ACKNOWLEDGEMENTS

I would like to express my deepest gratitude to my major advisor, Lect. Puangpen Tangboonduangjit for her very valuable advice, guidance, supervision, constructive comments and patience throughout this thesis. I am grateful to Lect. Nuanpen Damrongkijudom for her important suggestions and comments.

I would also like to thank Medical physicists, Ms. Siwaporn Sakulsingharoj and Ms. Supaporn Srisuwan for their great assistance and training of the techniques through the TLD calibration and TLD reading process. I would also like to show my appreciation to Ms. Pimolpun Changkaew for her training of the use computerized treatment planning system both Eclipse and Pinnacle, and the assistance in ClinaciX using through the irradiation process.

I am grateful to the department of Therapeutic Radiology, Ramathibodi Hospital for allowing in equipment for this experiment. I wish to thank all teachers, lecturers, my classmates and staffs in the School of Medical Physics, Ramathibodi Hospital, Mahidol University for their kind support throughout the entire course of study.

Finally, I am deeply grateful to my family for their financial support, entirely care, and love. The usefulness of this thesis, I dedicate to my family and all teachers who have taught me since my childhood.

COMPARISON OF BUILD-UP REGION DOSES IN OBLIQUE TANGENTIAL 6 MV PHOTON BEAMS CALCULATED BY AAA AND CCC ALGORITHMS IN BREAST RANDO PHANTOM**PONGAPISIT MASUNUN 5436421 RAMP/M****M.SC. (MEDICAL PHYSICS)****THESIS ADVISORY COMMITTEE: PUANGPEN TANGBOONDUANGJIT, Ph.D.,
NUANPEN DAMRONGKIJUDOM, Ph.D.****ABSTRACT**

The purpose of this study was to compare the build-up region doses on breast Rando phantom surface with the bolus covered, the doses in breast Rando phantom and also the doses in lung that is the heterogeneous region by two algorithms.

The analytical anisotropic algorithm (AAA) version 8.9 in Eclipse treatment planning system and the collapsed cone convolution (CCC) algorithm version 9.2 in Pinnacle treatment planning system were used to plan in tangential field technique with 6 MV photon beam at 200 cGy total doses in breast Rando phantom with bolus covered (5 mm and 10 mm). Thermoluminescent dosimeters (TLDs) were calibrated with Cobalt-60 and used to measure the doses in irradiation process.

The results in treatment planning showed that the doses in build-up region, the doses in breast phantom and the doses in lung (point L1) were closely matched in both algorithms and both thicknesses of bolus which were less than 2% different. The planning doses in build-up region, breast Rando phantom and lung (point L1) were overestimated in both thicknesses of bolus and both algorithm when compared with irradiated dose except in the lung (point L2) that was a point of beam edges region.

Above all, the TLD measurements showed that CCC algorithm performed better when compared with AAA algorithm at both thicknesses of bolus. However, uncertainties in measurement may occur through the process of placing bolus over the curve of breast Rando phantom which creates an air gap between bolus and surface of the phantom. Further study might be required in other detectors or other techniques to have more evidence to illustrate the accuracy of dose calculation in buildup region and in lung tissue from the algorithms.

บทคัดย่อ

การศึกษานี้มีวัตถุประสงค์เพื่อต้องการเปรียบเทียบปริมาณรังสีบริเวณบิลด์อัปบนเรนโดแฟนทอมส่วนเต้านมที่มีโบลัสต์คลุ่มอยู่ ปริมาณรังสีในเรนโดแฟนทอมส่วนเต้านมและปริมาณรังสีในบริเวณปอด โดยเปรียบเทียบการคำนวณปริมาณรังสีด้วยอัลกอริทึมสองชนิด ได้แก่ อัลกอริทึม AAA ในระบบวางแผนการรักษาของ Eclipse เวอร์ชัน 8.9 และอัลกอริทึม CCC ในระบบวางแผนการรักษาของ Pinnacle เวอร์ชัน 8.9 ซึ่งทำการวางแผนการฉายรังสีโฟตอนพลังงาน 6 เมกะโวลต์ ด้วยเทคนิคแบบมุมเฉียง และให้ปริมาณรังสี 200 เซ็นติเกรย์ ในเรนโดแฟนทอมที่มีโบลัสต์คลุ่มอยู่ 5 และ 10 มิลลิเมตร อีกทั้งยังมีการวัดปริมาณรังสีที่ได้รับจริงโดยใช้ทีแอลดี (TLD) ซึ่งเป็นตัววัดรังสีชนิดหนึ่งที่มีการสอบเทียบความถูกต้องในการนับวัดรังสีด้วยเครื่องโคบอลต์-60

ผลการศึกษาพบว่า ทั้งสองอัลกอริทึมสามารถคำนวณปริมาณรังสีบริเวณบิลด์อัปบนเรนโดแฟนทอมส่วนเต้านมที่มีโบลัสต์คลุ่มอยู่ ปริมาณรังสีในเรนโดแฟนทอมส่วนเต้านมและปริมาณรังสีในบริเวณปอด (จุด L1) ได้ใกล้เคียงกันที่โบลัสต์ 5 และ 10 มิลลิเมตร โดยมีค่าความแตกต่างกันน้อยกว่า 2% ยกเว้นบริเวณปอด (จุด L2) ซึ่งมีค่าความแตกต่างมากกว่า 2% และจากการวัดปริมาณรังสีจริงด้วยทีแอลดีพบว่า ปริมาณรังสีบริเวณบิลด์อัปบนเรนโดแฟนทอมส่วนเต้านมที่มีโบลัสต์คลุ่มอยู่ ปริมาณรังสีในเรนโดแฟนทอมส่วนเต้านมและปริมาณรังสีบริเวณปอด (จุด L1) ได้ค่าปริมาณรังสีที่น้อยกว่าเมื่อเปรียบเทียบกับปริมาณรังสีที่ได้การคำนวณด้วยอัลกอริทึมทั้งสองชนิดในระบบวางแผนการรักษา ยกเว้นบริเวณปอด (จุด L2) ซึ่งมีคลาดเคลื่อนสูงในการวัดปริมาณรังสี เนื่องจากเป็นบริเวณของขอบลำรังสี

จากการศึกษาโดยรวมแล้วพบว่า อัลกอริทึม CCC สามารถที่จะคำนวณปริมาณรังสีในแผนการรักษาได้ใกล้เคียงกับการวัดจริงด้วยตัววัดทีแอลดีมากกว่าอัลกอริทึม AAA แต่อย่างไรก็ตาม การศึกษาในครั้งนี้ยังมีข้อผิดพลาดบางประการที่อาจทำให้เกิดความคลาดเคลื่อนในการวัดปริมาณรังสี โดยการวางแผนโบลัสต์ลงบนเรนโดแฟนทอมส่วนเต้านมนั้น ไม่สามารถทำให้แผ่นโบลัสต์แนบสนิทชิดกับเรนโดแฟนทอม จึงทำให้เกิดช่องว่างและมีอากาศอยู่ในบริเวณนั้น ทำให้ปริมาณรังสีในบริเวณดังกล่าวคลาดเคลื่อนไป และหากมีการศึกษาครั้งต่อไป ควรจะมีการนำเครื่องวัดปริมาณรังสีชนิดอื่นหรือเทคนิคอื่นๆเข้ามาประยุกต์ใช้ เพื่อความถูกต้องแม่นยำในการวัดและคำนวณปริมาณรังสีบริเวณดังกล่าว

CHAPTER I

INTRODUCTION

Radiation is currently important in the medical field that used for diagnostic and treating the patients, especially in cancer patients. The delivered radiation doses to the patients must be precise, accurate and appropriate for the local of any type of cancer. The evaluation of delivered doses on surface area, in build-up region or in the heterogeneous medium is quite uncertain due to the algorithm calculation that may cause the effect directly to the patients such as erythema and hyperpigmentation. Too low doses from the uncertain calculation are insufficient to damage the gross tumor or too high doses are over limited for curing cancer and affected to the result of treatment.

Nowadays, new technologies of treatment machines are developed due to the complex of planning and treatment. Dose calculation algorithms are influential and controlled the accuracy of radiation doses in treatment planning process. In all superposition/convolution methods, the analytical anisotropic algorithm (AAA) and the collapsed cone convolution algorithm (CCC) are popular because of the accuracy in heterogeneous media calculation, especially in the lung. However, both algorithms can not well predict the surface doses and build-up region doses in solid water phantom shown by the study of Chow et al [1]. On the other hand, the study by Hasenbalg et al [2] have shown that CCC algorithm performed overall better than AAA algorithm compared to Monte Carlo in clinical cases of lung and breast.

Mostly irradiation treatment in breast cancer case is oblique tangential photon beam technique. The prediction of surface doses variation for the tangential like photon beams are extremely caution in radiation therapy. Chow and Grigorov [3] have shown that the relative dose profile in the phantom skin did not change with oblique beam using full phantom geometry. Nevertheless, the surface relative depth dose was increased for half phantom geometry (phantom-air interface) like the breast. Above all, in this study is to compare the build-up region doses on breast Rando phantom surface with the bolus covered, the doses in breast Rando phantom and also

the doses in lung by two algorithms which are analytical anisotropic algorithm and collapsed cone convolution algorithm.

Above all, the treatment planning was used and predicted the radiation doses from both algorithms calculation. However, the actual radiation doses should be measured directly by the suitable dosimeter for comparing the difference of estimated doses and measured doses. The suitable dosimeter was thermoluminescent dosimeters (TLDs) that calibrated with Cobalt-60 and used to measure the doses in irradiation process.

CHAPTER II

OBJECTIVE

The main objectives of this study are to compare the build-up region doses on breast Rando phantom surface with the bolus covered, the doses in breast Rando phantom and also the doses in lung by AAA and CCC algorithms. The sub-objective is to study that which algorithm is calculated closer to the direct measurement by thermoluminescent dosimeter (TLD).

CHAPTER III

LITERATURE REVIEWS

3.1 Basic knowledge

3.1.1 Build-up region

The build-up region is a region between the surface and the depth of maximum dose where the high dose gradient rapidly increased. The result of build-up region dose is called “skin sparing effect”. The build-up region is comprised of the primary photon beam, backscattered radiation from the patient and contamination electron.

3.1.2 Thermoluminescent dosimeter

Thermoluminescent dosimetry (TLD) is based on the ability of certain imperfect crystals to absorb and store the energy of ionizing radiation, upon heating, is re-emitted in the form of light. The light is detected and the light output is correlated to the absorbed dose. TLD are generated naturally or by doping phosphors with a very small percentage of activators (LiF:Mg-Ti is lithium fluoride doped with magnesium and titanium, $\text{Li}_2\text{B}_4\text{O}_7\text{:Cu}$ is lithium borate doped with copper, etc.). They are available in the form of power, solid dosimeters made of polycrystalline extrusions (rods, sintered pellets or chips) or powder bonded to a polypropylene and plastic substrate. TLD can be used for in-vivo dose measurement in external radiotherapy and brachytherapy.

3.1.3 Tangential field technique in breast radiotherapy

The breast or chest wall is treated isocentrically and covered by a pair of opposing tangential fields. The posterior beam edges are parallel to reduce divergence into the lung. The whole breast is included to ensure any residual or microscopic disease is irradiated. Field border is shown in Table 3.1.

Table 3.1 Field border of tangential field technique.

Field border	Anatomical landmark
Superior border	Suprasternal notch
Inferior border	2 cm lower from the scar
Medial border	Anatomical midline
Lateral border	Midaxillary line

3.1.4 Analytical Anisotropic Algorithm (AAA)

The AAA is a 3D pencil beam convolution/superposition algorithm and implemented in the Eclipse treatment planning system. Monte Carlo is used to characterize the clinical beam and to model the basic physical parameter needed. The AAA calculation model consists of two components, the configuration and the actual dose calculation algorithm.

The configuration module is used to characterize the phase space of clinical beam. The phase space is done by a multiple source model consisting of a primary photon beam, extra focal photon source and electron contamination source.

The dose calculation module is divided into two parts. The first part is made as if the patient were a water equivalent medium. Firstly, the monoenergetic kernels in every beamlet are superpositioned to form polyenergetic pencil beam kernels for every voxel along the fanline. Then, the calculation model is separated the energy deposition along the fanline and perpendicular to the fanline. To account for the heterogeneous medium a correction is made scaled locally with the inverse relative electron density. The second part, electron contamination is modeled with a depth-dependence curve that describes the total amount of electron contamination dose at a certain depth. Electron contamination is used to model the photon contamination.

3.1.5 Collapse Cone Convolution (CCC)

The CCC method uses an analytical kernel represented by a set of cones, the energy deposited in which is collapse into a line. The CCC algorithm determines the total energy released per unit mass (TERMA) in a 3D matrix of the irradiated volume, based on the ray-tracing technique. The TERMA contained two parts namely, the primary and scatter part. The dose in a voxel of irradiated volume is determined by

convolving the point kernel with the TERMA distribution. Contaminated electron entering to phantom in the build-up region that modeled by using an exponential function. This contaminated electron dose is added to the photon dose.

3.2 AAA and CCC calculations in treatment planning

Chow et al [1] studied the evaluation of dose calculation in tangential photon beam by AAA and CCC algorithms compared with Monte Carlo in a solid water phantom. The photon beams of 6 and 15 MV with field sizes 4×4, 10×10 and 20×20 cm² with gantry rotated in 5° and 45° anti-clockwise were used in this study and vertical dose profiles at a distance of 2 mm from the phantom lateral skin (skin slab) was calculated. The results in the gantry 0° were found that both AAA and CCC overestimated doses in the phantom skin profile compared to Monte Carlo. For oblique photon beam at 5°, the mean doses in skin slab were underestimated in both AAA and CCC when compared with Monte Carlo. However, the mean doses in skin slab were overestimated in both AAA and CCC in oblique photon beam at 45°. This study was found that both AAA and CCC cannot predict doses reliably at depth shallower than 2 mm which is related to surface doses.

Hasenbalg et al [2] studied the difference doses of AAA and CCC calculations in clinical cases when compared with Monte Carlo. Five clinical cases were studied: three lung and two breast cases. Each clinical case was calculated in AAA, CCC and Monte Carlo. The planning target volume (PTV) coverage in each clinical case was found and compared. The results showed that CCC algorithm performed overall better than AAA compared to Monte Carlo, but AAA remains an attractive option for routine use in the clinic due to its short computation times. Dose difference between the difference algorithms for the median value of the PTV were typically 0.4% in the lung and -1.3% in the breast.

3.3 Surface dosimetry

Chow and Grigorov [3] studied the effect of beam obliquity on the surface dose profiles for tangential photon beams. The 6 and 15 MV photon beams with

10×10 cm² field sizes produced by a Varian 21 EX linear accelerator were used. Monte Carlo simulations were created base on the EGSnrc code and verified with film measurement. Firstly, the relative dose profiles in the phantom skin (2 mm depth from the surface) of the half phantom geometry (HPG) were calculated for increasing gantry angles from 270° to 280° clockwise. The results showed that when the beam angle starting from 270° to 273°, was increased from 1° to 3°, the relative depth doses in phantom skin were increased from 68% to 79% and 81% to 87% at 10 cm depth with 6 and 15 MV photon beams, respectively. After that, the relative dose profile of full phantom enclosing the whole tangential beam (full phantom geometry, or FPG) were also calculated with Monte Carlo for increasing gantry angles from 270° to 280° clockwise. The results showed that the relative dose profiles in the phantom skin did not change significantly with an oblique tangential beam. In this study shown the relative depth doses were sensitive increased to the beam obliquity for the HPG or phantom-air interface medium. The prediction of surface relative dose variation for tangential beam should be cautions in radiation therapy.

The study of Alashrah et al [4] was to investigate the dose at the surface of a water phantom at depth of 0.007 cm as a recommended by the International Commission on Radiological Protection and International Commission on Radiation Units and Measurement by using radiochromic films (Gafchromic MD-55 film), thermoluminescent dosimeters (TLD-100 chip) and ionization chamber (PTW 0.6-cm³ Farmer chamber) in a 6-MV photon beam. The results were compared with the calculation using the Monte Carlo simulation software (MCNP5, BEAMnrc and DOSXYZnrc). The percent surface dose (PSD) was 15.0 ± 3.6%, 16.0 ± 5.0% and 50.0 ± 3.0% for radiochromic films, TLDs and ionisation chamber, respectively. The calculation using MCNP5 and DOSXYZnrc yielded a percent surface dose of 15.0 ± 2.0% and 15.7 ± 2.2%. The results showed good agreement between using radiochromic film and TLDs with the Monte Carlo simulation. However, the cylindrical ionisation was overestimated of the percent surface dose when compared with both Monte Carlo simulations.

Wong et al [5] studied the accuracy of surface dose calculation by a clinically using treatment planning system and measurement by thermoluminescent dosimeters in a customized chest wall phantom. A CMS Xio 3D treatment planning

system (Elekta CMS Software, Stockholm, Sweden) was used to calculate the seven points doses that were placed throughout each right chest wall phantom and were measured by thermoluminescent dosimeters (LiF chips). The results showed that there was no significant difference between measured doses (TLDs) and calculated doses (TPS). Dose accuracy of up to 2.21% was obtained.

CHAPTER IV

MATERIALS AND METHODS

4.1 Materials

4.1.1 Linear accelerator

ClinaciX linear accelerator which manufactured by Varian Oncology Systems, Palo Alto, California, USA was used in this study as shown in Figure 4.1. This machine is dual photon beam energies as 6 and 10 MV, the field size can be changed from 0.3 x 0.3 cm² to 40 x 40 cm² at 100 cm source to surface distance. The machine can also generate five electron beam energies as 6 MeV, 9 MeV, 12MeV, 16 MeV and 20 MeV. The dose rate ranges from 100 - 600 monitor units per minute. The MLCs are 120 leafs Millenium with of tungsten-alloy composition.

Figure 4.1 The Varian ClinaciX linear accelerator.

4.1.2 Treatment planning system

The analytical anisotropic algorithm (AAA) version 8.9 available in Eclipse treatment planning system (Varian, Palo Alto, California, USA) and the

collapsed cone convolution algorithm (CCC) version 9.2 available in Pinnacle treatment planning system (Philips, Fitchburg, Wisconsin, USA) were used for planning and calculation in this study.

4.1.3 CT simulator

The GE Optima CT580 Healthcare CT 16 slices (General Electric Healthcare, Milwaukee, Wisconsin, USA) with spiral computed tomography system was used to scan the slice images of the phantom as shown in Figure 4.2. The gantry aperture diameter is 80 cm but the true size scan field is 60 cm.

Figure 4.2 The GE Optima CT580 Healthcare in Ramathibodi Hospital.

4.1.4 Rando phantom

The Alderson Rando phantom (RSD, Long beach, California, USA) is an invaluable aid in radiotherapy treatment planning. The soft tissue material is manufactured with a proprietary urethane formulation and has an elective atomic number and mass density which simulates muscle tissue which randomly distributed fat. The lung material has the same elective atomic number and mass density which simulates lungs in a median respiratory state. The Rando phantom is sliced at 2.5 cm thicknesses and 3 cm thick sections for only breast part. Each phantom section is hole grid pattern and can be inserted the TLD into its. The Alderson Rando phantom with right breast is shown in Figure 4.3.

Figure 4.3 The Alderson Rando phantom.

4.1.5 Thermoluminescent dosimeter

4.1.5.1 Thermoluminescent dosimeter type 100 rods

TLD-100 rods is made from Lithium Fluoride (Li natural) doped with magnesium and titanium (LiF:Mg,Ti) that manufactured by Harshaw Chemical Company, Cleveland, Ohio, USA. The measurement ranges are 10 pGy to 10 Gy. The diameter is 1 mm and 5 mm length.

4.1.5.2 Thermoluminescent reader

The TLD annealing oven (PTW-TLDO) was used to heat the TLDs before and after reading. HARSHAW TLD Model 5500 Automatic Reader was used by inserted the planchet that consists 50 rods maximum and controlled by WinREMS program. The TLD annealing oven and TLD Reader is shown in Figure 4.4.

Figure 4.4 The TLD annealing oven (left) and TLD Reader (right).

4.1.6 Superflab bolus material

Superflab bolus is made from synthetic oil gel that has a specific gravity of 1.02. It is a tissue equivalent sheet that uses to place on the patient surface to avoid the skin sparing effect or to compensate the irregular shape in hot spot area. There are various thicknesses of bolus but in this study, the 5mm and 10 mm thicknesses of bolus were used as shown in Figure 4.5.

Figure 4.5 The 5 mm (left) and 10 mm (right) thicknesses of bolus.

4.2 Methods

There are 3 main procedures of this study.

4.2.1 TLD preparation and calibration

4.2.1.1 TLD preparation

Cobalt-60 teletherapeutic machine (Theratron Elite 80 unit) was used to irradiate radiation dose for TLDs. Firstly, all of 200 rods TLD were irradiated and annealed 4 times for responsibility. The annealing was done by TLD heating with 400 °C for 1 hour and 100 °C for 2 hours in TLD annealing oven (PTW-TLDO). TLDs were calibrated at dose 200 cGy at the depth of maximum dose 0.5 cm ($D_{\max} = 0.5$ cm), field size 15x15 cm² and SAD technique 80 cm with bolus 0.5 cm covered.

4.2.1.2 TLD calibration

After annealing all of 200 TLDs for nullifying the residual background, 200 cGy of radiation dose was irradiated by Cobalt-60 machine. Then,

Irradiated TLDs were heated at 100 °C for 10 minutes to eliminate off-peak noise in TLD annealing oven (PTW-TLDO). After that, TLDs were read out by the TLD reader (HARSHAW TLD Model 5500 Automatic Reader) with heated at 260 °C in reading process and the charge of TLDs were showed in nanocoulomb (nC). The irradiation was done 2 times and the average of charge reading in each TLD was found. Then, TLDs were selected and divided into each group follow their uniformity ($\pm 10\%$) to giving dose of 200 cGy.

4.2.1.3 Linearity test of TLD

TLDs were irradiated with the dose 50, 100 and 300 cGy. The reading of charge was averaged and converted to absolute dose and plotted on a linear scale as a function of irradiated dose.

4.2.2 Treatment Planning

Firstly, TLDs were put in rod holders and put into totally 13 holds in breast Rando phantom follow these points

- Four points in the right upper breast Rando phantom slab. There was a superior point (B1), a medial point (B2), an inferior point (B3) and a lateral point (B4).
- Four points in the right lower breast Rando phantom slab. There was a superior point (B5), a medial point (B6), an inferior point (B7) and a lateral point (B8).
- Two points in Lung Rando phantom slab that close to the breast phantom. There was a lateral point (L1) and a medial point (L2).

And the other three points of TLDs with holder free were placed on breast Rando phantom surface under bolus covered (5 and 10 mm). There was a lateral point (S1), a center point (S2) and a medial point (S3). The TLDs' points are shown in Figure 4.6.

Figure 4.6 The points of TLD in breast Rando phantom slab (left) and the points of TLD in lung and on the surface with bolus covered (right).

After that, CT scan was used to scan the breast Rando phantom with 5 and 10 mm thicknesses bolus covered and obtained the slice images of the breast Rando phantom. Images were sent to treatment planning system both Eclipse and Pinnacle. The planning was done by SAD technique with Varian ClinacⁱX 6 MV photon beams and prescribed 200 cGy per fraction to 100% of point dose at point B6. Opposing tangential field technique with no wedge was planned with 69° in medial gantry angle and 240° in lateral gantry angle. Field sizes were 5 and 7.9 cm for X1 and X2 asymmetric jaw respectively and 16 cm symmetric Y in a medial field and 7.9 and 5 cm for X1 and X2 asymmetric jaw respectively and 16 cm symmetric Y jaw in a lateral field shown in Table 4.1. Both Eclipse and Pinnacle were planned by the same technique and calculated with dose contribution method at a prescription point. The doses in planning were calculated by the tool in the treatment planning system 3 times per each point and the comparisons of average dose in 13 points between Eclipse (AAA) and Pinnacles (CCC) were analyzed.

Table 4.1 A parameter of technique planning in both thicknesses of bolus and both algorithms.

Beam set up

Lat	7.9	5.0	8.0	8.0	240	107	105	106	106

4.2.3 Irradiation and measurement

TLDs were put into the points and placed on the surface points followed the figure 4.6. Varian ClinaciX was used to irradiate the breast Rando phantom that put TLDs inside as shown in Figure 4.7. The irradiation was done by opposing tangential fields technique followed the beam set up planning in both AAA and CCC algorithms seen in table 4.1. The irradiation was done 3 times for each algorithm. Finally, TLDs were read by Harshaw TLD reader and converted to average doses for each point. The comparisons of all 13 points between both algorithms planning and TLD measurements were found.

Figure 4.7 The Varian ClinaciX in irradiation process.

CHAPTER V

RESULTS AND DISCUSSION

5.1 TLD preparation and calibration

TLDs were selected (170 out of 200 rods) and separated into 3 groups followed their uniformity ($\pm 10\%$) to give the dose of 200 cGy. The linearity test was found by a linear relation of R^2 in all groups which shows in figure 5.1, 5.2 and 5.3.

Table 5.1 Irradiated doses and the average of absolute doses from TLD group 1 reading.

Irradiated Doses (cGy)	Average Doses \pm SD (cGy)	%Diff
50	46.20 \pm 1.16	-7.6 %
100	90.28 \pm 2.60	-9.72 %
200	200	0 %
300	281.25 \pm 8.35	-6.25 %

5.2 Radiation doses in treatment planning

The results in Table 5.4 show the doses on breast Rando phantom surface with bolus covered (point S1, S2, and S3) that were closely matched in both algorithms and both thicknesses of the bolus. The differences were between -0.21 to 1.33% in 5 mm thicknesses of bolus and 0 to 0.10% in 10 mm thicknesses of bolus. The doses in breast Rando phantom (Point B1 to B8) were also well matched in both algorithms and both thicknesses of the bolus in which the differences were -0.2 to 1.16% in 5 mm thicknesses of bolus and -0.15 to 0.90% in 10 mm thicknesses of bolus. The lung doses in point L1 were somewhat similar with 0.95% and 0.42% differences at 5mm and 10 mm bolus thicknesses. Nevertheless, overestimate doses in a lung (point L2) were found in AAA with 2.42% and 6.06% differences at 5 mm and 10 mm bolus thicknesses, respectively when compared with CCC algorithm. The graphs in Figure 5.4 shown that the percentage difference at L2 in 10 mm bolus thicknesses was clearly higher than 5 mm bolus thicknesses. In the prescription point (B6) of 200 cGy has shown the difference in 5 mm thicknesses of bolus was -0.20% and -0.01% in 10 mm thicknesses of bolus.

The planning doses in both algorithms and both bolus thicknesses were not difference at point S1 to L1, however point L2 was not. The planning dose by CCC algorithm was less at both thicknesses of bolus when compared with AAA algorithm

at point L2 which is heterogeneous lung region. As a result of high percentage differences at point L2 may cause from the point of low doses.

Table 5.4 A comparison of point doses in treatment planning by AAA algorithm (Eclipse) versus CCC algorithm (Pinnacle) in breast Rando phantom with 5 and 10 mm bolus covered.

5.3 Irradiated doses measurement

The irradiated TLDs were read in charge particle and converted to average doses shown in Table 5.5 and 5.6. The planning doses on breast Rando phantom surface with bolus covered (point S1, S2 and S3) were overestimated in both algorithms when compared with irradiated doses in which the differences were ranged between 6.1% to 12.3% and 3.1% to 8.3% at 5 and 10 mm bolus thicknesses, respectively. Same as the results of Chung et al [6] that showed the overestimated in surface and build-up doses in both treatment planning systems. The percentage differences in build-up region (point S1 to S3) were less than 15% that showed the good agreement with the study of Fraass et al [7] which recommended that the commissioning tolerance dose must not over 15% in complexity heterogeneous media in build-up region.

The planning doses in breast Rando phantom (Point B1 to B8) were overestimated in both algorithms when compared with irradiated doses which the differences were ranged between 10.3% to 18.1% and 4.4% to 12.9% at 5 and 10 mm bolus thicknesses, respectively.

The planning doses in lung (Point L1) were also overestimated in both algorithms when compared with irradiated dose which the differences were 14.1% and 15.3% at 5 mm bolus thicknesses, the differences were 8.3% and 6.6% at 10 mm bolus thicknesses. However, the planning doses in lung (point L2) were underestimated in both algorithms at 10 mm bolus thicknesses when compared with irradiated dose seen in Figure 5.6. Although the planning doses in lung (point L2) in CCC algorithm were underestimated at 5 mm bolus thicknesses, they were overestimated in AAA algorithm shown in Figure 5.5.

The percentage differences in breast Rando phantom and lung (point L1) were up to 18.1%. The high differences between planning doses and irradiated doses cause from the TLD calibration errors that large up to 9.72% differences as shown in Table 5.2. The other reasons cause from the irradiation process that different TLDs were used at the same point in irradiation repetition and also from the air gap between bolus and breast Rando phantom.

Table 5.5 A comparison of point doses from treatment planning doses versus TLD measurements in breast Rando phantom with 5 mm bolus thicknesses covered in both algorithms.

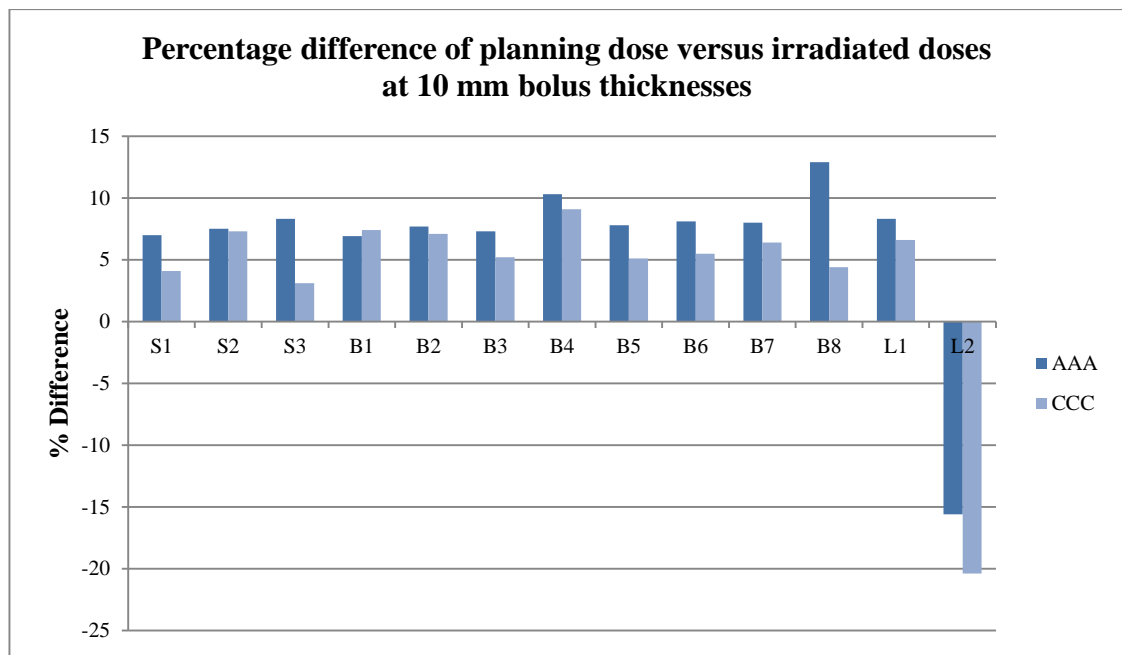

Figure 5.6 The graph of percentage difference between planning doses versus irradiated doses in both algorithms at 10 mm bolus thicknesses.

It seems that the percentage differences of planning doses versus irradiated doses at lung (point L2) were different compared with the other points. It might be due to point L2 was located at the point of beam edges region (seen in Figure 5.7) which leads to large uncertainty as fully illustrated with large standard deviation at both bolus thicknesses shown in Table 5.2 and 5.3.

Figure 5.7 The lung point L2 which located through the beam edges.

Above all, the CCC algorithm performed better in TLD measurements as shown in Table 5.2 and 5.3 which the average percentage differences between planning doses and irradiation doses were less than the AAA algorithm.

CHAPTER VI

CONCLUSIONS

In this study, both algorithms were not difference in treatment planning calculation of build-up region, breast Rando phantom and lung (point L1) in which the differences doses were less than 2%. The planning doses in build-up region, breast Rando phantom and lung (point L1) were overestimated in both thicknesses of the bolus and both algorithm when compared with irradiated dose except in lung (point L2) that was a point of beam edges region. However, the TLD measurements show that CCC algorithm performed overall better when compared with AAA algorithm at both thicknesses of the bolus.

The limitation of this study might cause the uncertainties in measurement. The process of placing bolus over the curve of breast Rando phantom might be the main cause of dose measurement errors from the air gap between bolus and surface of the phantom. In this study, 3 times repetition for measurements were done and TLDs were changed with bolus covered every time. This process might be the main limitation of this study and made the measurement errors. Another limitation is the grid hold pattern and small hold size in Rando phantom. The small size and many holds using in this study were difficult to find the fitted detector to put into all of the holds rather than TLD.

Further study might be required in other detectors or other techniques to have more evidence to illustrate the accuracy of dose calculation in build-up region and in lung tissue from the algorithms. The radiochromic film can be used by placing between the slabs of breast Rando phantom to measure the doses in any depths of breast phantom due to its small size and high resolution. The study of Alashrah et al [4] shown that radiochromic film (Gafchromic MD-55 film) and TLD-100 have a good agreement in surface dose and dose in the region after d_{\max} measurement when compared with Monte Carlo results.

APPENDIX

1. TLD Calibration

After annealing all of 200 TLDs with 400 °C for 1 hour and 100 °C for 2 hours, 200 cGy of radiation dose was irradiated by Cobalt-60 machine. Irradiated TLDs were heated at 100 °C for 10 minutes to eliminate off-peak noise. Then, TLDs were heated at 260 °C in reading process and the charge of TLDs reading was showed in nanocoulomb (nC). The Element Correction Coefficient (ECC_i) of individual TLD (seen in table 1.1, 1.2 and 1.3) was calculated by this equation below (where \bar{Q} is the average charge of all TLD and Q_i is the individual charge).

$$ECC_i = \frac{\bar{Q}}{Q_i}$$

After that, the TLDs that showed uniformity ($\pm 10\%$) to giving dose of 200 cGy were selected and separated into 3 groups. Each group was selected the standard TLDs that ECC_i value close to 1 (1% of all TLDs in each group). (* seen in the table means the standard TLD selected.)

Table A.3 The ECC_i value of each TLD in group 3. (cont.)

No.	TLD no.	Charge reading (nC)			ECC_i	%Diff
		1st	2nd	Q_i		
65	6	3510.041	3432.9	3471.4705	1.1199351	10.709113

The standard TLDs were annealed and irradiated with 200 cGy (repeated the upper step) and the individual reading was calculated as Q_{ci} (the correct charge integral) according to the equation below

$$Q_{ci} = Q_i \times ECC_i$$

The average of Q_{ci} (\bar{Q}_c) for standard TLDs was used for determination of the reader calibration factor (RCF) by the equation below, where D is the giving dose of 200 cGy.

$$RCF = \frac{\bar{Q}_c}{D}$$

The rest of TLDs except standard TLDs were annealed and irradiated with 200 cGy radiation dose to determine the individual element correction coefficient (ECC_{ci}) seen in table 1.4, 1.5 and 1.6 (where Q_i is the charge of individual TLD and D is the dose of 200 cGy).

$$ECC_{ci} = \frac{RCF \times D}{Q_i}$$

ECC_{ci} for each TLD, RCF for standard TLDs and the charge of individual TLD (Q_i) used for calculation the unknown dose (D_u) according to the equation below

$$D_u = \frac{Q_i \times ECC_{ci}}{RCF}$$

Table A.4 The ECC_{ci} value of each TLD in group 1.

BIOGRAPHY

NAME	Mr. Pongapisit Masunun
DATH OF BIRTH	08 January 1989
PLACE OF BIRTH	Chiang Mai, Thailand
INSTITUTIONS ATTENDED	Chiang Mai University, 2007: Bachelor of Science (Radiologic Technology) Mahidol University, 2011: Master of Science (Medical Physics)
RESEARCH GRANTS	Graduate Studies of Mahidol University Alumni Association
HOME ADDRESS	998/248 B-Republic condo Sukhumvit 101/1, Bangjak, Prakanong, Bangkok, Thailand, 10260 Tel. 089-9518400 Email: newzoozwen@gmail.com
PUBLICATION / PRESENTATION	13 th South-East Asian Congress of Medical Physics (SEACOMP 2015) Yogyakarta, Indonesia
