sup>+</sup>-dependent enzyme having the molecular weight, as determined by electrospray mass spectroscopy, of 47,425 kDa which is consistent with the 47,431 kDa deduced from the amino acid sequence (34). *Pp*BADH is transcribed from the *mdlD* gene which consists of 1,311 base pairs. The enzyme is a homodimeric enzyme. It exhibits greater affinity for NAD<sup>+</sup> than NADP<sup>+</sup> and it is classified as a class 3 aldehyde dehydrogenase (38). It is similar to the rat class 3 aldehyde dehydrogenase, but unlike the *P. aeruginosa* enzymes betaine aldehyde dehydrogenase and glucose-6-phosphate dehydrogenase, in that both of which have greater affinity for NADP<sup>+</sup>.

Aldehyde dehydrogenases are classified into at least 13 distinct families. Most are specific for NAD<sup>+</sup> and a few are specific for NADP<sup>+</sup>. The class 3 aldehyde dehydrogenases are characterized by an ability to use NAD<sup>+</sup> or NADP<sup>+</sup>.

### 5.2 Kinetic parameters for *Pp*BADH

Kinetic parameters for *Pp*BADH are shown in Table 4.

**Table 4.** Kinetic parameters for *Pp*BADH. (34)

Cofactor	$K_m$ for benzaldehyde ( $\mu\text{M}$ )	$k_{\text{cat}}$ ( $\text{min}^{-1}$ )	$k_{\text{cat}}/K_m$ ( $\text{min}^{-1} \text{M}^{-1}$ )
NAD <sup>+</sup>	$63.4 \pm 1.5$	$(8.24 \pm 0.32) \times 10^3$	$1.3 \times 10^8$
NADP <sup>+</sup>	$39.9 \pm 4.4$	$(2.55 \pm 0.10) \times 10^3$	$6.39 \times 10^7$

## 6. *Pseudomonas stutzeri* ST-201

### 6.1 Definition of species (39)

*Pseudomonas stutzeri* is a member of the genus *Pseudomonas* sensu stricto. It is in group I of Palleroni's DNA-rRNA homology group within the phylum *Proteobacteria*. *P. stutzeri* is now recognized as those belonging to the class *Gammaproteobacteria*. Phylogenetic studies of *P. stutzeri* strains' 16S rRNA sequences and other phylogenetic markers demonstrate that they belong to the same branch, together with related species within the genus, such as *P. mendocina*, *P. alcaligenes*, *P. pseudoalcaligenes*, and *P. balearica*.

Typically, cells are rod shaped, 1 to 3  $\mu\text{m}$  in length and 0.5  $\mu\text{m}$  in width, and have a single polar flagellum. Under certain conditions, one or two lateral flagella may be produced. Phenotypic traits of the genus include a negative Gram stain, positive catalase and oxidase tests, and a strictly respiratory metabolism. In addition, *P. stutzeri* strains are defined as denitrifiers. They can grow on starch and maltose and have a negative reaction in arginine dihydrolase and glycogen hydrolysis tests.

The G+C content of their genomic DNA lies between 60 and 66 mol %. DNA-DNA hybridizations enable at least 17 genomic groups, called genomovars, to be distinguished. Members of the same genomovar have more than 70% similarity in DNA-DNA hybridizations. Members of different genomovars usually have similarity values below 50%.

### 6.2 Differentiation from other species (39)

No fluorescent pigments are produced, which differentiates *P. stutzeri* from other members of the fluorescent group of *Pseudomonas* spp. Before the use of genomic approaches to identifying bacteria became widespread, *P. stutzeri* strains were misidentified with other species. This was due to the intrinsic limitations of exclusively phenotypic identification procedures within the former genus *Pseudomonas*. *P. stutzeri* was most commonly confused with other *Pseudomonas* species (*P. mendocina*, *P. pseudoalcaligenes*, and *P. putida*); with species actually in other genera (such as *Delftia acidovorans* and *Ralstonia pickettii*); or even with the flavobacteria, *Alcaligenes* or *Achromobacter*.

Mandel proposed the species “*Pseudomonas stanieri*” for *P. stutzeri* strains with a low G+C content, around 62%; however, G+C content alone is a weak parameter for species differentiation (39).

The phylogenies of genes of the *rrn* operon, considered individually or with other housekeeping genes, demonstrate that all *P. stutzeri* strains are monophyletic. Such phylogenetic studies are currently another good tool for discriminating *P. stutzeri* from the rest of the bacterial species. *P. xanthomarina* has recently been described as a new species with only one representative strain. It is located in the same 16S rRNA phylogenetic branch as *P. stutzeri* and *P. balearica*, with sequence similarities above 98%. *P. stutzeri* can be differentiated phenotypically from both species.

### **6.3 Phenotypic characterization and identification of strain ST-201 (21, 40)**

*Pseudomonas stutzeri* strain ST-201 was a gram-negative, motile, polar monotrichous flagellated rod, strictly aerobic, non-fermentative, non-spore forming, nonfluorescent, non-pigment producing and denitrifying. The strain formed medium, smooth, opaque colonies on LB agar and colonies became dull pink upon aging. The strain grew well at 30-35°C, but not above 42°C or below 8°C (21, 40).

### **7. D-Phenylglycine aminotransferase (D-PhgAT)**

In 1997, an enzyme namely D-phenylglycine aminotransferase, D-PhgAT (EC 2.6.1.72) was isolated from a soil bacterium *Pseudomonas stutzeri* strain ST-201 and characterized (21). Subsequently, the gene encoding the enzyme, *dpgA*, was successfully cloned, sequenced, and overexpressed in *E. coli* (41). In 2003, the crystallization and preliminary X-ray crystallographic analysis of the enzyme was determined (42).

D-PhgAT, a vitamin B6-dependent enzyme, catalyzes the stereospecific amino-group transfer of D-phenylglycine to 2-oxoglutarate to yield benzoylformate and L-glutamate (Figure 14) by a reversible ping-pong kinetic mechanism (21). The enzyme requires pyridoxal-5'-phosphate (PLP) as a coenzyme and has substrate specificity for D-phenylglycine and D-4-hydroxyphenylglycine. However, neither D-

nor L-aromatic nor branch-chained amino acids can be utilized as substrates. Using the 'stereo-inverting' transamination property of D-PhgAT, the amino nitrogen can be channeled directly between D-phenylglycine and L-glutamate, a central molecule in cellular nitrogen metabolism, without the need for additional amino-acid racemases for phenylglycine or glutamate.

**Figure 14.** Stereo-inverting aminotransferase reaction catalysed by D-phenylglycine aminotransferase (D-PhgAT).

Native D-PhgAT was found as a homodimer of molecular mass 92 kDa. The enzyme was most active at alkaline pH with maximum activity at pH 9-10. The temperature for maximum activity was 35-45 °C. The apparent  $K_m$  value for D-phenylglycine and for 2-oxoglutarate at 35 °C, pH 9.5 were 1.1 and 2.4 mM, respectively. The enzyme was strongly inhibited by typical inhibitors of pyridoxal phosphate-dependent enzymes (21).

The *dpgA* gene consisted of 1,362 bps which encoded 453 amino acids of D-PhgAT. The recombinant D-PhgAT exhibited catalytic activity as expected similar to that of the native D-PhgAT including the stereo-inverting enzyme activity, the amino acid substrate specificity and kinetic properties (41).

## **CHAPTER 3**

### **MATERIALS AND METHODS**

#### **1. Bacterial strains and plasmids**

*Pseudomonas stutzeri* ST-201 was used as a wild type (wt) strain and it was available from a previous study (21). The pBluscript II SK (Stratagene) and pGEM-T Easy (Promega) were used as a cloning vector for genomic DNA restriction fragments and PCR products, respectively. The plasmids pET-17b, pET-19b and pET-24b (Novagen) were used as expression vectors of the enzyme genes. For plasmid amplification, *E. coli* JM 109 (Promega) was used as a host, whereas for gene expression, *E. coli* BL21 (DE3) and *E. coli* BL21 (DE3) pLysS (Promega) were employed.

#### **2. Chemicals and reagents**

Restriction endonuclease enzymes, DNA polymerase, DNA ligase and other molecular biology reagents were from New England Biolabs, Promega, Stratagene, Novagen or Roche Diagnostics. All other chemicals were of the highest quality commercially available from Amersham Biosciences, Sigma, Fluka, Fisher Biotech, Qiagen or other companies.

#### **3. Determining for existence of enzymes involved in mandelate and D-phenylglycine degradation in *P. stutzeri* ST-201**

To verify the existence of enzymes catabolizing substrates of interest, *P. stutzeri* ST-201 was tested for growth on minimal medium (MM) agar containing (in 1 l): 15 g agar, 3.4 g KH<sub>2</sub>PO<sub>4</sub>, 3.6 g Na<sub>2</sub>HPO<sub>4</sub>, 0.2 g MgSO<sub>4</sub>, 8 mg CaCl<sub>2</sub>, 10 mg yeast extract, 1 ml trace metals solution (43) and supplemented with an appropriate carbon source at a concentration of 10 mM: The carbon sources used were *R*-mandelate, *S*-mandelate, *D*-phenylglycine, benzoylformate and benzoate. For growth on

benzaldehyde which was immiscible with media at such concentration, a disk containing benzaldehyde (10  $\mu$ l) was placed on agar instead. With the exception of MM containing D-phenylglycine, 0.4 g NaNO<sub>3</sub> was also included as a nitrogen source. The plates were examined for evidence of growth after incubation for 48 h at 30 °C

#### **4. Study on the role of *Ps*BFDC in D-phenylglycine degradation**

To study the involvement of *Ps*BFDC in D-phenylglycine degradation, the enzyme activity of BFDC as well as D-PhgAT were monitored after the induction with different substrates. *P. stutzeri* ST-201 was grown under a shaking condition at 200 rpm in 200 ml Luria-Bertani (LB) medium at 30 °C until the culture reached an OD<sub>600</sub> of 2.8. Then, the cells were collected by centrifugation, washed with 200 ml 50 mM potassium phosphate buffer, pH 7.0 and the washed cells were added with 200 ml MM containing either glucose, D-phenylglycine or benzoylformate (10 mM). Incubation was continued under the same conditions for a further 160 min with samples being harvested every 20 min. Enzyme activity in crude cell extracts was then determined using standard assays.

#### **5. Study of wt *Ps*BFDC**

##### **5.1 Purification of wt *Ps*BFDC**

*P. stutzeri* ST-201 was grown in LB (200 ml x 16 of 500 ml flasks) at 30 °C under a shaking condition at 200 rpm until the culture reached an OD<sub>600</sub> of ~2.8. Then, the cells were collected by centrifugation, washed with 50 mM potassium phosphate buffer, pH 7.0 and the washed cells were added with 200 ml MM containing 10 mM benzoylformate. Shaking was continued at 30 °C for 9 h after which time the cells were harvested by centrifugation (Sorvall RC 5C, Dupont) and the pellet was resuspended in a 9X volume lysis buffer comprising 50 mM potassium phosphate buffer, pH 6.0, 0.1 mM ThDP and 0.1 mM phenylmethylsulphonyl fluoride (PMSF). Following ultrasonication (Vibra cell, Sonics & Materials Inc.) on ice in cycle of 20-s burst with 20-s cooling and centrifugation (10,000 g , 20 min 4 °C) the cell-free extract (CFE) was subjected to stepwise ammonium sulfate fractionation. The ammonium sulfate fraction containing BFDC was dissolved in buffer A (25 mM potassium phosphate buffer, pH 6.0, 0.1 mM ThDP, 0.1 mM MgCl<sub>2</sub>, 10 % glycerol)

and applied to a Phenyl Sepharose FF column (Amersham Biosciences) which had been connected to Biologic FPLC system (Bio-Rad) and equilibrated with buffer B (0.1 M sodium phosphate buffer, pH 6.0 and 0.1 mM ThDP) containing 1 M  $(\text{NH}_4)_2\text{SO}_4$ . The BFDC was then eluted with buffer B at a flow rate of  $2 \text{ ml min}^{-1}$ . The active fractions were pooled, concentrated and exchanged into buffer C (25 mM Tris-HCl buffer, pH 7.5, 0.1 mM ThDP) using centricon Plus-20 filtration unit cut off at 100,000 Daltons (Amicon). The concentrate was loaded onto a Q-Sepharose FF column (Amersham Biosciences) equilibrated with buffer C, and the enzyme was eluted with buffer C containing NaCl (0.75 M) at a flow rate of  $2 \text{ ml min}^{-1}$ . The purity of the active fractions was checked by SDS-PAGE using Mini-PROTEAN III system (Bio-Rad).

## 5.2 N-terminal sequencing of wt *Ps*BFDC

After the purity of the purified enzyme was confirmed, the enzyme sample was blotted onto a polyvinylidene difluoride membrane (Immobilon-P) using TransBlot SD semidry transfer cell (Bio-Rad) and subjected to N-terminal sequencing by Edman degradation at Biomolecular Research Facility (BRF), University of Newcastle, Australia.

## 6. Study of recombinant *Ps*BFDC

### 6.1 Construction of subgenomic library and cloning of *dpgB* gene

The degenerate forward primer, BFDC\_F (Table 5), was designed based on the N-terminal amino acid sequence of wt *Ps*BFDC. The reverse primer, BFDC\_R, was designed using the conserved amino acid sequences of BFDCs from *P. putida* ATCC 12633 (gi:3915757) and *P. aeruginosa* PAO1 (gi:15600094). Both primers were synthesized at Bio Basic Inc., Canada. With these primers, a 1.28-kb DNA fragment containing part of the gene encoding BFDC (*dpgB*) was amplified by polymerase chain reaction (PCR) using iNtRON's i-Taq<sup>TM</sup> DNA polymerase protocol (annealing temperature at  $55^\circ\text{C}$ ) from the genomic DNA of *P. stutzeri* ST-201. The PCR products were cloned into pGEM-T Easy (Promega), subjected to sequencing and used to generate a digoxigenin-11-dUTP (DIG-11-dUTP)-labeled *dpgB* specific

probe (Roche Diagnostics) using for southern hybridization with genomic DNA and colony hybridization with subgenomic library.

For subgenomic library construction, briefly, genomic DNA isolated from *P. stutzeri* ST-201 with the method of Sambrook et al. (44) was subjected to digestion with various restriction enzymes, followed by agarose gel electrophoresis and southern hybridization (45) using hybridization temperature at 42 °C and detection kit (Roche Diagnostics). Positive DNA fragments were eluted from 0.75% Saekem-GTG agarose gel electrophoresis by using a GFX DNA and Gel Band Purification (Amersham Biosciences) and ligated into pBluescript II SK which had been digested with the corresponding restriction enzyme(s). The ligation products were transformed into *E. coli* JM 109 by electroporation and plated on LB agar containing 50 µg ml<sup>-1</sup> ampicillin, 20 mM isopropyl-β-D-thiogalactopyranoside (IPTG) and 80 µg ml<sup>-1</sup> 5-bromo-4-chloro-3-indolyl-β-D-galactopyranoside (X-gal). White colonies containing a DNA insert were screened by colony hybridization (46) with hybridization temperature at 42 °C using Hybond-N<sup>+</sup> nylon membrane (Amersham Biosciences) and detection kit (Roche Diagnostics) to identify individual colonies carrying a plasmid containing the *dpgB* gene. The two plasmids identified in this step were designated pBCH1 and pBCH2.

## 6.2 DNA sequencing and gene analysis

The nucleotide sequences of both strands of the DNA fragment in pBCH1 and pBCH2 were determined at the BioService Unit (BSU), National Science and Technology Development Agency (NSTDA), Thailand. The open reading frames (ORFs), DNA and protein alignment were analyzed using either VectorNTI (Invitrogen) or Bioedit (<http://www.mbio.ncsu.edu/BioEdit/bioedit.html>). The nucleotide and deduced amino acid sequences were compared to the sequences in the GenBank and SwissProt databases at the National Center for Biotechnology Information (Bethesda, MD) using the BLAST network server. Both programs i.e. Pattern Recognition of SeqWeb version 2.0 of Wisconsin Package (Genetics Complete Group; GCG) and Neural Network Promoter Prediction (NNPP) were used to search for the putative promoter sequence. The GCG was also used for searching the putative ribosome binding site. The putative transcriptional terminator was determined by web-based engine at [www.bioinfo.rpi.edu/applications/mfold](http://www.bioinfo.rpi.edu/applications/mfold).

The nucleotide sequences determined in this work have been deposited under GenBank accession no EF419244.

## 6.3 Expression of *P. stutzeri* ST-201 *dpgB* gene in *E. coli* and purification of recombinant *PsBFDC*

The *dpgB* gene was PCR amplified using high fidelity *Pfu* DNA polymerase protocol (Stratagene) with annealing temperature at 55 °C and pBCH1 as the template. The forward and reverse primers, BFDC\_N and BFDC\_C (Table 5) introduced *NdeI* and *HindIII* restriction sites, respectively and were synthesized at BSU, NSTDA, Thailand. The PCR product was digested with *NdeI* and *HindIII* and ligated into pET17b. The resulting plasmid pET17b*PsBFDC* was verified for the fidelity of the amplification by sequencing at BSU, NSTDA, Thailand, and it was transformed into *E. coli* strain BL21 (DE3) (Promega).

For expression of the recombinant *PsBFDC*, the transformants were grown at 37 °C, under a shaking condition at 200 rpm, in 200 ml x 6 of 500 ml flasks of LB containing 50 µg ml<sup>-1</sup> ampicillin to an A<sub>600</sub> of 0.8 and then induced by addition of 0.4 mM IPTG. After 6 h incubation at 25 °C, the cells were harvested by centrifugation. Purification of the recombinant *PsBFDC* was accomplished using the

protocol described above for the wt *Ps*BFDC enzyme. The purified enzyme, which showed a single band on SDS-PAGE was stored at 4 °C in a storage buffer containing 50 mM sodium phosphate buffer, pH 6.0, 0.2 mM ThDP and 0.1 mM MgCl<sub>2</sub>. The protein concentration was determined by the Bradford method using bovine serum albumin as the standard (47).

## **6.4 Characterization of recombinant *Ps*BFDC**

### **6.4.1 Molecular weight determination**

Native molecular weight of the recombinant *Ps*BFDC was estimated after gel filtration chromatography with Superdex 200 HR 10/30 column (Amersham Biosciences). Purified enzyme (100 µl) was injected onto the column which was previously equilibrated with 50 mM sodium phosphate buffer, pH 7.0 containing 0.15 M NaCl at a flow rate of 0.5 ml min<sup>-1</sup>. Elution was performed with the same buffer and protein molecular weight markers including cytochrome C (12.4 kDa), carbonic anhydrase (29 kDa), albumin (66 kDa), alcohol dehydrogenase (150 kDa) and catalase (250 kDa) (Sigma) were used as the standards.

Molecular weight of the recombinant *Ps*BFDC subunits was also determined by SDS-PAGE. The enzyme was electrophoresed along with the standard markers in 4% (w/v) acrylamide for the stacking gel (pH 6.8) and 12% (w/v) acrylamide for the separating gel (pH 8.8). Protein bands were stained with Coomassie Blue.

### **6.4.2 Effect of temperature and pH on enzyme activity and stability**

The effect of temperature on the recombinant *Ps*BFDC activity was determined at temperatures ranging from 10 to 80 °C at pH 6.0. For temperature stability, the enzyme was pre-incubated between 15 and 70 °C for 20 min, after which the remaining activity was determined under the standard direct continuous assay condition described in 9.2 at 35 °C. The effect of pH on the activity was investigated using sodium citrate buffer (pH 3-6), sodium phosphate buffer (pH 6-8), Tris-HCl buffer (pH 8-9), glycine-NaOH buffer (pH 9-10) and 3-[cyclohexylamino]-1-propanesulfonic acid (CAPS) buffer (pH 10-12), each at 66 mM in the standard direct continuous assay condition at 35 °C. For pH stability, the enzyme was pre-incubated in

different buffers with varying pH at 25 °C for 20 min, after which the remaining activity was determined under the standard direct continuous assay condition at 35 °C.

### 6.4.3 Isoelectric point (pI) estimation

pI of the recombinant *Ps*BFDC was determined by isoelectric focusing (IEF) with the two-dimensional polyacrylamide gel electrophoresis from Immobiline dry strip kit (Amersham Biosciences). Briefly, the enzyme was dissolved in rehydration solution, loaded on 7-cm immobilized non-linear pH 3-10 gradient strip, rehydrated and isoelectrically focused in an automated run, IPGphor Isoelectric Focusing system. The second-dimension SDS gel was carried out in a Mini PROTEAN III cell system. Coomassie Blue staining was used to locate the protein.

### 6.4.4 Kinetic parameters study

The kinetic parameters  $K_m$  and  $k_{cat}$  were determined by assaying the enzyme activity using the standard spectrophotometric direct method at 35 °C. Benzoylformate concentrations were varied appropriately and the reactions were started by the addition of BFDC. Initial velocity data were fitted to the Michaelis-Menten equation using the Enzyme Kinetics module of SigmaPlot® (SPSS Inc.). Kinetic parameters were determined per monomer using molecular mass of 56,302 Da for *Ps*BFDC.

## 7. Study of histidine-tagged *Ps*BFDC

### 7.1 Cloning and expression of histidine-tagged *Ps*BFDC

Using pET17b*Ps*BFDC as a template, the QuikChange (Stratagene) methodology was employed to introduce an *Xho*I restriction site at the C-terminus of the *dpgB* gene. The sequence of the forward primer, BFDC\_X, is shown in Table 5. The resultant plasmid was digested with *Nde*I and *Xho*I and the 1.6 kb fragment was ligated into *Nde*I- and *Xho*I-digested pET24b, to provide a plasmid, denoted pET24b*Ps*BFDHis. Fidelity of the mutated sequence was confirmed by sequencing at the University of Michigan core facility, Life Science Institute (LSI), University of Michigan (UM), USA.

pET24b*Ps*BFDCHis was transformed into *E. coli* strain BL21(DE3)pLysS (Promega) and a single colony was used to inoculate 50 mL of LB broth containing kanamycin ( $50 \mu\text{g ml}^{-1}$ ) and chloramphenicol ( $25 \mu\text{g ml}^{-1}$ ). The culture was grown overnight at  $37^\circ\text{C}$  and used to inoculate 1 l of fresh medium. The fresh culture was grown at  $37^\circ\text{C}$  until  $\text{OD}_{600}$  reached 0.8. The culture was cooled to  $25^\circ\text{C}$ , and the protein expression was induced by the addition of 1 mM IPTG. The culture was grown for an additional 12 h at  $25^\circ\text{C}$  prior to cell harvesting by centrifugation. The pelleted cells were resuspended in buffer D (50 mM potassium phosphate buffer, pH 8.0, 500 mM NaCl, 0.1 mM ThDP) containing 10 mM imidazole and 0.1 mM PMSF, disrupted by sonication and the cell debris was removed by centrifugation. The CFE was applied to a HIS-select<sup>TM</sup> Nickel Affinity column (Sigma) previously equilibrated in buffer D. After the column was washed with buffer D containing 20 mM imidazole, the enzyme was eluted with buffer D containing 250 mM imidazole. The fractions with highest purity, as judged by SDS-PAGE, were pooled and the buffer was exchanged for storage buffer (100 mM potassium phosphate buffer, pH 6.0, 1 mM  $\text{MgSO}_4$ , 0.5 mM ThDP, 10% glycerol) using Econo-Pac 10 DG desalting columns (Bio-Rad). The protein was concentrated using Amicon Ultra centrifugal filters (Millipore) before being stored at  $-20^\circ\text{C}$ . Protein concentrations were determined by either the Bradford (47) or UV methods (48).

## 7.2 Kinetic parameters study

The kinetic parameters  $K_m$  and  $k_{cat}$  of *Ps*BFDC-his were determined by assaying the enzyme activity using the standard spectrophotometric coupled method described in 9.2 at  $30^\circ\text{C}$  and  $35^\circ\text{C}$ . Benzoylformate concentrations were varied appropriately and the reactions were started by the addition of BFDC. Initial velocity data were fitted to the Michaelis-Menten equation using the Enzyme Kinetics module of SigmaPlot<sup>®</sup> (SPSS Inc.). Kinetic parameters were determined per monomer using molecular mass of 57,367 Da for *Ps*BFDC-his.

## 8. Study of histidine-tagged benzaldehyde dehydrogenase from *P. stutzeri* ST-201 (*Ps*BADH)

### 8.1 Cloning and expression of histidine-tagged *Ps*BADH

Based on the sequence of the open reading frame in pBCH2, two primers were designed to amplify the *dpgC* gene which encoded *P. stutzeri* ST-201 benzaldehyde dehydrogenase (*PsBADH*). The forward (BADH\_F) and the reverse (BADH\_R) primers (Table 5) consisted of *NdeI* and *XhoI* sites, respectively. Amplification was achieved with *PfuUltra* DNA polymerase (Stratagene), using pBCH2 as the template. The PCR product was purified, digested and ligated into pET19b (Novagen) previously digested with *NdeI* and *XhoI*. This construction added a 10×histidine tag to the N-terminus of the enzyme and generated the expression vector, pET19b*PsBADH*-His. Fidelity of the amplification was verified by sequencing, then, the plasmid was transformed into *E. coli* strain BL21(DE3)pLysS (Promega) for expression.

Expression and preparation of a cell-free extract of his-tagged *PsBADH* were carried out similarly as described for *PsBFDC*-his. The extract was applied to HIS-Select™ Nickel Affinity column previously equilibrated in buffer E (50 mM potassium phosphate buffer, pH 8.0, 300 mM NaCl, 2 mM DTT) containing 10 mM imidazole. After washing with buffer E containing 40 mM imidazole, the enzyme was eluted in buffer E containing 250 mM imidazole. The fractions with highest purity were pooled and the buffer was exchanged for storage buffer (100 mM HEPES buffer, pH 7.5, 100 mM KCl, and 2 mM DTT) using Econo-Pac 10 DG desalting columns (Bio-Rad). The *PsBADH*-his was then concentrated using Amicon Ultra centrifugal filters (Millipore) before being stored at –20 °C.

## 8.2 Kinetic parameters study

Apparent  $K_m$  [ $K_m(\text{app})$ ] values for benzaldehyde were determined by fixing  $\text{NAD}^+$  or  $\text{NADP}^+$  at a concentration of 1 mM and varying the benzaldehyde concentrations as required. For determination of the  $K_m$  (app) values for  $\text{NAD}^+$  and  $\text{NADP}^+$ , benzaldehyde was maintained at a saturating concentration (1 mM) and the  $\text{NAD}^+$  or  $\text{NADP}^+$  concentrations varied appropriately. Kinetic data were fitted to the Michaelis-Menten equation using the Enzyme Kinetics module of SigmaPlot® (SPSS Inc.). Kinetic parameters were determined per monomer using a molecular mass of 50,278 Da for *PsBADH*-his.

## 9. Measurement of enzyme activity

### 9.1 D-PhgAT

D-PhgAT activity was determined using the spectrophotometric assay in which the rate of benzoylformate formation was measured by monitoring the increase in absorbance at 254 nm (49). The assay was carried out in a buffer (1 ml) containing Tris·HCl buffer (100 mM, pH 9.0), D-phenylglycine (1 mM),  $\alpha$ -ketoglutarate (1 mM), pyridoxal-5'-phosphate (25  $\mu$ M) and EDTA (25 mM). The assay was performed at 25 °C and the product was measured with a temperature-controlled spectrophotometer (BioSpec 1601, Shimadzu)

### 9.2 BFDC

BFDC activity was determined using a direct continuous assay based on the decrease in absorbance at 334 nm as benzoylformate was converted to benzaldehyde (4). The reaction mixture (1 ml) contained benzoylformate (8.33 mM) and ThDP (40  $\mu$ M) in sodium phosphate buffer (66 mM, pH 6.0). The assay was performed at 25 °C and the product was measured with a temperature-controlled spectrophotometer. In addition to the direct method described above a more sensitive coupled assay (9) was also used for the studies of histidine-tagged *Ps*BFDC. The assay employed decarboxylation of benzoylformate to form benzylaldehyde and followed with the use of horse liver alcohol dehydrogenase (HLADH) to convert benzylaldehyde to benzyl alcohol in the presence of NADH. The assay was performed at an appropriate temperature in 100 mM potassium phosphate buffer, pH 6.0, containing 1.0 mM MgCl<sub>2</sub>, 0.5 mM ThDP, 0.3 mM NADH and 0.25 U ml<sup>-1</sup> of HLADH. The decrease in absorbance at 340 nm was measured with a Cary 50 spectrophotometer (Varian) with a temperature-controlled cell holder.

### 9.3 BADH

Benzaldehyde dehydrogenase activity was monitored spectrophotometrically by observing the increase in A<sub>340</sub> due to the reduction of NAD<sup>+</sup> (34). Routine activity assays were carried out at 25 °C in a 1 ml reaction mixture containing 100 mM TAPS buffer, pH 8.5, 100 mM KCl, 1 mM DTT, 1 mM NAD<sup>+</sup> and 1 mM benzaldehyde. The increase in absorbance at 340 nm was measured with a Cary 50 spectrophotometer equipped with a temperature-controlled cell holder.

## CHAPTER 4

### RESULTS

#### 1. Determining for existence of enzymes involved in mandelate and D-phenylglycine degradation in *P. stutzeri* ST-201

With the exception of *R*-mandelate (10 mM) and *S*-mandelate (10 mM), *P. stutzeri* ST-201 was able to grow on MM agar containing each of the tested carbon sources; D-phenylglycine (10 mM), benzoylformate (10 mM), benzaldehyde (disk containing 10  $\mu$ L) and benzoate (10 mM).

#### 2. Study on the role of *Ps*BFDC in D-phenylglycine degradation

Neither D-PhgAT activity nor BFDC activity was observed in *P. stutzeri* ST-201 grown in MM containing 10 mM glucose (Figure 15A). However, when the culture medium was changed from LB to MM containing 10 mM D-phenylglycine, D-PhgAT activity was detected after 40 min, and was followed by BFDC activity which appeared after 100 min (Figure 15B). Conversely, in MM with 10 mM benzoylformate as the sole carbon source there was no evidence for D-PhgAT activity but BFDC activity was observed after 60 min (Figure 15C).

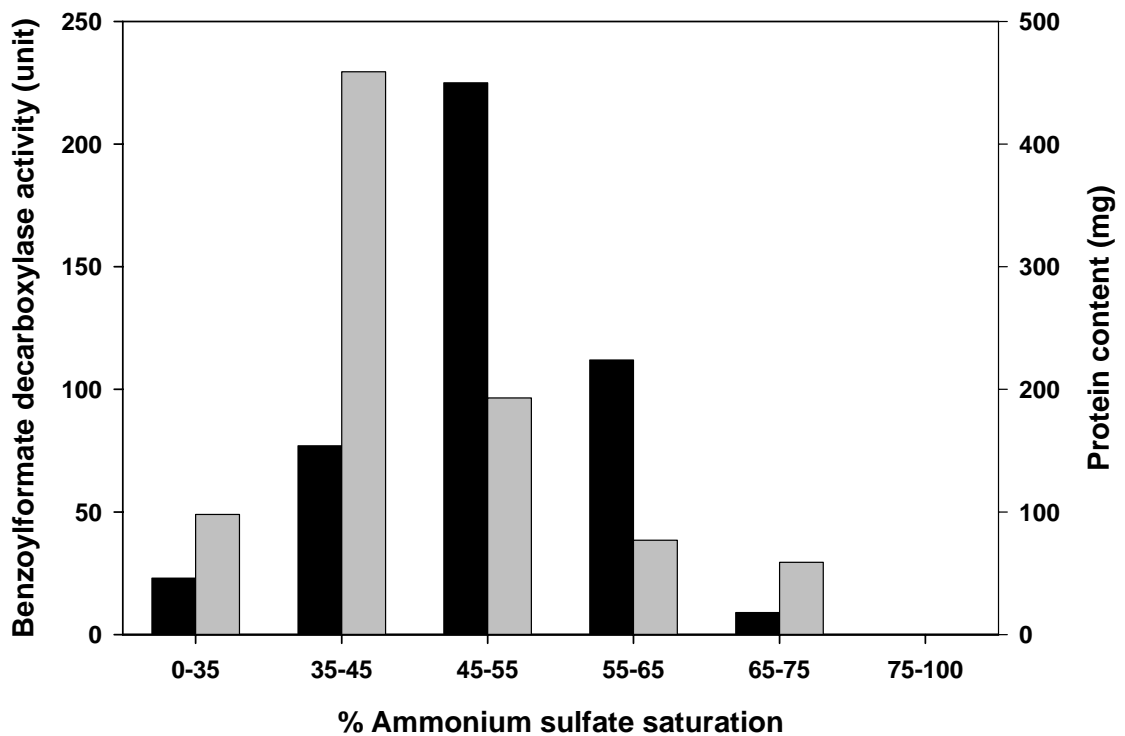

**Figure 15.** Time course for the appearance of D-phenylglycine aminotransferase (○) and benzoylformate decarboxylase (■) activity. At  $t=0$  the culture medium of *P. stutzeri* ST-201 was changed to a minimal medium containing either (A) glucose, (B) D-phenylglycine or (C) benzoylformate at the concentration of 10 mM. Enzyme activity was measured as described in Materials and Methods and expressed as relative activity to the maximum value at time = 160 min.

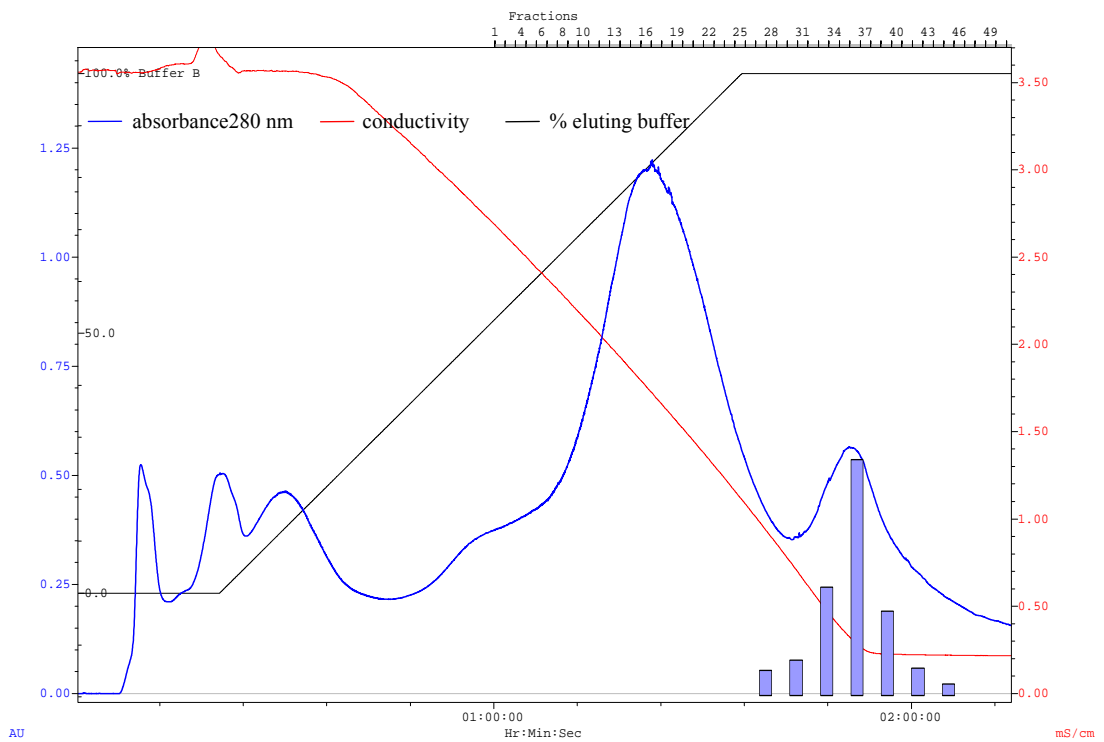

### **3. Study of wt *Ps*BFDC**

#### **3.1 Purification of wt *Ps*BFDC**

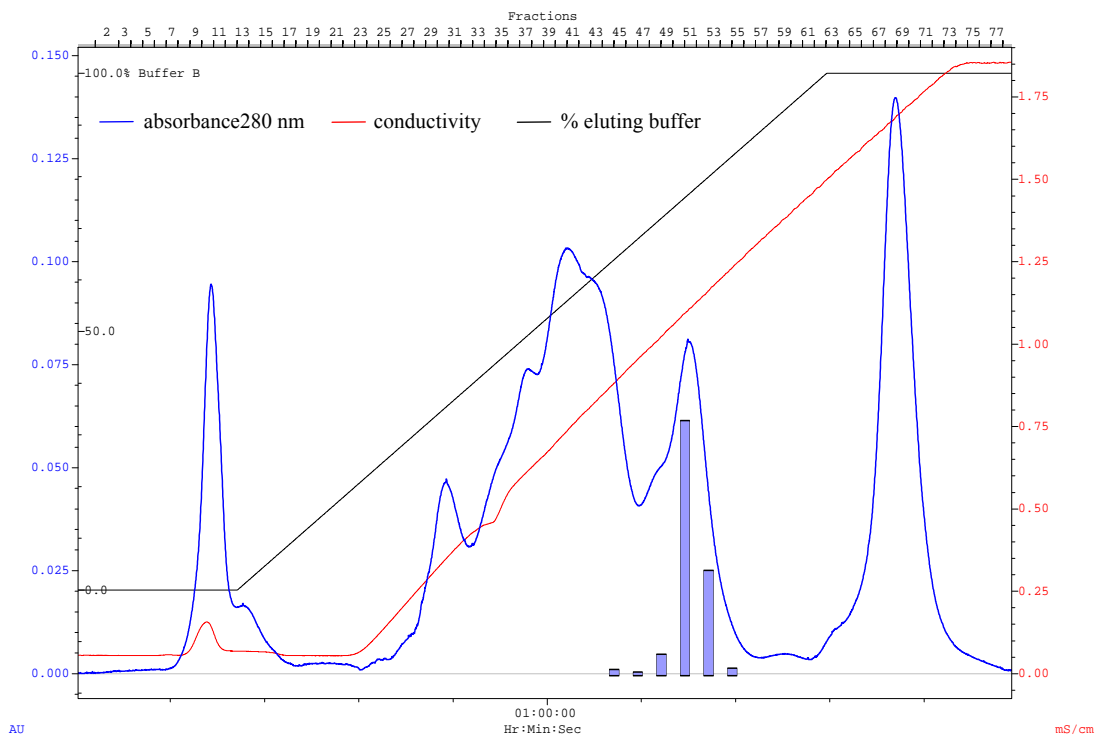

Benzoylformate decarboxylase was found in clarified cell extracts of benzoylformate-induced *P. stutzeri* ST-201 after cell disruption. By ammonium sulfate fractional precipitation, most of *Ps*BFDC precipitated at 45-65% ammonium sulfate saturation and the highest enzyme activity was observed in the fractions between 45-55% saturation (Figure 16). Subsequent hydrophobic interaction chromatography using Phenyl Sepharose FF as a chromatographic media (Figure 17) removed more than 90% of unwanted proteins. Following ultrafiltration and an anion-exchange chromatography step using a Q-Sepharose FF column (Figure 18), the active fraction gave a single band on SDS-PAGE analysis, showing a molecular weight of ~55 kDa. Results from the purification procedures are summarized in Table 6 and Figure 19.

**Figure 16.** Benzoylformate decarboxylase activity (■) and protein content (□) of ammonium sulfate precipitation fractions of clarified cell extracts. The cell extract was prepared from induced *P. stutzeri* ST-201. The enzyme activity was assayed in 66 mM sodium phosphate buffer, pH 6.0 at 25 °C.

**Figure 17.** Protein elution pattern of Phenyl Sepharose FF hydrophobic interaction chromatography. Rectangular bars represent activity of benzoylformate decarboxylase found in fractions collected by the FPLC system which were further purified in the subsequent centrifugal ultrafiltration step.

**Figure 18.** Protein elution pattern of Q-Sepharose FF anion-exchange chromatography. Rectangular bars represent activity of benzoylformate decarboxylase found in each fraction collected by the FPLC system.

**Table 6.** Summary of purification of wt BFDC from *P. stutzeri* ST-201. The culture volume of *P. stutzeri* ST-201 was 3,200 ml.

<b>Purification step</b>	<b>Total protein (mg)</b>	<b>Total activity (U)</b>	<b>Specific activity (Umg-1)</b>	<b>Purification (fold)</b>	<b>Yield (%)</b>

### **3.2 N-Terminal sequencing of wt *Ps*BFDC**

Sequencing of the purified enzyme revealed N-terminal sequence (23 amino acids) of **ASVHSITYELLRRQGIDTVFGNP** which was employed to generate degenerate primers used for hybridization experiments. The results were reliable as shown by the well identified signal peaks in HPLC chromatogram of each cycle of Edman degradation.

## **4. Construction of subgenomic library and cloning of *dpgB* gene**

### **4.1 PCR amplification of part of gene encoding *Ps*BFDC (*dpgB*)**

PCR amplification using *P. stutzeri* ST-201 chromosomal DNA template with primers BFDC\_F and BFDC\_R yielded a PCR product appeared as a single band on agarose gel (Figure 20). The size was estimated about 1,250-1,280 base pairs, which was as expected when compared to that of the deposited BFDC gene (*mdlC*) of *P. putida* ATCC 12633.

**Figure 20.** Agarose gel electrophoresis of PCR product for probe preparation.

Lane 2: PCR product amplified from *P. stutzeri* ST-201 genomic DNA with primers BFDC\_F and BFDC\_R

#### 4.2 DNA sequence of the PCR product

The PCR product was cloned to pGEM-T Easy and submitted for DNA sequence determination at the BSU, NSTDA, Thailand. The result of nucleotide sequencing was shown as a 1,253 base pairs in which the two primers were identified at both ends in Figure 21.

**Figure 21.** Nucleotide sequence of the 1,253-bp PCR product derived from primers BFDC\_F and BFDC\_R in amplifying genomic DNA from *P. stutzeri* ST-201. The bold letters are primers in both ends.

#### 4.3 Identity of 1,253-bp PCR product

Using the primer sequence as a reference of reading frame, deduced amino acid sequence of 1,253-bp PCR product showed perfect matching with that of the remaining amino acid as shown in Figure 22. The evidence strongly confirmed that correct priming by both N-terminal degenerate primers and internal primers occurred. Thus, the PCR product could then be used as a *Ps*BFDC gene (*dpdB*)-specific probe.

**Figure 22.** Deduced amino acid sequence translated from the 1,253-bp PCR product. Bold letters show the amino acid sequences that are in agreement with the known amino acid sequence determined by protein sequencing of the N-terminal peptide. Underlined letters are amino acid sequences encoded by primer sequences.

#### 4.4 Similarity search of 1,253-bp PCR product

The deduced amino acid sequence of the 1,253-bp PCR product was analyzed for sequence similarity to the existing protein sequences available in the database at GenBank and SwissProt at the National Center for Biotechnology Information (Bethesda, MD) using the BLAST network server. By performing BLASTp search against non-redundant protein sequences, the results revealed that the score and E-value showed significant similarity to known BFDC from *P. putida* ATCC 12633 (*Pp*BFDC). This information suggested that the 1,253-bp PCR product was potentially a part of the gene encoding for BFDC enzyme. Result of BLASTp search on the database using the translated amino acid sequence of the 1,253-bp PCR product is shown in Figure 23.

## 4.5 Subgenomic DNA library construction and isolation of positive clone

### 4.5.1 Southern hybridization of complete digestion of genomic DNA

Southern hybridization analysis of DNA fragments generated from complete digestion of genomic DNA and detecting with the digoxigenin-labeled 1,253-bp *dpgB*-specific probe showed that *EcoRI* combined with *HindIII* or *SalI* gave positive bands of about 5-7 kb as shown in Figure 24 and *EcoRV* or *PstI* alone gave positive bands of 4 kb as shown in Figure 25.

**Figure 24.** (A) Agarose gel electrophoresis of complete double digestion of *P. stutzeri* ST-201 genomic DNA by two restriction enzymes. (B) Southern hybridization of the corresponding gel with the digoxigenin-labeled 1,253-bp PCR product (*dpgB* gene-specific probe).

Lane 1:  $\lambda$  DNA/*Hind* III markers and M 13 100 bp + 1.5 Kb DNA Ladder

Lane 2: complete digestion of genomic DNA by *Eco*RI

Lane 3: complete digestion of genomic DNA by *Eco*RV

Lane 4: complete digestion of genomic DNA by *Hind*III

Lane 5: complete digestion of genomic DNA by *Pst*I

Lane 6: complete digestion of genomic DNA by *Pvu*II

Lane 7: complete digestion of genomic DNA by *Xho*I

Lane 8: 1,253-bp PCR product

Among the enzymes used, *Eco*RI combined with *Hind*III and *Pst*I alone were selected to generate a DNA pool for construction of enriched subgenomic DNA library. This was based on the assumption that the whole *dpgB* gene which encoded for the 55 kDa *Ps*BFDC should be about 1.6 Kb in size and should reside in restriction fragments of 5-7 kb or 4 kb.

#### 4.5.2 Colony hybridization of the subgenomic library

The first subgenomic DNA library was constructed by transforming ligated products of the 5-7 Kb *EcoRI-HindIII* fragments with *EcoRI-HindIII*-digested pBluescript II SK into *E. coli* JM 109. The second subgenomic DNA library was constructed by transforming ligated products of the 4 Kb *PstI* fragments with *PstI*-digested pBluescript II SK into *E. coli* JM 109. The two libraries were screened by colony hybridization with the digoxigenin-labeled 1,253-bp *dpgB* probe. Of about four hundred colonies screened in each library, one positive colony with strong hybridization signal were found as shown in Figure 26 and 27 which designated as pBCH1 and pBCH2, respectively.

**Figure 26.** Colony hybridization of the enriched subgenomic DNA library of 5-7 kb *EcoRI-HindIII* restriction fragments with the digoxigenin-labeled 1,253-bp *dpgB* probe. Result showed one positive colony with a distinctive color as compared to the background. *E. coli* JM 109 harboring pBluescript II SK was used as the negative control (-). *E. coli* JM 109 with pGEM-T Easy containing 1,253-bp PCR product was used as the positive control (+).

**Figure 27.** Colony hybridization of the enriched DNA library of 4 kb *Pst*I restriction fragments with the digoxigenin-labeled 1,253-bp *dpgB* probe. Result showed one positive colony with a distinctive color as compared to background. *E. coli* JM 109 harboring pBluescript II SK was used as the negative control (-). *E. coli* JM 109 with pGEM-T Easy containing 1,253-bp PCR product was used as the positive control (+).

## 4.6 Nucleotide sequence of positive DNA restriction fragment from library screening

### 4.6.1 Nucleotide sequence of 6.3 kb *EcoRI*-*HindIII* insert of pBCH1

The nucleotide sequencing of 6.3 kb *EcoRI*-*HindIII* insert DNA in pBCH1 revealed that the insert was 6,273 base pairs long (Figure 28) with an open reading frame (ORF) of 1,581 base pairs which was denoted *dpgB* (Figure 29) and encoded a protein of 526 amino acids with a deduced molecular mass of 56 kDa.

**Figure 29.** *Ps*BFDC ORF of 1,581 bp which was denoted as *dpgB* (A) and its deduced amino acids of 526 residues (B) are located in the the 6.3 kb *EcoRI-HindIII* insert DNA in pBCH1. The start codon ATG and stop codon TGA of *dpgB* are in bold letters and highlighted. The putative promoter sequences (-35 and -10), +1 start site, putative ribosome binding site (RBS) and putative ρ-independent transcriptional terminator are in bold letters and underlined.

#### 4.6.2 Nucleotide sequence of 4 kb-*Pst*I insert of pBCH2

The 4 kb *Pst*I insert DNA in pBCH2 was subjected to DNA sequence determination at the BSU, NSTDA, Thailand. The result of nucleotide sequencing was shown as a 4,041 bps long in Figure 30. Sequencing of pBCH2 identified a region which corresponded to part of the *dpgB* gene. However, this insert also carried the full length ORF of 1,311 bp downstream of *dpgB*. The ORF, denoted *dpgC* which was later identified as a gene encoding for benzaldehyde dehydrogenase (*Ps*BADH) as shown in Figure 31, transcribed in the same direction as *dpgB* and encoded a protein of 436 amino acids with a deduced molecular mass of 47.7 kDa.

#### 4.6.3 Nucleotide sequence of 7.65 kb - overlapped fragment of 6.3 kb *EcoRI*- *HindIII* insert and 4 kb *PstI* insert

The 6.3 kb (6,273 base pairs) *EcoRI*- *HindIII* insert DNA in pBCH1 and the 4 kb (4,041 base pairs) *PstI* insert DNA in pBCH2 were overlapped and combined to be 7.65 kb (7,653 base pairs) genomic DNA fragment which was shown in Figure 32. Consequently, the 7.65 Kb fragment contained both *dpgB* gene and *dpgC* gene. The sequence of the combined fragment has been deposited under GenBank accession no. EF419244.

**Figure 32.** Nucleotide sequence of the 7.65 kb combined fragment. The *Hind*III and *Pst*I sites are underlined at 5' and 3' end of the fragment, respectively. This fragment contains the whole *dpgB* gene encoding for *Ps*BFDC in bold letters and the whole *dpgC* gene encoding for *Ps*BADH in bold and italic letters (continued).

#### **4.7 Sequence homology between BFDC from *P. stutzeri* ST-201 (*Ps*BFDC) and BFDC from other *Pseudomonas* species**

Multiple sequence alignment of BFDC from *P. stutzeri* ST-201 (*Ps*BFDC) to that of BFDC from other *Pseudomonas* species using the Clustal W algorithm of multiple alignments is shown in Figure 33. The results show the identity between *Ps*BFDC and BFDC from *P. putida* ATCC 12633 (*Pp*BFDC) is 91%, and the identity between *Ps*BFDC compared with BFDC from *P. aeruginosa* PAO1 (*Pa*BFDC) is 63%.

**Figure 33.** Multiple amino acid sequence alignment of BFDC from *P. stutzeri* ST-201 (*PsBFDC*) with BFDC from *P. putida* ATCC 12633 (*PpBFDC*) and BFDC from *P. aeruginosa* PAO1 (*PaBFDC*). Dark and light shadings show identical and similar residues among sequences. Amino acids tagged with a dot are residues implicated in the catalytic mechanism of BFDC.

### 4.8 Homology between BADH from *P. stutzeri* ST-201(*PsBADH*) and BADH from *P. putida* ATCC 12633 (*PpBADH*)

Multiple sequence alignment of BADH from *P. stutzeri* ST-201 (*PsBADH*) to that of BADH from *P. putida* ATCC 12633 (*PpBADH*) using the Clustal W algorithm of multiple alignment is shown in Figure 34. The results show identity between *PsBADH* and *PpBADH* is 86%.

**Figure 34.** Multiple amino acid sequence alignment of BADH from *P. stutzeri* ST-201 (*PsBADH*) to that of BADH from *P. putida* ATCC 12633 (*PpBADH*). Dark and light shadings show identical and similar residues among sequences. Amino acids involved in catalytic mechanism are indicated by dot. A residue tagged with an asterisk is involved in linking conserved domains in class 3 aldehyde dehydrogenase.

## 5. Expression of *P. stutzeri* ST-201 *dpgB* gene in *E.coli* and purification of recombinant *Ps*BFDC

BFDC activity was found in the CFE from IPTG-induced *E. coli* BL21 (DE3) harboring the plasmid pET17b*Ps*BFDC. The majority of the BFDC activity precipitated at 45–65% ammonium sulfate saturation (Figure 35). Following hydrophobic interaction chromatography using Phenyl Sepharose FF as a chromatographic media (Figure 36), centrifugal ultrafiltration and ion-exchange chromatography using a Q-Sepharose FF column (Figure 37), the enzyme ran as a single band by SDS-PAGE analysis. The purified enzyme, which showed a single band on SDS-PAGE was stored at 4 °C in a storage buffer containing 50 mM sodium phosphate buffer, pH 6.0, 0.2 mM ThDP and 0.1 mM MgCl<sub>2</sub> and used for further characterization. Results from the purification procedure are summarized in Table 7 and Figure 38.

**Figure 35.** Benzoylformate decarboxylase (BFDC) activity (■) and protein content (□) ammonium sulphate precipitation fractions of cell-free extracts. The cell extracts were prepared from IPTG-induced *E. coli* BL21 (DE3) harboring the plasmid pET17b*Ps*BFDC. The enzyme activity was assayed in 66 mM sodium phosphate buffer, pH 6.0 at 25 °C.

**Figure 36.** Protein elution pattern of Phenyl Sepharose FF hydrophobic interaction chromatography. Rectangular bars represent activity of benzoylformate decarboxylase found in each fraction collected by the FPLC system for concentration and purification by using centrifugal ultrafiltration.

**Figure 37.** Protein elution pattern of Q-Sepharose FF anion-exchange chromatography. Rectangular bars represent activity of benzoylformate decarboxylase found in each fraction collected by the FPLC system.

**Table 7.** Summary of purification of recombinant BFDC from *P. stutzeri* ST-201. The culture volume of *E.coli* strain BL21 (DE3) was 1,200 ml.

<b>Purification step</b>	<b>Total protein (mg)</b>	<b>Total activity (U)</b>	<b>Specific activity (Umg-1)</b>	<b>Purification (fold)</b>	<b>Yield (%)</b>
1. Clarified cell homogenate	260	24180	93	1.0	100

## 6. Characteristics of recombinant *Ps*BFDC

### 6.1 Molecular weight

#### 6.1.1 Native molecular weight

The molecular weight of native recombinant *Ps*BFDC was estimated after gel filtration chromatography with the Superdex 200 HR 10/30 column running with the FPLC system as shown in Figure 39. A standard calibration curve between log molecular weights of protein markers and the partition coefficient values,  $K_{av}$  was constructed. The results are shown in Figure 40 and that the molecular weight of the native recombinant *Ps*BFDC was estimated to be 224 kDa.

**Figure 39.** Protein elution pattern of Superdex 200 HR 10/30 gel filtration chromatography. Rectangular bars represent activity of benzoylformate decarboxylase found in each fraction collected by the FPLC system.

**Figure 40.** A standard calibration curve for native molecular weight determination of recombinant *PsBFDC* by a Superdex 200 HR 10/30 column. The protein molecular weight markers were: cytochrome C (12.4 kDa), carbonic anhydrase (29 kDa), albumin (66 kDa), alcohol dehydrogenase (150 kDa) and catalase (250 kDa). The partition coefficient values,  $K_{av}$  as plotted against log molecular weights of each protein. The molecular weight of native recombinant *PsBFDC* was estimated to be 224,000 Da.

### 6.1.2 Molecular weight of enzyme subunit

The molecular weight of recombinant *Ps*BFDC subunit was estimated after SDS-PAGE analysis. The enzyme was electrophoresed along with the standard. A standard calibration curve between log molecular weights of protein markers and the relative mobility,  $R_f$  was constructed. The results are shown in Figure 41 and that the molecular weight of native recombinant *Ps*BFDC was estimated to be 56 kDa.

**Figure 41.** A standard calibration curve for determining molecular weight of enzyme subunit of recombinant *Ps*BFDC by SDS-PAGE analysis. The protein molecular weight markers were:  $\beta$ -lactoglobulin (18.4 kDa) RE Bsp981 (25.0 kDa), lactate dehydrogenase (35.0 kDa), ovalbumin (45.0 kDa), bovine serum albumin (66.2 kDa) and  $\beta$ -galactosidase (116 kDa). The relative mobility,  $R_f$  was plotted against log molecular weight of each protein. The molecular weight of recombinant *Ps*BFDC subunit was estimated to be 56,000 Da.

## 6.2 Effect of temperature and pH

### 6.2.1 Effect of temperature on enzyme activity

Effect of temperature on the recombinant *PsBFDC* activity was determined under the standard direct continuous assay condition at temperatures ranging from 10 to 80 °C. The temperature-activity profile of *PsBFDC* is shown in Figure 42. *PsBFDC* activity increased with increasing temperature up to 45 °C. It then sharply declined when the temperature was above 55 °C and the enzyme was inactivated at 70 °C. In the temperature range of 35-50 °C, the enzyme was found to be most active.

**Figure 42.** Effect of temperature on the recombinant *PsBFDC* activity. *PsBFDC* activity was determined under the standard direct continuous assay condition at temperatures ranging from 10 to 80 °C. *PsBFDC* activity values were expressed as relative activity to the maximum value. Data plotted were averages of triplicate experiments.

### 6.2.2 Effect of temperature on enzyme stability

Effect of temperature on the recombinant *Ps*BFDC stability was studied by pre-incubating the enzyme at various temperatures from 15 to 80 °C for 20 min, after which the remaining activity was determined under the standard direct continuous assay condition at 35 °C. The thermal stability profile of *Ps*BFDC is shown in Figure 43. *Ps*BFDC was found to be stable up to 50 °C. It was, then, deteriorated when the temperature was higher and the enzyme was completely inactivated at 70 °C

**Figure 43.** Effect of temperature on the recombinant *Ps*BFDC stability. In this experiment, the enzyme was pre-incubated at the temperatures between 15 and 80 °C for 20 min, after which the remaining activity was determined under the standard direct continuous assay condition at 35 °C. *Ps*BFDC activity values were expressed as relative activity to the maximum value. Data plotted were averages of triplicate experiments.

### 6.2.3 Effect of pH on enzyme activity

Effect of pH on the recombinant *Ps*BFDC activity was investigated in sodium citrate buffer (pH 3-6), sodium phosphate buffer (pH 6-8), Tris-HCl buffer (pH 8-9), glycine-NaOH buffer (pH 9-10) and 3-[cyclohexylamino]-1-propanesulfonic acid (CAPS) buffer (pH 10-12), each at 66 mM in standard direct continuous assay condition at 35 °C . The relationship between pH and *Ps*BFDC activity is shown in Figure 44. The optimal pH of *Ps*BFDC was found to be at 6.0 and reduction in activity was found at pH values below pH 5.5 and over 7.5.

**Figure 44.** Effect of pH on the activity of recombinant *Ps*BFDC. Different buffers were used in the study; sodium citrate buffer (●), sodium phosphate buffer (▲), Tris-HCl buffer (▼), Glycine-NaOH buffer (■) and CAPS buffer (◆). Relative activities were expressed in the study. Data plotted were averages of triplicate experiments.

#### 6.2.4 Effect of pH on enzyme stability

Effect of pH on the recombinant *Ps*BFDC stability was studied by pre-incubating the enzyme in different buffers with different pH from 3 to 12 for 20 min, after which the remaining activity was determined under the standard direct continuous assay condition at 35 °C. The pH stability profile of *Ps*BFDC is shown in Figure 45. *Ps*BFDC was found to be most stable at pH 6.0 in sodium phosphate buffer. The enzyme stability declined when pH was lower 5.0 and higher than 7.0.

**Figure 45.** Effect of pH on stability of recombinant *Ps*BFDC. Different buffers were used in the study; sodium citrate buffer (●), sodium phosphate buffer (▲), Tris-HCl buffer (▼), Glycine-NaOH buffer (■) and CAPS buffer (◆). Relative activities were expressed in the study. Data plotted were averages of triplicate experiments.

### 6.3 Isoelectric point (pI) estimation

pI of the recombinant *PsBFDC* was determined by isoelectric focusing in an automated run, IPGphor Isoelectric Focusing system of the two-dimensional polyacrylamide gel electrophoresis from Immobiline Dry strip kit. By using a highly guaranteed reproducible standard calibration curve between pH versus % gel length provided by the kit's supplier (Amersham Biosciences), pI of the native recombinant *PsBFDC* was estimated to be 5.2.

**Figure 46.** A standard calibration curve for pI estimation and a plot representing the pI of native recombinant *PsBFDC* (pI = 5.2).

#### 6.4 Kinetic parameters

Table 8 shows Michaelis-Menten parameters of *Ps*BFDC as well as *Ps*BFDC-his and *Pp*BFDC-his. The experiments were performed at the temperature 30 or 35 °C and at pH 6.0. The data are the averages of at least 3 separate experiments and are reported as  $\pm$  SD.

**Table 8.** Kinetic parameters for *Ps*BFDC.

Enzyme	Temperature (°C)	$K_m$ (mM)	$k_{cat}$ ( $s^{-1}$ )	$k_{cat} / K_m$ ( $s^{-1} M^{-1}$ )
wt <i>Ps</i> BFDC	35	$0.69 \pm 0.10$	$222 \pm 3$	$3.2 \times 10^5$
<i>Ps</i> BFDC-his	35	$0.44 \pm 0.07$	$284 \pm 12$	$6.4 \times 10^5$
<i>Ps</i> BFDC-his	30	$0.43 \pm 0.05$	$213 \pm 7$	$5.0 \times 10^5$
<i>Pp</i> BFDC-his <sup>a</sup>	30	$0.54 \pm 0.05$	$342 \pm 13$	$6.3 \times 10^5$

<sup>a</sup> Data from Lingen et al. (17)

#### 7. Expression and purification of histidine-tagged *Ps*BFDC

ThDP-dependent enzymes are often purified as his<sub>6</sub>-tagged variants to avoid loss of activity during multi-step purifications (14, 50). So, to facilitate a more rapid purification, *Ps*BFDC in this study was also prepared and expressed with a C-terminal histidine tag, and a homogenous preparation was obtained in a single step purification as shown by SDS-PAGE (Figure 47).

**Figure 47.** The purity of *PsBFDC-his* obtained from single step purification after His-Select nickel affinity chromatography.

Lane 3: After His-Select nickel affinity chromatography

## 8. Study on benzaldehyde dehydrogenase from *P. stutzeri* ST-201 (*PsBADH*)

### 8.1 Preparation and purification of histidine-tagged *PsBADH*

The *dpgC* gene which encoded *PsBADH* was amplified from pBCH2 and placed in the expression vector pET19b which adds an N-terminal His<sub>10</sub>-tag. The enzyme was purified in a single step using a nickel affinity column. The purified protein showed a single band on SDS-PAGE with an estimated molecular mass consistent with that calculated from the gene sequence (Figure 48).

**Figure 48.** The purity of *PsBADH*-his obtained from single step purification after His-Select nickel affinity chromatography.

Lane 1: Molecular mass standards (kDa)

Lane 2: Crude cell lysate

Lane 3: After His-Select nickel affinity chromatography

### 8.2 Kinetic parameters

Table 9 shows Michaelis-Menten parameters of *PsBADH* studied at 25 °C and pH 8.5. The data are the means of at least 3 separate experiments and are reported as  $\pm$  SD. Concentration of the fixed substrate was maintained at 1 mM.

**Table 9.** Kinetic parameters for *PsBADH*.

Variable substrate	Fixed substrate	$K_m(\text{app})$ ( $\mu\text{M}$ )	$k_{\text{cat}}$ ( $\text{s}^{-1}$ )	$k_{\text{cat}} / K_m$ ( $\text{s}^{-1} \text{M}^{-1}$ )
Benzaldehyde	$\text{NAD}^+$	$7.1 \pm 0.6$	$57 \pm 8$	$8.0 \times 10^6$
Benzaldehyde	$\text{NADP}^+$	$6.9 \pm 0.4$	$6.4 \pm 0.4$	$9.3 \times 10^5$
$\text{NAD}^+$	Benzaldehyde	$997 \pm 111$	$176 \pm 9$	$1.8 \times 10^5$
$\text{NADP}^+$	Benzaldehyde	$6140 \pm 375$	$40 \pm 3$	$6.5 \times 10^3$

## CHAPTER 5

### DISCUSSION

#### 1. Enzymes involved in mandelate and D-phenylglycine degradation in *P. stutzeri* ST-201

With the exception of *R*- and *S*-mandelate, *P. stutzeri* ST-201 was able to grow on MM agar containing each of the tested carbon sources. The results demonstrated that the organism could produce enzymes capable of catabolizing D-phenylglycine, benzoylformate, benzaldehyde and benzoate but not *R*- and *S*-mandelate. Therefore, the results suggested that *P. stutzeri* ST-201 lacked *S*-mandelate dehydrogenase and/or mandelate racemase which both were found in the mandelate pathway of *P. putida* ATCC 12633 (Figure 2) (3).

#### 2. Induction of *Ps*BFDC in D-phenylglycine degradation pathway

As previously reported, benzoylformate was found in cultures of *P. stutzeri* ST-201 grown on D-phenylglycine (21). Therefore, the most likely reaction involved was the transamination of D-phenylglycine in the initial step of D-phenylglycine degradation as proposed in Figure 2. Furthermore, *P. stutzeri* ST-201 could grow on the substrates shown as intermediates in the proposed pathway suggesting that the catabolizing enzymes including benzoylformate decarboxylase and benzaldehyde dehydrogenase might exist. Whether or not these enzymes including D-PhgAT are coordinately regulated need to be proven. In *P. putida* ATCC 12633 some of the enzymes of the mandelate pathway are coordinately regulated. BFDC activity, for example, can be induced by the addition of either *R*- or *S*-mandelate or benzoylformate (but not benzoate) to the culture medium (3). In *P. stutzeri* ST-201 neither D-PhgAT activity nor BFDC activity was observed in MM containing glucose (Figure 15A). However, when the culture medium was changed from LB to MM containing D-phenylglycine, D-PhgAT activity was detected after 40 minutes, and was

followed by BFDC activity which appeared after 100 min (Figure 15B). Conversely, in MM with benzoylformate as the sole carbon source there was no D-PhgAT activity detected but BFDC activity was observed after 60 min (Figure 15C). Evidently, benzoylformate induces only the expression of the BFDC whereas D-phenylglycine brings about an increase in the levels of both enzymes. What is not clear is whether this is because D-phenylglycine actually induces the genes for both enzymes or whether the gene for D-PhgAT is induced and the benzoylformate subsequently produced induces the BFDC gene. Based on the times at which the two enzyme activities are observed the latter is the most likely explanation. Regardless, the sequential expression of the enzymes substantiates the involvement of BFDC in the pathway in a step following D-phenylglycine degradation.

### 3. Purification of wt *Ps*BFDC

When cell-free extract from the benzoylformate-induced *P. stutzeri* ST-201 culture was assayed for BFDC activity, there was a decrease with time in the absorbance of benzoylformate due to substrate depletion, as well as the occurrence of the characteristic odor of benzaldehyde product. These results also imply that *P. stutzeri* ST-201 probably produced BFDC. Nevertheless, the presence of a *Ps*BFDC could only be confirmed by purification of the enzyme to homogeneity. This was achieved in a series of four steps including ammonium sulfate fractionation, followed by hydrophobic interaction chromatography, centrifugal ultrafiltration and ion-exchange chromatography. At the end of these steps, the SDS-PAGE analysis showed a single protein band with a molecular weight of ~55 kDa.

In ammonium sulfate precipitation step, most of the enzyme was precipitated at 45-65% saturation which indicated that enzyme is rather hydrophobic in nature. Hydrophobic interaction chromatography was chosen as the next purification step because the proteins were in a high salt medium, so no desalting step was required prior to column loading. In the following step, the enzyme was purified and concentrated in one step by ultrafiltration in which molecules smaller than 100 kDa were removed. Finally, Q-Sepharose FF ion-exchange chromatography effectively purified the enzyme to yield *Ps*BFDC with 492 fold purification and with 23% yield. The purified wt *Ps*BFDC had a specific activity of 177 U mg<sup>-1</sup>. In the previous report

by Hegeman working with *P. putida*, specific activity of the purified wt *Pp*BFDC was 193 U mg<sup>-1</sup> (4).

#### 4. N-terminal amino acid sequence of wt *Ps*BFDC

Sequencing of the purified enzyme informed an N-terminal sequence of ASVHSITYELLRRQGIDTVFGNP, which was useful for two purposes. First, it was compared with the amino acid sequences deposited in available databases. The BlastP search with 23 amino acids sequence from 55 kDa wt *Ps*BFDC protein indicated a 91% identity with N-terminal amino acids sequence lacking methionine of *Pp*BFDC. Therefore, 55 kDa wt *Ps*BFDC protein was likely confirmed to be ThDP-dependent BFDC. The other purpose was to use this sequence for the design of degenerate primer employed in the gene cloning.

#### 5. Physical structure, orientation and classification of *dpgB* gene and its product

Two clones containing *dpgB* gene designated as pBCH1 and pBCH2 were obtained after detecting with the *dpgB* gene-specific probe (1,253-bp). The probe was constructed by PCR labeling with forward degenerate primer from N-terminal amino acids sequence of wt *Ps*BFDC and reverse primer from consensus cofactor-binding region of orthologous genes of *Pp*BFDC and *Pa*BFDC. The probe was used in southern hybridization as well as colony hybridization with subgenomic DNA libraries.

Sequencing of pBCH1 revealed an open reading frame (ORF) of 1,581 base pairs denoted *dpgB*. It encoded a protein of 526 amino acids with a deduced molecular mass of 56 kDa. This was in good agreement with the size observed on SDS-PAGE (55 kDa) for the BFDC purified from induced *P. stutzeri* ST-201 cells. In addition, the deduced amino acid sequence of the N-terminal 23 amino acids of *dpgB* was identical to that of the native *Ps*BFDC lacking the N-terminal methionine.

BLASTp analysis of the deduced amino acid sequence of *dpgB* revealed significant homology to other bacterial benzoylformate decarboxylases, with the highest sequence identity being 91% to *Pp*BFDC (gi:3915757) and 63% to *Pa*BFDC (gi:15600094) (Figure 33). Those residues implicated in the catalytic mechanism of *Pp*BFDC, including Ser26, Glu47, His70 and His281 (11), all were also conserved in

*Ps*BFDC. Analysis of the DNA sequence upstream of *dpgB* gene identified a putative ribosome binding site and -10 and -35 putative promoter regions. No ORF was identified in the 300 bp sequence upstream from *dpgB* while downstream of the *dpgB* ORF a putative  $\rho$ -independent transcriptional terminator with  $\Delta G = -9.7 \text{ kcal mol}^{-1}$  was identified. In addition a partial ORF of *dpgC* was found about 250 bp downstream of *dpgB* (Figure 49A). Overall these results suggested that *dpgB* was transcribed monocistronically, unlike the gene encoding *Pp*BFDC which was arranged and transcribed in the *mdlCBA* operon (Figure 49B) (8).

**Figure 49.** (A) Restriction fragment of the genomic DNA from *P. stutzeri* ST-201 carrying the genes for benzoylformate decarboxylase (*dpgB*) and benzaldehyde dehydrogenase (*dpgC*). The fragment (7.65 kb) shown is the combination of two overlapping genomic DNA fragments contained in pBCH1 and pBCH2. The arrows show the position and orientation of the genes, and relevant restriction sites are indicated. The sequence of the combined fragment has been deposited under GenBank accession no. EF419244. (B) Organization of the mandelate pathway genes based on GenBank accession no. AY143338. Benzoylformate decarboxylase (*mdlC*), *S*-mandelate dehydrogenase (*mdlB*) and mandelate racemase (*mdlA*) make up the *mdlCBA* operon while benzaldehyde dehydrogenase (*mdlD*) is transcribed independently.

The evidence for BFDC activity coupled with the observations that *P. stutzeri* ST-201 was able to grow on benzaldehyde and that benzoate could be found in the culture medium, suggested the likely presence of a BADH. Consequently, it was not surprising when a BLAST search of the full length amino acid sequence indicated that the *dpgC* gene product was likely to be an aldehyde dehydrogenase, probably of the class 3 type. Dehydrogenases of this class are characterized by the ability to utilize both  $\text{NAD}^+$  and  $\text{NADP}^+$  (51). The *dpgC* gene sequence was 86% identical to that of the BADH from *P. putida* ATCC 12633 *PpBADH* (34) (Figure 34). The catalytic residues, including the catalytic thiol (Cys249) and the general base (Glu337) were conserved as was the aspartic acid residue (Asp253) that links conserved domains in class 3 aldehyde dehydrogenases (52). *PsBADH* also shared 30-40% sequence identity with other aldehyde dehydrogenases from pseudomonads, including the *p*-hydroxy-benzaldehyde dehydrogenase from *P. putida* NCIMB 9866 (53). However, although they are closely related phylogenetically, the other pseudomonad aldehyde dehydrogenases are not class 3 enzymes (51).

## **6. Expression of *P. stutzeri* ST-201 *dpgB* gene in *E. coli* and characterization of recombinant *PsBFDC***

Pure recombinant *PsBFDC* was successfully achieved using the same protocol as that with wt *PsBFDC*, i.e., using a series of four steps including ammonium sulfate fractionation, followed by hydrophobic interaction chromatography, centrifugal ultrafiltration and ion-exchange chromatography. The enzyme was finally purified 2.6 fold with 13% yield. The purified recombinant *PsBFDC* had a specific activity of  $243 \text{ U mg}^{-1}$ .

The subunit molecular mass of the recombinant enzyme by SDS-PAGE, ~56 kDa, was in good agreement with the molecular mass calculated from the *dpgB* gene sequence, 56 kDa. Superdex 200 HR 10/30, gel-filtration experiments provided a native molecular mass of ~224 kDa. This indicated that BFDC from *P. stutzeri* ST-201 associates as a homotetramer, a characteristic common in bacterial BFDCs (5, 13). Crystal structure of *PpBFDC* has demonstrated that the active tetramer are assembled by binding the cofactors ThDP,  $\text{Mg}^{2+}$  and  $\text{Ca}^{2+}$  (13), whereas monomers and dimers of indolepyruvate decarboxylase are inactive (54).

The enzyme was active over a broad range of temperature with maximum activity at 35-50 °C which was similar to that of the BFDC from *Neurospora crassa* (40 °C) (7). The effect of temperature on enzyme stability showed that the enzyme was stable up to 50 °C. Higher temperature gradually inactivated the enzyme and complete inactivation was registered after heating at 70 °C.

The enzyme showed optimal pH at 6.0 which was similar to that of the BFDC from *P. putida* (pH 6.2) (4) and reduced activity was observed at pH values over 7.5 and below pH 5.5. Loss of activity at both basic and acidic pH values could be related to pH dependent subunit association equilibrium of the enzyme as it was described for the *E. cloacae* indolepyruvate decarboxylase tetramer structure, which was stabilized in the range of pH 5.6-7.5 (55). The *Ps*BFDC enzyme showed most stability at pH 6.0 which was in the range to that of pH 5.5-7.5 of *Pp*BFDC (12).

The *pI* of the *Ps*BFDC was estimated by denaturing IEF to be 5.2, which was in a good agreement with *pI* calculated from the deduced amino acid sequence. In the previous report, the *pI* of *Pp*BFDC was estimated by native IEF to be 6.5 (12).

Michaelis-Menten parameters were determined for *Ps*BFDC by direct continuous assay under optimal conditions with temperature at 35 °C and pH 6.0. The  $K_m$  value for benzoylformate of 0.69 mM was similar to that for *Pp*BFDC. This was not surprising given that there is 91% sequence identity between the two enzymes, and those changes in sequence are located at some distance from the active site. However, at 222 s<sup>-1</sup> the  $k_{cat}$  value for *Ps*BFDC was 35% lower than that of *Pp*BFDC even though the latter was determined by the coupled assay at a lower temperature (30 °C). Since both *Ps*BFDC and *Pp*BFDC showed high sequence identity, therefore, the differences in  $k_{cat}$  value could be due to the differences in purity of the enzyme used. ThDP-dependent enzymes are often purified as his<sub>6</sub>-tagged variants to avoid loss of activity during multi-step purifications (14, 50). So, to facilitate a more rapid purification, *Ps*BFDC was also prepared with a C-terminal histidine tag, and a homogenous preparation was successfully obtained in a single step. This preparation showed an increase in  $k_{cat}$  to 284 s<sup>-1</sup> and a decrease in  $K_m$  value to 0.43 mM. At 30 °C *Ps*BFDC had both  $K_m$  and  $k_{cat}$  values lower than those of its *P. putida* counterpart although the  $k_{cat}/K_m$  values were virtually identical. Predictably, as suggested by the high sequence

identity, preliminary experiments indicate that the substrate range for *Ps*BFDC is unlikely to be different from that of *Pp*BFDC (data not shown).

## 7. Preparation and purification of histidine-tagged *Ps*BADH

The X-ray structure of the class 3 aldehyde dehydrogenase from rat liver (38) shows that the C-terminal residues interact with other regions of the protein whereas the N-terminal residues are fully accessible. Based on this data an N-terminal histidine tag has been successfully employed to purify *Pp*BADH-his. The kinetic constants for this variant were essentially identical to those of the wt enzyme (C. Yeung and M. McLeish, unpublished results). Given the 86% sequence identity between *Pp*BADH and the putative *Ps*BADH it seemed reasonable to use an N-terminal histidine tag to facilitate the purification of the *dpgC* gene product. Accordingly the *dpgC* gene was amplified from pBCH2 and placed in the expression vector pET19b which adds an N-terminal His<sub>10</sub>-tag. The enzyme was purified in a single step using a nickel affinity column. The purified protein showed a single band on SDS-PAGE with an estimated molecular mass consistent with that calculated from the gene sequence.

As predicted, the enzyme was able to oxidize benzaldehyde using either NAD<sup>+</sup> or NADP<sup>+</sup> as the cofactor. *Ps*BADH prefers NAD<sup>+</sup> over NADP<sup>+</sup> which is similar to both the rat aldehyde dehydrogenase (56) and *Pp*BADH (34). The  $K_m(\text{app})$  values for NAD<sup>+</sup> and NADP<sup>+</sup> were obtained at saturating benzaldehyde concentration and, therefore, are indicative of the true  $K_m$  values. However, for comparison with data for *Pp*BADH (34),  $K_m(\text{app})$  values for benzaldehyde were obtained at 1 mM NAD(P)<sup>+</sup> which is less than saturating. As with *Pp*BADH, it was likely that benzaldehyde was the natural substrate for *Ps*BADH as its apparent  $K_m$  values were in the low micromolar range. Overall, in keeping with their relative sequence identities, the kinetic properties of *Ps*BADH and *Pp*BADH are very similar.

## CHAPTER 6

### CONCLUSION

Firstly, this thesis showed that growth of *Pseudomonas stutzeri* ST-201 on minimal medium (MM) containing D-phenylglycine resulted initially in the induction of D-phenylglycine aminotransferase (D-PhgAT) activity and subsequently in the induction of benzoylformate decarboxylase (BFDC) activity. Conversely, growth of *P. stutzeri* ST-201 on MM containing benzoylformate only induced BFDC activity. The sequential expression of the two enzymes substantiated the role of BFDC from *P. stutzeri* ST-201 (*PsBFDC*) in D-phenylglycine degradation in a step following D-PhgAT. Secondly, this thesis described a strategy used for cloning *dpgB* gene of *PsBFDC*. Not only, the *dpgB* was successfully cloned in one genomic restriction fragment but also the *dpgC* gene of benzaldehyde dehydrogenase (*PsBADH*) was cloned in another overlapped genomic restriction fragment which contained partial *dpgB* gene. Thirdly, this thesis demonstrated the expression of *dpgB* gene in *E. coli*, purification and characterization of the recombinant *PsBFDC*. Finally, this thesis also explained the expression of *dpgC* gene in *E. coli*, purification and characterization of recombinant BADH from *P. stutzeri* ST-201 (*PsBADH*).

The two enzymes share a high degree of sequence identity with the homologous enzymes in the mandelate pathway of *P. putida*. Moreover, their kinetic parameters are similar, suggestive of comparable metabolic roles. It is possible that *PsBFDC* and *PsBADH* are components of the mandelate pathway yet *P. stutzeri* ST-201 is unable to utilize mandelate as a carbon source. Furthermore, the genes are organized quite differently. In *P. putida* ATCC 12633, the gene encoding BFDC (*mdlC*) forms part of an operon with those encoding mandelate racemase (*mdlA*) and S-mandelate dehydrogenase (*mdlB*), while the BADH gene (*mdlD*) is located upstream of the *mdlCBA* operon and is transcribed in the opposite direction. In *P. stutzeri* ST-201, the BFDC gene (*dpgB*) is independently transcribed, and the BADH gene

(*dpgC*) is located downstream of, and transcribed in the same direction as, *dpgB*. Taken together the data suggest that, in combination with D-phenylglycine aminotransferase, the two enzymes form a pathway for the degradation of D-phenylglycine with the product, benzoate, presumably entering the  $\beta$ -ketoacid pathway (6). Whether benzoate is initially converted to 4-hydroxybenzoate or to catechol, and whether subsequent cleavage occurs by the ortho or meta pathway (6, 57), is the subject of future experiments.

## **APPENDIX**

## APPENDIX

### 1. Properties of benzoylformic acid

#### Chemical Names

Benzoylformic acid

Phenylglyoxylic acid

**CAS-No.** 611-73-4

**Chemical Formulae** C<sub>8</sub>H<sub>6</sub>O<sub>3</sub>

**Molecular Weight** 150.13

**Melting Point** 60-69°C

### 2. GenBank Accession No. EF419244 (*Pseudomonas stutzeri* isolate ST-201 benzoylformate decarboxylase (*dpgB*) and benzaldehyde dehydrogenase (*dpgC*) genes, complete cds)

EF419244. Reports \_\_\_ *Pseudomonas stutzeri* [gi:126202186]

LOCUS EF419244 7653 bp DNA linear BCT 09-OCT-2007  
 DEFINITION *Pseudomonas stutzeri* isolate ST-201 benzoylformate decarboxylase (*dpgB*) and benzaldehyde dehydrogenase (*dpgC*) genes, complete cds.

## Abstract

Following induction with D-phenylglycine both D-phenylglycine aminotransferase activity and benzoylformate decarboxylase activity were observed in cultures of *Pseudomonas stutzeri* ST-201. Induction with benzoylformate, on the other hand, induced only benzoylformate decarboxylase activity. Purification of the benzoylformate decarboxylase, followed by N-terminal sequencing, enabled the design of probes for hybridization with *P. stutzeri* ST-201 genomic DNA libraries. Sequencing of two overlapping genomic DNA restriction fragments revealed two open reading frames which were denoted *dpgB* and *dpgC*. Sequence alignments suggested that the genes encoded a thiamin-diphosphate-dependent decarboxylase and an aldehyde dehydrogenase, respectively. Both genes were isolated and expressed in *Escherichia coli*. The *dpgB* gene product was confirmed as a benzoylformate decarboxylase while the *dpgC* gene product was characterized as a NAD<sup>+</sup>/NADP<sup>+</sup>-dependent benzaldehyde dehydrogenase. In keeping with their high sequence identities (both greater than 85%) the kinetic properties of the two enzymes were similar to those of the homologous enzymes in the mandelate pathway of *Pseudomonas putida* ATCC 12633. However, *Pseudomonas stutzeri* ST-201 was unable to grow on either isomer of mandelate, and sequencing indicated that the *dpgB* gene did not form part of an operon. Thus it appears that the two enzymes form part of a D-phenylglycine, rather than mandelate, degrading pathway.

## 1. Introduction

Benzoylformate decarboxylase (BFDC; EC 4.1.1.7) is a thiamin diphosphate (ThDP)-dependent enzyme that catalyzes the decarboxylation of benzoylformate forming benzaldehyde and carbon dioxide [1]. BFDC was initially identified as a member of the mandelate pathway, which enables bacteria to utilize mandelate as a sole carbon source. In this pathway, benzoylformate is formed via the oxidation of *S*-mandelate (Fig. 1) [2–4]. To date, the enzyme has been found in *Pseu-*

*domonas* and *Acinetobacter* species [5,6], as well as *Neurospora crassa* [7], with the most detailed studies being carried out on the BFDC from *Pseudomonas putida* ATCC 12633 (*Pp*BFDC). These include enzyme purification and characterization [3,4], gene cloning [8], kinetic and mechanistic studies [9–11], and X-ray crystallography [12,13]. Over the past few years *Pp*BFDC has become increasingly useful for the synthesis of enantiomerically pure pharmaceutical and chemical compounds [14–16]. Consequently, there is commercial interest in identifying BFDCs with an expanded substrate range whether by protein engineering [17–19] or from alternative sources [20].

Recently, benzoylformate was reported as the product of the reaction catalyzed by a D-phenylglycine aminotransferase

Fig. 1. The mandelate pathway in *P. putida* ATCC 12633 and the proposed pathway for D-phenylglycine degradation in *P. stutzeri* ST-201.

(D-PhgAT) in *Pseudomonas stutzeri* ST-201, a newly isolated soil bacterium found in Thailand [21]. Although *P. stutzeri* ST-201 had not been reported to possess BFDC activity, it had been shown to release both benzoylformate and benzoate into the culture medium during the early stages of D-phenylglycine degradation [21]. Therefore, it was reasonable to hypothesize that this strain could produce both BFDC and benzaldehyde dehydrogenase (BADH) for subsequent metabolism of benzoylformate and benzaldehyde, respectively. Here we confirm the presence of a BFDC in *P. stutzeri* strain ST-201 (*Ps*BFDC) and report the isolation of fragments of *P. stutzeri* ST-201 genomic DNA containing the genes encoding *Ps*BFDC (*dpgB*) and *Ps*BADH (*dpgC*). We describe the expression of *dpgB* and *dpgC* in *Escherichia coli* and the initial characterization of their gene products. Moreover, we suggest that these enzymes form part of a catabolic pathway, which we have termed the D-phenylglycine degradation pathway (Fig. 1).

## 2. Materials and methods

### 2.1. Materials

*P. stutzeri* ST-201 was available from a previous study [21]. *E. coli* strains, restriction enzymes, ligases, DNA polymerase and other molecular biology reagents were obtained from New England Biolabs, Promega, Stratagene or Novagen. All other chemicals were of the highest quality commercially available.

### 2.2. Screening for enzymes involved in mandelate and D-phenylglycine degradation

To verify the existence of enzymes catabolizing substrates of interest, *P. stutzeri* ST-201 was tested for growth on minimal medium (MM) agar containing (in 1 l): 15 g agar, 3.4 g  $\text{KH}_2\text{PO}_4$ , 3.6 g  $\text{Na}_2\text{HPO}_4$ , 0.2 g  $\text{MgSO}_4$ , 8 mg  $\text{CaCl}_2$ , 10 mg yeast extract and 1 ml trace metals solution [22]. The MM was supplemented, as appropriate, with the following carbon sources at a concentration of 10 mM: R-mandelate, S-mandelate, D-phenylglycine, benzoylformate or benzoate. For growth on benzaldehyde, a disk containing benzaldehyde (10  $\mu\text{l}$ ) was placed on the agar. With the exception of MM containing D-phenylglycine, 0.4 g  $\text{NH}_4\text{NO}_3$  was included as the nitrogen source. The plates were examined for evidence of growth after incubation for 48 h at 30 °C.

To explore the induction of D-PhgAT and BFDC activity, *P. stutzeri* ST-201 was shaken in 200 ml Luria-Bertani (LB) medium at 30 °C until the culture reached an  $\text{OD}_{600}$  of 2.8. At that time the LB was exchanged for MM containing one of glucose, D-phenylglycine or benzoylformate (10 mM). Incubation was continued under the same conditions for a further 20–160 min with cell samples being harvested every 20 min. Enzyme activity in crude cell extracts was then determined using standard assays (below).

### 2.3. Purification of wt *Ps*BFDC

*P. stutzeri* ST-201 was grown in LB (2 l) at 30 °C until the culture reached an  $\text{OD}_{600}$  ~2.8. At that time the LB was exchanged for MM containing 10 mM benzoylformate. Shaking continued at 30 °C for 9 h after which time the cells were harvested by centrifugation and the pellet resuspended in a buffer comprising 50 mM potassium phosphate, pH 6.0, 0.1 mM ThDP and 0.1 mM phenylmethylsulfonyl fluoride. Following sonication and centrifugation the cell-free extract (CFE) was subjected to stepwise ammonium sulfate fractionation. The ammonium sulfate fraction containing BFDC was dissolved in buffer A (25 mM potassium phosphate, pH 6.0, 0.1 mM ThDP, 0.1 mM  $\text{MgCl}_2$ , 10% glycerol) and applied to a Phenyl Sepharose FF column which had been equilibrated with buffer B (0.1 M sodium phosphate, pH 6.0 containing 0.1 M  $(\text{NH}_4)_2\text{SO}_4$  and 0.1 mM ThDP). The BFDC was then eluted with buffer B at a flow rate of 2 ml  $\text{min}^{-1}$ . The active fractions were pooled, concentrated and exchanged into buffer C (25 mM Tris-HCl, pH 7.5, 0.1 mM ThDP) using a Centricon Plus-20 filtration unit (Amicon). The concentrate was loaded onto a Q Sepharose FF column equilibrated with buffer C, and the enzyme was eluted with buffer C containing NaCl (0.75 M). After the purity and molecular weight of the active fractions were checked by SDS-PAGE, a sample was blotted onto a polyvinylidene fluoride membrane and subjected to N-terminal sequencing (University of Newcastle, Australia).

### 2.4. Construction of subgenomic library and cloning of the *dpgB* gene

The degenerate forward primer, BFDC\_F (Table 1), was designed based on the N-terminal amino acid sequence of *Ps*BFDC isolated in this work (above). The reverse primer, BFDC\_R, was designed using the conserved amino acid sequences of BFDCs from *P. putida* (gi:3915757) and *P. aeruginosa* PAO1 (gi:15600094). With these primers a 1.28-kb DNA fragment containing part of the *dpgB* gene was amplified by PCR from the genomic DNA of *P. stutzeri* ST-201. The PCR products were cloned into pGEM-T Easy (Promega) and used to generate a digoxigenin-labeled *dpgB*-specific probe for Southern and colony hybridization.

<sup>b</sup> Introduced restriction sites are in bold.

<sup>c</sup> The new *XhoI* site is in bold and the lowercase letters indicate a base change from the wild-type sequence.

For subgenomic library construction, genomic DNA isolated from *P. stutzeri* ST-201 was subjected to digestion with various restriction enzymes, followed by agarose gel electrophoresis and Southern hybridization. Positive DNA fragments were eluted from the gel and ligated into pBluescript II SK which had been digested with the corresponding restriction enzyme(s). The ligation products were transformed into *E. coli* JM109 by electroporation and plated on LB agar containing 50 µg/ml ampicillin, 20 mM isopropyl-β-D-thiogalactopyranoside (IPTG) and 80 µg/ml 5-bromo-4-chloro-3-indolyl-β-D-galactopyranoside (X-gal). White colonies, containing a DNA insert, were screened by colony hybridization to identify individual colonies carrying a plasmid containing the *dpdB* gene. The two plasmids identified in this manner were designated pBCH1 and pBCH2.

### 2.5. DNA sequencing and gene analysis

The nucleotide sequences of both strands of the DNA fragment in pBCH1 and pBCH2 were determined at the National Science and Technology Development Agency, Thailand. The open reading frames (ORFs), DNA and protein alignment were analyzed using either VectorNTI (Invitrogen) or BioEdit (<http://www.mbio.ncsu.edu/BioEdit/bioedit.html>). The nucleotide and deduced amino acid sequences were compared to the sequences in the GenBank and SwissProt databases at the National Center for Biotechnology Information (Bethesda, MD) using the BLAST network server.

The nucleotide sequences determined in this work have been deposited under GeneBank accession no EF419244.

### 2.6. Expression of *P. stutzeri* *dpdB* gene in *E. coli* and purification of recombinant *PsBFDC*

The *dpdB* gene was PCR amplified using pBCH1 as the template. The forward and reverse primers, BFDC\_N and BFDC\_C (Table 1) introduced *NdeI* and *HindIII* sites, respectively. The PCR product was digested with *NdeI* and *HindIII* and ligated into pET17b. The resulting plasmid, pET17b*PsBFDC*, was transformed into *E. coli* strain BL21(DE3). For expression of the recombinant *PsBFDC*, the transformants were grown at 37 °C in LB to an A<sub>600</sub> of 0.8 and induced by the addition of 0.4 mM IPTG. After a 6-h incubation the cells were harvested by centrifugation. Purification of the recombinant *PsBFDC* was accomplished using the protocol described above for the wt enzyme. The purified enzyme, which showed a single band on SDS-PAGE, was stored at 4 °C in a buffer containing 50 mM phosphate, pH 6.0, 0.2 mM ThDP and 0.1 mM MgCl<sub>2</sub>. The protein concentration was determined by the Bradford method using bovine serum albumin as the standard [23].

### 2.7. Expression and purification of histidine-tagged *PsBFDC*

Using pET17b*PsBFDC* as the template, the QuikChange (Stratagene) methodology was employed to introduce an *XhoI* restriction site at the C-terminus of the *dpdB* gene. The sequence of the forward primer, BFDC\_X, is shown in Table 1. The resultant plasmid was digested with *NdeI* and *XhoI* and the 1.6-kb fragment ligated into *NdeI*- and *XhoI*-digested pET24b, to provide a

plasmid, denoted pET24b*PsBFDC*. The fidelity of the mutagenesis was confirmed by sequencing at the University of Michigan core facility.

pET24b*PsBFDC* was transformed into *E. coli* strain BL21(DE3)pLysS (Promega) and a single colony was used to inoculate 50 ml of LB broth containing kanamycin (50 µg/ml) and chloramphenicol (25 µg/ml). This culture was grown overnight at 37 °C and used to inoculate 1 l of fresh medium. The fresh culture was grown at 37 °C until OD<sub>600</sub> reached 0.8. The cells were cooled to 25 °C, and the protein expression was induced by the addition of 1 mM IPTG. The cells were grown for an additional 12 h at 25 °C prior to harvesting by centrifugation. The cell pellet was resuspended in buffer D (50 mM potassium phosphate pH 8.0, 500 mM NaCl, 0.1 mM ThDP) containing 0.1 mM phenylmethanesulfonyl fluoride, disrupted by sonication and the cell debris was removed by centrifugation. The CFE was applied to a HIS-select™ Nickel Affinity column (Sigma) previously equilibrated in buffer D. After the column was washed with buffer D containing 20 mM imidazole, the enzyme was eluted with buffer D containing 250 mM imidazole. The fractions of highest purity, as judged by SDS-PAGE, were pooled and the buffer was exchanged for storage buffer (100 mM potassium phosphate buffer, pH 6.0, 1 mM MgSO<sub>4</sub>, 0.5 mM ThDP, 10% glycerol) using Econo-Pac 10 DG desalting columns (Bio-Rad). The protein was concentrated using Amicon Ultra centrifugal filters (Millipore) before being stored at –20 °C. Protein concentrations were determined by either the Bradford [23] or a UV method [24].

### 2.8. Preparation and purification of histidine-tagged *PsBADH*

Based on the sequence of the open reading frame in pBCH2, two primers were designed to amplify the *dpdB* gene. The forward (BADH\_F) and reverse (BADH\_R) primers (Table 1) added *NdeI* and *XhoI* sites, respectively. Amplification was achieved with *PfuUltra* DNA polymerase (Stratagene), using pBCH2 as the template. The PCR product was purified, digested and ligated into pET19b (Novagen) previously digested with *NdeI* and *XhoI*. This construction added a 10× histidine tag to the N-terminus of the enzyme and generated the expression vector, pET19b*PsBADH*-His. Once the fidelity of the amplification was verified by sequencing, the plasmid was transformed into *E. coli* strain BL21(DE3)pLysS (Promega) for expression.

Expression and preparation of a CFE of his-tagged *PsBADH* were carried out as described for *PsBFDC*-his. The extract was applied on HIS-Select™ Nickel Affinity column previously equilibrated in buffer E (50 mM potassium phosphate buffer, pH 8.0, 300 mM NaCl, 2 mM DTT) containing 10 mM imidazole. After washing with buffer E containing 40 mM imidazole, the enzyme was eluted in buffer E containing 250 mM imidazole. The fractions of highest purity were pooled and the buffer was exchanged for storage buffer (100 mM HEPES pH 7.5, 100 mM KCl, and 2 mM DTT) using Econo-Pac 10 DG desalting columns (Bio-Rad). The *PsBADH*-his was then concentrated using Amicon Ultra centrifugal filters (Millipore) before being stored at –20 °C.

### 2.9. Measurement of enzyme activity

In crude cell extracts, D-PhgAT activity was determined using a spectrophotometric assay in which the rate of benzoylformate formation was measured by monitoring the increase in absorbance at 254 nm [25]. The assay was carried out in a buffer (1 ml) containing Tris-HCl (100 mM, pH 9.0), D-phenylglycine (1 mM), α-ketoglutarate (1 mM), pyridoxal-5'-phosphate (25 µM) and EDTA (25 mM). *BFDC* activity in crude cell extracts was determined using a continuous assay based on the decrease in absorbance at 334 nm as benzoylformate was converted to benzaldehyde [4]. The reaction mixture (1 ml) contained benzoylformate (8.33 mM) and ThDP (40 µM) in sodium phosphate buffer (66 mM, pH 6.0). Both assays were performed at 25 °C.

In addition to the direct method described for the induction studies, the decarboxylation of benzoylformate was also followed using a more sensitive coupled assay [9]. Here the assay was performed at the appropriate temperature in 100 mM potassium phosphate buffer pH 6.0, containing 1.0 mM MgCl<sub>2</sub>, 0.5 mM ThDP, 0.3 mM NADH and 0.25 U/ml of horse liver alcohol dehydrogenase. The benzoylformate concentration was varied from 0.3 to 3× *K<sub>m</sub>* and the reaction was initiated by the addition of *BFDC*. The decrease in absorbance at 340 nm was measured on a Cary 50 spectrophotometer (Varian) equipped with a temperature-controlled cell holder. Initial velocity data were

fitted to the Michaelis–Menten equation using the Enzyme Kinetics module of SigmaPlot® (SPSS Inc.). Kinetic parameters were determined per monomer using molecular masses of 56,302 for *Ps*BFDC or 57,367 for *Ps*BFDC-his.

Benzaldehyde dehydrogenase activity was monitored spectrophotometrically by observing the increase in  $A_{340}$  due to the reduction of  $\text{NAD}^+$  [26]. Routine activity assays were carried out at 25 °C in a 1 ml reaction mixture containing 100 mM TAPS buffer, pH 8.5, 100 mM KCl, 1 mM DTT, 1 mM  $\text{NAD}^+$  and 1 mM benzaldehyde.  $K_m(\text{app})$  values for benzaldehyde were determined by fixing  $\text{NAD}^+$  or  $\text{NADP}^+$  at a concentration of 1 mM and varying the benzaldehyde concentration as required. For determination of the apparent  $K_m$  values for  $\text{NAD}^+$  and  $\text{NADP}^+$ , benzaldehyde was maintained at a saturating concentration (1 mM) and the  $\text{NAD}^+$  or  $\text{NADP}^+$  concentration varied appropriately. Kinetic data were fitted to the Michaelis–Menten equation using the Enzyme Kinetics module of SigmaPlot® (SPSS Inc.). Kinetic parameters were determined per monomer using a molecular mass of 50278 Da for *Ps*BADH-his.

### 3. Results and discussion

#### 3.1. Implication of a benzoylformate decarboxylase in *D*-phenylglycine degradation

With the exception of *R*- and *S*-mandelate, *P. stutzeri* ST-201 was able to grow on MM agar containing each of the tested carbon sources. The results demonstrated that the bacteria could produce enzymes capable of catabolizing *D*-phenylglycine, benzoylformate, benzaldehyde and benzoate. Further, the results showed that *P. stutzeri* ST-201 lacked, at the least, a *S*-mandelate dehydrogenase such as that found in the mandelate pathway of *P. putida* ATCC 12633 (Fig. 1, [3]). Therefore it was reasonable to assume that the benzoylformate found in cultures of *P. stutzeri* ST-201 grown on *D*-phenylglycine [21] was the product of the transamination of *D*-phenylglycine (Fig. 1).

In *P. putida* ATCC 12633 some of the enzymes of the mandelate pathway are coordinately regulated. BFDC activity, for example, can be induced by the addition of either *R*- or *S*-mandelate or benzoylformate (but not benzoate) to the culture medium [3]. In *P. stutzeri* ST-201 neither *D*-PhgAT nor BFDC activity was observed in MM containing glucose. However, when the culture medium was changed from LB to MM containing *D*-phenylglycine, *D*-PhgAT activity was detected after 40 min and was followed by BFDC activity which appeared after 100 min (Fig. 2A). Conversely, in MM with benzoylformate as sole carbon source there was no evidence for *D*-PhgAT activity but BFDC activity was observed after 60 min (Fig. 2B). Clearly, benzoylformate can induce only the expression of the BFDC gene whereas *D*-phenylglycine brings about an increase in the levels of both enzymes. What is not clear is whether this is because *D*-phenylglycine actually induces the genes for both enzymes or whether the gene for *D*-PhgAT is induced and the benzoylformate subsequently produced induces the BFDC gene. Based on the times at which the two enzyme activities are observed the latter is the most likely explanation. Regardless, the sequential expression of the enzymes substantiates the involvement of BFDC in the pathway in a step following *D*-phenylglycine degradation.

The decrease in the absorbance due to benzoylformate, as well as the presence of the characteristic odor of benzaldehyde, in the BFDC assays both pointed to the *P. stutzeri* ST-201 extracts having BFDC activity. Nevertheless, the presence of a

Fig. 2. Time course for the appearance of *D*-phenylglycine aminotransferase (O) and benzoylformate decarboxylase (■) activity. At  $t=0$  the culture of *P. stutzeri* ST-201 was changed to a minimal medium containing either (A) *D*-phenylglycine or (B) benzoylformate at a concentration of 10 mM. Enzyme activity was measured as described in Materials and methods and normalized to activity at  $t=160$  min.

*Ps*BFDC could only be confirmed by purification of the enzyme. This was achieved in a series of steps including ammonium sulfate fractionation, followed by hydrophobic and ion-exchange chromatography. SDS-PAGE analysis suggested a molecular weight of ~55 kDa. Sequencing of the purified enzyme provided an N-terminal sequence of ASVHSI-TYELLRRQGIDTVFGNP which was employed to generate primers (Table 1) for use in hybridization experiments.

#### 3.2. Construction of subgenomic library and identification of the *dpgB* and *dpgC* genes

Southern hybridization of *P. stutzeri* ST-201 genomic DNA which had been digested with *Eco*RI and *Hind*III gave a positive band of ca. 5–7 kb. A subgenomic DNA library was constructed and, of 400 recombinant clones, one was positive to colony hybridization. That clone carried a plasmid with a 6-kb insert which was designated as pBCH1. Sequencing of pBCH1 revealed an open reading frame (ORF) of 1581 bp which was denoted *dpgB*, and which encoded a protein of 526 amino acids with a deduced molecular mass of 56 kDa. This was in good agreement with the 55 kDa observed on SDS-PAGE for the BFDC purified from induced *P. stutzeri* ST-201 cells. In addition, the deduced amino acid sequence of the N-terminal 23

amino acids of *dpgB* was identical to that of the native *Ps*BFDC lacking the N-terminal methionine.

BLASTp analysis of the deduced amino acid sequence of *dpgB* revealed significant homology to other bacterial benzoylformate decarboxylases, with the highest sequence identity being 91% to *Pp*BFDC (gi:3915757). Those active site residues implicated in the catalytic mechanism of *Pp*BFDC, including Ser26, Glu47, His70 and His281 [11], were all conserved. Analysis of the DNA sequence upstream of *dpgB* identified a putative ribosome binding site and  $-10$  and  $-35$  promoter regions. No ORFs were identified in the 300-bp sequence upstream from *dpgB* while downstream of the ORF a putative  $\rho$ -independent transcriptional terminator was also identified (data not shown). In addition a partial ORF was identified about 250 bp downstream of *dpgB* (Fig. 3A). Overall these results suggested that *dpgB* was transcribed monocistronically, unlike the gene encoding *Pp*BFDC which was arranged and transcribed in the *mdlCBA* operon (Fig. 3B) [8].

In addition to the *EcoRI*–*HindIII* digests described above, Southern hybridization of *P. stutzeri* ST-201 genomic DNA digested with *PstI* also gave a positive band. Colony hybridization with a second subgenomic library identified a clone carrying a plasmid with a 4-kb insert. This plasmid was designated as pBCH2. Sequencing of pBCH2 identified a region which corresponded to part of the *dpgB* gene. However, this insert also carried the full-length ORF of 1311 bp downstream of *dpgB*. The ORF, denoted *dpgC*, was transcribed in the same direction as *dpgB* and encoded a protein of 436 amino acids with a deduced molecular mass of 47.7 kDa.

The evidence for BFDC activity coupled with the observations that *P. stutzeri* ST-201 was able to grow on benzaldehyde

Fig. 3. (A) Restriction fragment of the genomic DNA from *P. stutzeri* ST-201 carrying the genes for benzoylformate decarboxylase (*dpgB*) and benzaldehyde dehydrogenase (*dpgC*). The fragment (7.65 kb) shown is the combination of two overlapping genomic DNA fragments contained in pBCH1 and pBCH2. The arrows show the position and orientation of the genes, and relevant restriction sites are indicated. The sequence of the combined fragment has been deposited under GeneBank accession no. EF419244. (B) Organization of the mandelate pathway genes based on GeneBank accession no. AY143338. Benzoylformate decarboxylase (*mdlC*), *S*-mandelate dehydrogenase (*mdlB*) and mandelate racemase (*mdlA*) make up the *mdlCBA* operon while benzaldehyde dehydrogenase (*mdlD*) is transcribed independently.

Fig. 4. SDS-PAGE analysis of the recombinant *Ps*BFDC during the purification process. Lanes: M, molecular mass standards (kDa); 1, crude cell lysate; 2, 45–65% ammonium sulfate fraction; 3, following phenyl sepharose chromatography; 4, following ultrafiltration; 5, following Q-Sepharose chromatography.

and that benzoate could be found in the culture medium suggested the likely presence of a BADH. Consequently, it was not surprising when a BLAST search of the full-length amino acid sequence indicated that the *dpgC* gene product was likely to be an aldehyde dehydrogenase, probably of the class 3 type. Dehydrogenases of this class are characterized by the ability to utilize both  $\text{NAD}^+$  and  $\text{NADP}^+$  [27]. The sequence was 86% identical to that of the BADH from *P. putida* ATCC 12633 [26]. The catalytic residues, including the catalytic thiol (Cys249) and the general base (Glu337), were conserved as was the aspartic acid residue (Asp253) that links conserved domains in class 3 aldehyde dehydrogenases [28]. *Ps*BADH also shared 30–40% sequence identity with other aldehyde dehydrogenases from pseudomonads, including the *p*-hydroxybenzaldehyde dehydrogenase from *P. putida* NCIMB 9866 [29]. However, although they are closely related phylogenetically, the other pseudomonad aldehyde dehydrogenases are not class 3 enzymes [27].

### 3.3. Expression and purification of recombinant *Ps*BFDC

BFDC activity was found in the CFE from IPTG-induced *E. coli* BL21 (DE3) harboring the plasmid pET17b*Ps*BFDC. The majority of the BFDC activity precipitated at 45–65% ammonium sulfate saturation. As shown in Fig. 4, following hydrophobic interaction chromatography, ultrafiltration and ion-exchange chromatography, the enzyme ran as a single band by SDS-PAGE analysis.

The molecular mass of the recombinant enzyme, ~56 kDa, was in good agreement with the molecular mass calculated from the *dpgB* gene sequence. Gel-filtration experiments provided a native molecular mass of ~220 kDa (data not shown). This indicated that BFDC from *P. stutzeri* ST-201 associates as a homotetramer, a characteristic common in bacterial BFDCs [5,13]. The enzyme showed maximum activity at 35–50 °C and at pH 6.0 (data not shown) which was similar to results for the BFDCs from *N. crassa* [7] and *P. putida* [4], respectively.

Michaelis–Menten parameters were determined for *Ps*BFDC under optimal conditions (35 °C and pH 6.0, Table 2). The  $K_m$  value for benzoylformate of 0.69 mM was similar to

Table 2  
Kinetic parameters for *Ps*BFDC<sup>a</sup>

Enzyme	Temperature (°C)	$K_m$ (mM)	$k_{cat}$ (s <sup>-1</sup> )	$k_{cat}/K_m$ (s <sup>-1</sup> M <sup>-1</sup> )
wt <i>Ps</i> BFDC	35	0.69±0.10	222±3	3.2×10 <sup>5</sup>
<i>Ps</i> BFDC-his	35	0.44±0.07	284±12	6.4×10 <sup>5</sup>
<i>Ps</i> BFDC-his	30	0.43±0.05	213±7	5.0×10 <sup>5</sup>
<i>Pp</i> BFDC-his <sup>b</sup>	30	0.54±0.05	342±13	6.3×10 <sup>5</sup>

<sup>a</sup> Experiments were carried out at pH 6.0 as described in Materials and methods.

<sup>b</sup> Data from Linggen et al. [17].

Table 3  
Kinetic parameters for *Ps*BADH<sup>a</sup>

Variable substrate	Fixed substrate <sup>b</sup>	$K_m$ (app) (μM)	$k_{cat}$ (s <sup>-1</sup> )	$k_{cat}/K_m$ (s <sup>-1</sup> M <sup>-1</sup> )
Benzaldehyde	NAD <sup>+</sup>	7.1±0.6	57±8	8.0×10 <sup>6</sup>
Benzaldehyde	NADP <sup>+</sup>	6.9±0.4	6.4±0.4	9.3×10 <sup>5</sup>
NAD <sup>+</sup>	Benzaldehyde	997±111	176±9	1.8×10 <sup>5</sup>
NADP <sup>+</sup>	Benzaldehyde	6140±375	40±3	6.5×10 <sup>3</sup>

<sup>a</sup> Experiments were carried out at 25 °C and pH 8.5 as described in Materials and methods. The data are the mean of at least 3 individual experiments and are reported as ±S.D.

<sup>b</sup> Concentration of the fixed substrate was maintained at 1 mM.

that for *Pp*BFDC which was not surprising given that there is 91% sequence identity between the two enzymes, and those changes in sequence are located at some distance from the active site. However, at 222 s<sup>-1</sup> the  $k_{cat}$  value for *Ps*BFDC was 35% lower than that of *Pp*BFDC even though the latter was determined at a lower temperature (30 °C). ThDP-dependent enzymes are often purified as his<sub>6</sub>-tagged variants to avoid loss of activity during multi-step purifications [14,30]. So, to facilitate a more rapid purification, *Ps*BFDC was also prepared with a C-terminal histidine tag, and a homogenous preparation was obtained in a single step (Fig. 5A). This preparation showed an increase in  $k_{cat}$  to 284 s<sup>-1</sup> and a decrease in  $K_m$  value to 0.43 mM. At 30 °C *Ps*BFDC had both  $K_m$  and  $k_{cat}$  values lower than those of its *P. putida* counterpart although the  $k_{cat}/K_m$  values were virtually identical (Table 2). Predictably, as suggested by the high sequence identity, preliminary experiments indicate that the substrate range for *Ps*BFDC is unlikely to be different from that of *Pp*BFDC (data not shown).

### 3.4. Cloning, expression, purification and characterization of benzaldehyde dehydrogenase

The X-ray structure of the class 3 aldehyde dehydrogenase from rat liver [31] shows that the C-terminal residues interact

Fig. 5. Single step purification of (A) *Ps*BFDC-his and (B) *Ps*BADH-his. In each case the lanes are: M, molecular mass standards (kDa); 1, crude cell lysate; 2, after His-Select nickel affinity chromatography.

with other regions of the protein whereas the N-terminal residues are fully accessible. Based on these data a N-terminal histidine tag has been successfully employed in this laboratory to purify *Pp*BADH-his. The kinetic constants for this variant were essentially identical to those of the wt enzyme (C. Yeung and M. McLeish, unpublished results). Given the 86% sequence identity between *Pp*BADH and the putative *Ps*BADH it seemed reasonable to use a N-terminal histidine tag to facilitate the purification of the *dpgC* gene product. Accordingly the *dpgC* gene was amplified from pBCH2 and placed in the expression vector pET19b which adds an N-terminal His<sub>10</sub>-tag. The enzyme was purified in a single step using a nickel affinity column. The purified protein showed a single band on SDS-PAGE with an estimated molecular mass consistent with that calculated from the gene sequence (Fig. 5B).

As predicted, the enzyme was able to oxidize benzaldehyde using either NAD<sup>+</sup> or NADP<sup>+</sup> as the cofactor. *Ps*BADH prefers NAD<sup>+</sup> over NADP<sup>+</sup> which is similar to both the rat aldehyde dehydrogenase [32] and *Pp*BADH [26]. The  $K_m$ (app) values for NAD<sup>+</sup> and NADP<sup>+</sup> were obtained at saturating benzaldehyde concentration and, therefore, are indicative of the true  $K_m$  values. However, for comparison with data for *Pp*BADH [26],  $K_m$ (app) values for benzaldehyde were obtained at 1 mM NAD (P)<sup>+</sup> which is less than saturating. As with *Pp*BADH, it was likely that benzaldehyde was the natural substrate for *Ps*BADH as its apparent  $K_m$  values were in the low micromolar range (Table 3). Overall, in keeping with their relative sequence identities, the kinetic properties of *Ps*BADH and *Pp*BADH are very similar.

## 4. Conclusions

We have shown that growth of *P. stutzeri* ST-201 on D-phenylglycine results initially in the induction of D-PhgAT and subsequently in the induction of BFDC. Conversely, benzoylformate is only able to induce BFDC. We have cloned and sequenced the *dpgB* and *dpgC* genes and characterized the gene products as a BFDC and a BADH, respectively. The two enzymes share a high degree of sequence identity with the homologous enzymes in the mandelate pathway of *P. putida*. Moreover, their kinetic parameters are similar, suggestive of comparable metabolic roles. It is possible that *Ps*BFDC and *Ps*BADH are components of the mandelate pathway yet *P. stutzeri* ST-201 is unable to utilize mandelate as a carbon

source. Further the genes are organized quite differently. In *P. putida* ATCC 12633, the gene encoding BFDC (*mdlC*) forms part of an operon with those encoding mandelate racemase (*mdlA*) and *S*-mandelate dehydrogenase (*mdlB*), while the BADH gene (*mdlD*) is located upstream of the *mdlCBA* operon and is transcribed in the opposite direction. In *P. stutzeri* ST-201, the BFDC gene (*dpgB*) is independently transcribed, and the BADH gene (*dpgC*) is located downstream of, and transcribed in the same direction as, *dpgB*. Taken together the data suggest that, in combination with D-phenylglycine aminotransferase, the two enzymes form a pathway for the degradation of D-phenylglycine with the product, benzoate, presumably entering the  $\beta$ -ketoacid pathway [6]. Whether benzoate is initially converted to 4-hydroxybenzoate or to catechol, and whether the subsequent cleavage occurs by the ortho or meta pathway [6,33], is the subject of ongoing experiments.

## BIOGRAPHY

<b>NAME</b>	Mr. Choedchai Saehuan
<b>DATE OF BIRTH</b>	May 14, 1967
<b>PLACE OF BIRTH</b>	Uttaradit, Thailand
<b>INSTITUTIONS ATTENDED</b>	Chiangmai University, 1985-1988: Bachelor of Science (Medical Technology) (First Class Honor) Mahidol University, 2000-2007: Doctor of Philosophy (Microbiology)
<b>HOME -ADDRESS</b>	202, Moo 3, Mahatart Road, Tumbol Naimuang, Amphur Pichai, Uttaradit, Thailand 53120
<b>SCHOLARSHIPS</b>	- Institutional Strengthening Programme, Faculty of Science, Mahidol University, 2000-2002 - Thesis Scholarship, The Commission on Higher Education and Faculty of Graduate Studies, Mahidol University, 2004 - Royal Golden Jubilee Ph.D. Programme, Thailand Research Fund, 2005-2007
<b>PUBLICATION</b>
