## ACKNOWLEDGEMENTS

I would like to express my sincere gratitude and deep appreciation to my major advisor, Assoc. Prof. Vipa Boonkitticharoen for her valuable advice, guidance, supervision, encouragement and assistance throughout this thesis. In addition, I am equally grateful to Asst. Prof. Chomporn Sitathanee and Assoc. Prof. Mantana Dhanachai my co-advisor for their important suggestions and comments in this experiment.

I would also like to express my appreciation to Mrs. Pornpan Yongvithisatid, Miss. Patchareporn Dechsupa and Miss Kumutinee Pairat for their training of the use the computerized treatment planning system (MultiPlan<sup>®</sup>) and advices about performance of CyberKnife. I also express my appreciation to Miss Pimolpun Changkaew and Miss Siwaporn Sakulsingharoj for their training of the use the computerized treatment planning system (Eclipse 8.9.15) and the helpful advice on thermoluminescence dosimeter. Specially thanks is express to Miss Supaporn Srisuwan and Mr. Thawesak Ukamphan for their assistance with the collection of my data.

I am particularly grateful for kindness in examining the research and providing suggestions for improvement given by Assoc. Prof. Kanjana Shotelersuk.

I wish to thank all teachers, lecturers, staffs and my classmates in the School of Medical Physics, Mahidol University for their kind support and teaching me in the Medical Physics Program.

Finally, I have to sincerely regard mention to my parents. Thank you for their understanding and inspiration throughout my whole study. The usefulness of this thesis, I dedicate to my family and all teachers who have taught me since my childhood.

COMPARATIVE ASSESSMENT OF SECOND CANCER RISKS AFTER  
PROSTATE CANCER TREATMENT BY STEREOTACTIC BODY  
RADIOTHERAPY AND THREE-DIMENSIONAL CONFORMAL  
RADIOTHERAPY

ABSTRACT

The purpose of this study assessed the second cancer risks in in-field (planning target volume, PTV) and organs at beam border (bladder and rectum) in patients with prostate cancer treated by CyberKnife stereotactic body radiotherapy (CK-SBRT) compared to three-dimensional conformal radiotherapy (3D-CRT). The risk of second cancer was determined based on the organ equivalent dose (OED) formulated by Schneider et al. The OED estimate was the summation of OED from primary beam, scatter/leakage and imaging dose. Treatment plans for six patients were optimized using MultiPlan<sup>®</sup> treatment planning system (TPS) of CK-SBRT and Eclipse TPS (Version 8.9.15) of 3D-CRT. Six MV photons were delivered according to CK-SBRT plan in 5 fractions of 7.25 Gy and 10 MV photons for 3D-CRT plan in 38 fractions of 2 Gy. OED for primary beam was calculated from the differential dose volume histogram (dDVH) while scatter/leakage radiation and imaging dose for each treatment plan were measured in Rando phantom by thermoluminescence dosimeter.

For PTV, the total OED generated by CK-SBRT was 1.4 times less than that of 3D-CRT ( $p << 0.0001$ ). In contrast, bladder OED by CK-SBRT was significantly greater than that of 3D-CRT ( $p = 0.0005$ ). For rectum, greater scatter/leakage OED ( $p = 0.036$ ) observed for CK-SBRT was compensated by lower image OED ( $p = 0.0004$ ) to render nearly equal total OED for both techniques. Overall, the primary OED contributed  $> 95\%$  to total OED, followed by image OED (between 1 - 4% contributions) and scatter/leakage OED ( $< 1\%$  contribution). The magnitude of total OED is mainly governed by primary beam targeting. CK-SBRT generates greater scatter/leakage OED than 3D-CRT but the risk is extremely small.

#### บทคัดย่อ

วัตถุประสงค์ของงานวิจัยนี้คือการประเมินความเสี่ยงต่อการเกิดมะเร็งทุติยภูมิในปริมาณของรังสี  
บำบัดและอวัยวะที่ติดกับขอบลำรังสี (กระเพาะปัสสาวะและลำไส้ตรง) ในผู้ป่วยมะเร็งต่อมลูกหมากจากการ  
บำบัดด้วยรังสีรักษาพร้อมฟิสิกส์แบบทั่วร่างกายด้วยเครื่อง CyberKnife (CK-SBRT) เปรียบเทียบกับรังสีรักษาสามมิติ  
(3D-CRT) ความเสี่ยงต่อมะเร็งทุติยภูมิวัดจาก organ equivalent dose (OED) ที่เสนอโดย Schneider และคณะ ซึ่ง  
การประเมินด้วย OED ได้จากผลรวมของ OED จากรังสีปฐมภูมิ รังสีกระเจิง/รังสีรั่วไหลและรังสีการถ่ายภาพ จาก  
การวางแผนการรักษาที่เหมาะสมในผู้ป่วยมะเร็งต่อมลูกหมากจำนวน 6 ราย ด้วยเครื่องคอมพิวเตอร์วางแผนการ  
รักษา MultiPlan<sup>®</sup> สำหรับ CK-SBRT และเครื่องวางแผนการรักษา Eclipse 8.9.15 สำหรับ 3D-CRT ที่พลังงาน 6  
MV จำนวน 5 ครั้ง ครั้งละ 7.25 Gy สำหรับการบำบัดด้วยวิธี CK-SBRT และจำนวน 38 ครั้ง ครั้งละ 2 Gy ตาม  
แผนการบำบัดด้วยวิธี 3D-CRT โดย OED ของรังสีปฐมภูมิคำนวณจาก differential dose volume histogram  
(dDVH) ในขณะที่ OED ของรังสีกระเจิง/รังสีรั่วไหลและรังสีการถ่ายภาพในแต่ละแผนการรักษาได้จากการวัด  
ภายใน Rando phantom โดยใช้ thermoluminescence dosimeter

OED ในปริมาณของรังสีบำบัดด้วยวิธี CK-SBRT มีค่าน้อยกว่า 3D-CRT ประมาณ 1.4 เท่า ( $p <<$   
0.0001) ในทางตรงข้ามค่า OED ในกระเพาะปัสสาวะจากการบำบัดด้วยวิธี CK-SBRT มีค่าสูงกว่าค่า OED จาก  
การบำบัดด้วย 3D-CRT ( $p = 0.0005$ ) สำหรับลำไส้ตรง OED ของรังสีกระเจิง/รังสีรั่วไหลจากการบำบัดด้วย CK-  
SBRT มีค่าสูงกว่าเมื่อเทียบกับ 3D-CRT ( $p = 0.036$ ) แต่ถูกหักล้างด้วย OED ของรังสีการถ่ายภาพที่น้อยกว่า 3D-  
CRT ( $p = 0.0004$ ) จึงทำให้ OED รวมจากวิธี CK-SBRT มีค่าใกล้เคียงกับ OED รวมจากวิธี 3D-CRT โดยมากกว่า  
95% ของ OED รวมจากวิธี CK-SBRT และ 3D-CRT เป็นผลมาจาก OED ของรังสีปฐมภูมิ ตามด้วย OED ของรังสี  
การถ่ายภาพ (ประมาณ 1 - 4%) และ OED ของรังสีกระเจิง/รังสีรั่วไหล (น้อยกว่า 1%) ดังนั้นปริมาณของ OED  
รวมส่วนใหญ่จะเป็นผลมาจากรังสีปฐมภูมิ สำหรับการบำบัดด้วยวิธี CK-SBRT แม้ว่าจะมีค่า OED ของรังสี  
กระเจิง/รังสีรั่วไหลสูงกว่าวิธี 3D-CRT แต่ความเสี่ยงที่เป็นผลจากรังสีกระเจิง/รังสีรั่วไหลมีค่าน้อยมาก

WB	Whole body weight
$\alpha$	A model parameter describing cell killing
$\beta$	A model parameter describing cell repopulation

## **CHAPTER I**

### **INTRODUCTION**

Prostate cancer (PCa) is the second most common cancer and the sixth leading cause of cancer death among men worldwide [1]. PCa incidence rates vary markedly from <10 (per 100,000) in the Republic of Korea, Thailand and India to >100 in the United States and New Zealand [1]. But mortality rates tended to be higher in less developed nations. Type of PCa treatment and underlying risks including old age, ethnicity, and family history of the disease are factors affecting rates of PCa mortality and trends [1, 2]. The treatment for PCa usually includes surgery and radiotherapy. However, surgery may not be appropriate in all patients, particularly for older patients and those in whom the likelihood of organ-confined disease is lower. Radiotherapy is the treatment choice for such patients and is often used to treat all stages of PCa. In addition, radiotherapy is a non-invasive technique which may reduce the risk of complications after surgery [3].

The increasing trend toward the detection of PCa at a younger age and earlier stage [4] and the availability of successful treatment options serve the main driving forces in increasing long-term survivorship. In the last decade, radiotherapy (RT) proved to have an equal efficiency compared to surgery in treatment of PCa. Various techniques of RT including brachytherapy, proton beam therapy and conformal radiotherapy (CRT) are used in management of clinically localized PCa [5]. Increase in patient survival following RT has been accounted by a number of strategies including dose escalation, target volume definition and organ movement tracking [6]. Long-term patient survival raises the issue of radiation-induced secondary malignancies (RISM).

It has been well established that RISM is a late phenomenon with a long latent period which might be inversely related to radiation dose. A study on pelvic irradiation reported by Quilty and Kerr [7] revealed that mean latent periods of bladder cancer after low dose and high dose irradiation are 30 and 16.5 years, respectively.

However, RISM is generally defined as cancers which arise after a latency period around 10 years inside or close to the treatment volume [8]. Sometimes, a latency of at least 5 years is also acceptable [9]. Risks of RISM after prostate irradiation were reported by several single institution/registry and multiregistry (SEER, Surveillance, Epidemiology and End Results) epidemiological studies involving RT in the two-dimensional (2D) era [10]. Data of single institution/registry studies are more informative than the multiregistry series for the knowledge of doses and type of treatment technique but are less conclusive for the time being because of small number of patients and relatively short follow-up. Multiregistry studies although included large number of patients (range: 85,815-144,761) had certain deficiencies including limited data of risk factors, insufficient details of therapy. Despite these limitations, findings from multiregistry studies suggest a modest increase in RISM after prostate radiation as approximately one in 70 patients undergoing prostate radiation and surviving more than 10 years will develop secondary cancer. The most common sites of RISM are organs adjacent to the radiation field, i.e. bladder and rectum [10]. In-field sarcoma [11, 12] and lung cancer at distant site are also reported [12, 13]. The increase risk of RISM is observed for patients treated by conventional 2D-RT, not after brachytherapy [10]. Modern radiotherapeutic techniques such as intensity-modulated radiotherapy (IMRT), stereotactic body radiotherapy (SBRT) may be associated with a higher risk of secondary cancers for generating greater scatter/leakage radiation than conventional RT [14] and subjecting to concomitant dose exposure from image-guided localization and verification procedures [15].

Assessment of RISM can also be conducted by dosimetric study [15]. Since RT increases the risk of RISM in a dose-dependent manner and most secondary cancers developed within or at the edge of the radiation field [16]. On this basis, planning studies may provide theoretical RISM risk estimates for modern RT until there is sufficient clinical evidence for the risks of RISM from these new treatment techniques [17-20]. Radiation to normal tissues consists of primary radiation from the treatment beam and secondary radiations from patient scatter, collimator scatter and machine leakage to the out-of-field tissues [15, 17]. A linear dose-response relationship is assumed for risks of RISM in the low dose out-of-field regions [17]. In higher dose, the dose-response relationships are nonlinear [17] and may related to

underlying biological processes including cell transformation, cell killing and cell repopulation [21, 22]. The linear-exponential model (LE) is formulated for the bell-shaped response curve and the linear-plateau model (LP) for curve with high-dose plateau response [17]. Schneider et al [23-25] proposed a concept of organ equivalent dose (OED), a dosimetric index of RISM, which includes dose volume histogram data from the primary beam component and scatter/leakage data for out-of-field component. The concept employs the LE [23] or LP model [24] to define the OED for a specified treatment plan.

Recently, there has been an interest in the use of highly conformal stereotactic body radiotherapy (SBRT) in the treatment of prostate cancer [26]. CyberKnife SBRT (CK-SBRT) in particular offers the physical advantage in precise dose-targeting (highly conformal tumor dose) and accurate dose delivery (with system for tracking organ motion) and the radiobiological advantage of large dose fraction in effective killing of late responding PCa ( $\alpha/\beta = 2.7$  Gy) [27]. Regarding to the impact of CK-SBRT on RISM risk, CK-SBRT in relative to 3D-CRT generates a larger volume of normal tissues exposed to low doses usually defined at 10% isodose [17] and may contribute to increased RISM risk. In addition, the increased monitor units required for treatment delivery will induce more scatter/leakage doses to out-of-field tissues. Tissues at the immediate vicinity of the irradiated volume may receive doses at intermediate (50% isodose) to high dose levels ( $\geq 95\%$  isodose) [17]. Pattern of dose distribution to these nearby normal tissues is dependent of the treatment technique. Reduced patient scatter to nearby tissue was estimated for IMRT compared to 3D-CRT [28]. In terms of high doses within the planning target volume (PTV), the risk of in-field sarcoma for CK-SBRT might be lower than 3D-CRT for the difference in size of dose per fraction.

In this study, overall risks of RISM to PTV, organs immediate to the treatment volume, i.e. bladder and rectum in patients with PCa treated by CK-SBRT were compared to risks from 3D-CRT. The OED concept was employed to assess RISM risk from treatment and concomitant imaging doses from tumor tracking in CK-SBRT and from field and setup verifications in 3D-CRT.

## CHAPTER II

### OBJECTIVES

#### **The main objectives:**

1. To determine the total organ equivalent dose (OEDs) including  $OED_{PTV}$ ,  $OED_{bladder}$  and  $OED_{rectum}$  of prostate cancer treatment plans for CK-SBRT and 3D-CRT.
2. To evaluate the differences between OEDs (including  $OED_{PTV}$ ,  $OED_{bladder}$  and  $OED_{rectum}$ ) obtained from CK-SBRT plan and 3D-CRT plan.

#### **The sub-objectives:**

1. To determine the differential dose volume histograms (dDVHs) for CK-SBRT and 3D-CRT treatment plans.
2. To determine OEDs (including  $OED_{PTV}$ ,  $OED_{bladder}$  and  $OED_{rectum}$ ) for the primary beam component of CK-SBRT and 3D-CRT treatment plans.
3. To determine OEDs (including  $OED_{PTV}$ ,  $OED_{bladder}$  and  $OED_{rectum}$ ) of the scatter/leakage component generated by CK-SBRT and 3D-CRT plans.
4. To determine OEDs (including  $OED_{PTV}$ ,  $OED_{bladder}$  and  $OED_{rectum}$ ) of the imaging doses for CK-SBRT and 3D-CRT treatments.
5. To determine the total OEDs (including  $OED_{PTV}$ ,  $OED_{bladder}$  and  $OED_{rectum}$ ) for CK-SBRT and 3D-CRT plans.

## **CHAPTER III**

### **LITERATURE REVIEWS**

#### **3.1 Second cancer risks after radiotherapy**

The study of Pickles et al [11] involved 39,261 men with prostate cancer from the British Columbia Tumor Registry. In the cohort, 9,890 of whom received high-dose radiation therapy to the prostate gland ( $\geq 45$  Gy) and 29,371 men who not treated with radiation. Their result showed an increase of 121% for sarcomas and 22% for colo-rectal cancers among patients with prostate cancer who received radiation therapy compared to those without. In addition, the reduce risk of second cancer was observed for bladder cancer among patients who received radiation therapy.

Brenner et al [12] used the data from the Surveillance, Epidemiology, and End Results Programs (SEER) to compare the risk of second cancers in 51,584 men with prostate cancer who received radiotherapy (3,549 of whom developed second cancers) with 70,539 men who received surgery without radiation therapy (5,055 of whom developed second cancers). Their result showed the risk of second cancers was significantly higher after radiotherapy compared to surgery. Particularly for long term survivors, the increase risk with radiotherapy was 15% for patients surviving  $\geq 5$  years and was 34% for patients surviving  $\geq 10$  years. The most significant contributors to increase risk in the irradiate group were cancer in organs closed to heavily irradiation sites such as bladder, rectum and in-field sarcomas. In addition, radiotherapy was also an increased risk of lung cancer at distant site. No significant difference between two treatment groups for the risk of out-of-field sarcomas.

In the study of Moon et al [13] involving 140,767 men with prostate cancer who survived  $\geq 5$  years after the date of their diagnosis to observe the incidence of second cancers after localized therapy for prostate cancer. Compared with men who were not treated by radiation therapy, men who received external beam radiation therapy (EBRT) as only form of radiation treatment had significantly increased risk of second cancers in several organs which were located within or close to treatment field

like bladder and rectum, as well as organs at sites in the upper body and other areas not potentially related to radiation therapy such as transverse colon, stomach, brain, and lung and bronchus. While men who received radiation therapy in the form of radioactive implants or isotopes either in isolation or in combination with EBRT did not have significantly different for second cancers occurring at these sites.

Diallo et al [16] reported the distribution of second cancer sites in relation to the irradiated volume among 115 patients from a cohort of 4,581 patients who developed a second cancer after childhood cancer radiotherapy. The location of second cancers were classified into three categories of regions, as follows: a. clearly-in-beam region, included second cancers located at more than 2.5 cm inward from the edge of irradiated volume, b. beam-bordering region, included second cancers located in the volume from 2.5 cm inside to 5 cm outside the irradiated volume, c. distant region, included second cancers outward at more than 5 cm from the irradiated volume. According to this classification, 12% of second cancers mostly sarcomas were observed in clearly-in-beam region with median doses 37.1 Gy (7.2 - 63.6), 66% consisted of sarcomas and carcinomas were observed in beam-bordering region with median doses 20.1 Gy (0 - 73.1), while 22% of second cancers mostly carcinomas were observed in distant region with median doses 0.3 Gy (0 - 3). In overall, the most second cancers was 78% observed in clearly-in-beam region and beam-bordering region. Only 22% of these patients were observed in distant region.

### **3.2 Dose-response relationship for second cancer incidence**

A dose-response relationship for radiation-induced cancer is demonstrated as a graph called a dose-response curve. There are two possibilities for the shape of the dose-response curves such as linear-exponential curve and plateau curve. The linear-exponential curve or bell-shaped curve was described by an initiation/inactivation model [21, 22], at low dose the incidence of cancer was a linear function of dose, and then begins to fall at higher dose due to cell killing effect [22] such as bone sarcoma [29] and thyroid cancer [30] as shown in Figure 3.1. While plateau curve, it has not decreased at the higher dose due to cell repopulation during and after radiation therapy which tend to counteract the effect of cell killing [22]. This can be described by

initiation/inactivation/proliferation model [21] such as cancer of breast, bladder and stomach [31] as shown in Figure 3.2.

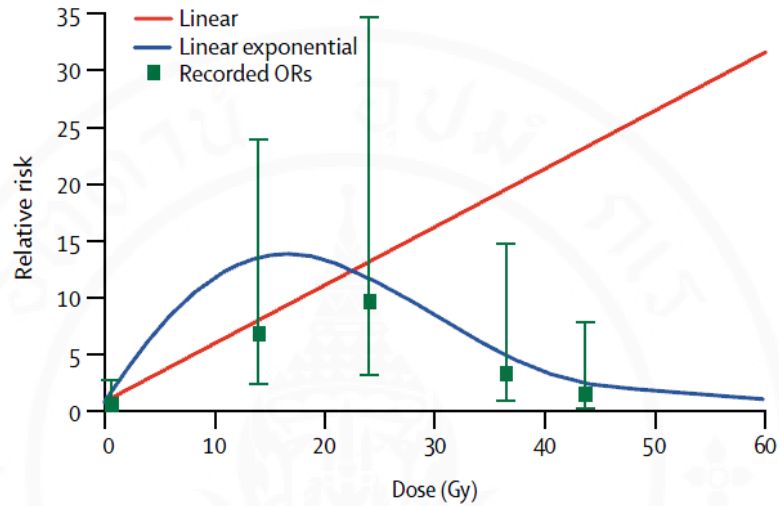

Figure 3.1 The dose-response curve for radiation induced thyroid cancer [30].

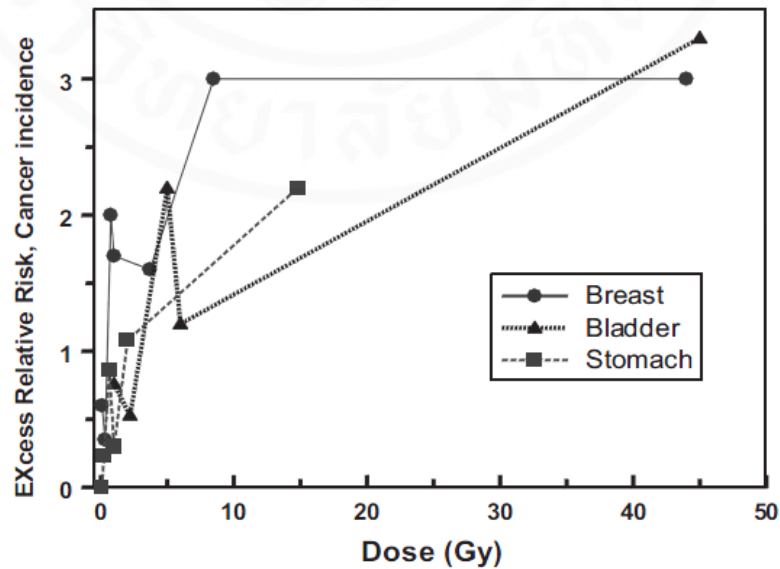

Figure 3.2 The dose-response curve for radiation induced cancer of breast, bladder and stomach after radiotherapy [31].

### 3.3 Risk estimation of second cancer after radiotherapy

Schneider et al [23-25] proposed a concept of organ equivalent dose (OED) in the estimation of second cancer risk. The basis for the OED model is the dose-response relationship for radiation-induced cancer. In low doses, the OED is simply the average organ dose, since for these doses the dose-response function behaves linearly with dose. However, at high doses is different due to cell killing or cell repopulation. Therefore, the two simulation models to determine the OED at high dose included linear-exponential model (equation 1), and plateau model (equation 2).

Linear-exponential model

$$\text{OED} = \frac{1}{V} \sum_i V_i D_i \exp(-\alpha D_i) \quad (1)$$

Plateau model

$$\text{OED} = \frac{1}{V} \sum_i V_i \frac{(1 - \exp(-\delta D_i))}{\delta} \quad (2)$$

Where  $\alpha$  is a linear-exponential model parameter ( $0.044 \text{ Gy}^{-1}$ ) [25] and  $\delta$  is a plateau model parameter ( $0.139 \text{ Gy}^{-1}$ ) [25], which were obtained from a combined fit the Japanese atomic bomb survivors and Hodgkin's patients cured by radiotherapy.

Schneider et al [32] used OED in the calculation of radiation-induced second cancers in patients with prostate cancer treated by IMRT and 3D-CRT with 15 MV and 18 MV photon beams. The impacts of primary dose distribution as well as scatter/leakage radiation were analyzed. The differential dose volume histograms (dDVHs) data of the calculated treatment plan were used to determine the OED for primary doses. For the OED of scatter/leakage radiation was obtained from measured data for a point located 50 cm away from the center of treatment field. When compared to the 3D-CRT using the linear-exponential model, an increased risk of second cancer among prostate cancer patients who treated by IMRT was 18.2% for 15 MV and 21.2% for 18 MV observed in OED for primary doses, while 50% for 15 MV

and 43.8% for 18 MV observed in the OED for scatter/leakage radiation. In overall, the total OEDs from IMRT was 1.2 times for 15 MV and 1.3 times for 18 MV higher than from 3D-CRT.

## **CHAPTER IV**

### **MATERIALS AND METHODS**

#### **4.1 Patients**

This study included six patients with prostate cancer who were treated at the Radiosurgery Center, Ramathibodi Hospital. Two treatments by CK-SBRT and 3D-CRT were planned for each of six patients. The CK-SBRT treatment was delivered by Accuray CyberKnife G4 System (Accuray Incorporated, Sunnyvale, CA) with a 6 MV linear accelerator (linac) mounted on a computer-controlled robotic arm. The 3D-CRT treatment was delivered by Varian Clinac iX (Varian Medical Systems, Palo Alto, CA) with seven irradiation fields using 10 MV photons. Details for treatment plans are presented in Tables 4.1 and 4.2. This study was approved by the ethic committee of the Faculty of Medicine Ramathibodi Hospital.

#### **4.2 Computerized treatment planning system**

The computerized treatment planning system used in CK-SBRT is the MultiPlan<sup>®</sup> Treatment Planning System (Accuray Incorporated, Sunnyvale, CA). The MultiPlan<sup>®</sup> system can create the treatment plan which has excellent conformality and coverage made possible by steep dose gradients. The system provides tools necessary to performing a complete range of treatment planning tasks, i.e. from image registration, target and critical structure delineation, through dose optimization, calculation and plan review. The system calculates dose on the basis of the ray tracing algorithm.

The 3D-CRT treatment planning system is the Eclipse version 8.9.15 (Varian Medical Systems, Palo Alto, CA). The Eclipse system uses the Analytical Anisotropic Algorithm (AAA) for dose calculation and also equipped with effective tools to reduce the complexity of contouring tasks, simplify field set up and facilitate a fast calculation which reduces treatment planning time.

### 4.3 Accuray CyberKnife G4 Systems

Accuray CyberKnife G4 System (Figure 4.1) is used for CK-SBRT treatment. This system uses a 6 MV linear accelerator mounted on a six-axis robotic manipulator and is integrated with an imaging system to localize the target during treatment. The imaging system consists of two ceiling-mounted kilovoltage (kV) X-ray sources and two image detectors mounted on the floor. The field size of radiation beam is determined by a circular collimator with diameters ranging from 5 mm to 60 mm in 12 steps.

Figure 4.1 Accuray CyberKnife G4 system.

### 4.4 Linear accelerator

The Varian Clinac iX linear accelerator (Figure 4.2) used for 3D-CRT treatment, generates dual photon beam energies of 6 and 10 MV and six electron beam energies of 4, 6, 9, 12, 16, 20 MeV. Field sizes of photon beam range from  $0.5 \times 0.5 \text{ cm}^2$  to  $40 \times 40 \text{ cm}^2$  at the isocenter and electron beam from  $6 \times 6 \text{ cm}^2$  to  $25 \times 25 \text{ cm}^2$ . The distance from the source of the treatment machine to the isocenter is 100 cm. There are six stationary therapy dose rates ranging from 100 to 600 monitor units per minute.

The imaging system uses the megavoltage treatment beam as imaging source and the electronic portal imaging device (EPID) mounted on the linear accelerator for image capture. This imaging system is capable of creating two-dimensional electronic images used for the patient setup verification and individual field placement verification.

Figure 4.2 Varian Clinac iX linear accelerator.

#### **4.5 The Alderson Rando Phantom**

The Alderson Rando phantom (Figure 4.3) was used to measure the scatter/leakage doses and imaging doses. The size of phantom is a 155 cm tall and weighed 50 kg. The phantom consists of tissue-equivalent materials which are transected horizontally into slabs of 2.5 cm thickness. Each slice contains a matrix of holes with 5 mm in diameter spacing 1 cm apart. These holes are filled with bone-equivalent, soft tissue-equivalent or lung tissue-equivalent pins in relevant locations and the pins can be replaced by TLD.

Figure 4.3 The Alderson Rando phantom.

## 4.6 Thermoluminescence dosimeter (TLD) system

### 4.6.1 Thermoluminescence dosimeter (TLD-700)

The TLD-700 (Harshaw Chemical Company) in the form of rod, with 1 mm diameter and 5 mm long (Figure 4.4), was used to measure the scatter/leakage radiations from CK-SBRT and 3D-CRT technique and the imaging doses from 3D-CRT technique. The dosimeter is lithium fluoride (LiF) crystals doped with magnesium and titanium (LiF:Mg,Ti). The TLD-700 consists of  $^6\text{Li}$  (0.01%) and  $^7\text{Li}$  (99.99%). The useful dose range of the TLD-700 is  $10\mu\text{Gy}$ - $10\text{Gy}$  [33].

Figure 4.4 Array of thermoluminescence dosimeter (TLD-700) in the TLD planchet.

#### 4.6.2 Thermoluminescence dosimeter (TLD-100H)

The TLD-100H (Harshaw Chemical Company) in the form of a square chip with a size of 3.2 mm x 3.2 mm x 0.38 mm and a density of 2.48 g/cm<sup>3</sup> (Figure 4.5), was used to measure the imaging doses from CK-SBRT technique. The dosimeter is lithium fluoride (LiF) crystals doped with magnesium, copper and phosphorus (LiF:Mg,Cu,P). The TLD-100H consists of <sup>6</sup>Li (7.36%) and <sup>7</sup>Li (92.14%). The useful dose range of the TLD-100H is 1 μGy-20 Gy [34].

Figure 4.5 Array of thermoluminescence dosimeter (TLD-100H) in the TLD planchet.

#### 4.6.3 Thermoluminescence reader

The automatic TLD reader is Harshaw model 5500 with TLD Shell software (Figure 4.6). The reader uses a hot nitrogen gas heating system and the heating temperature is controlled by the WinREMS software. The temperature controlled software run by a Window operating system is a closed loop feedback capable of producing linearity ramped temperature up to 400 °C with the accuracy of  $\pm 1$  °C. The TLD reader can be calibrated in gray or sieverts with different scales. It can be used for various types of TLD.

Figure 4.6 The automatic TLD reading system.

#### 4.6.4 TLD annealing oven

The TLD annealing oven (Figure 4.7) is equipped with two standard programs for annealing and preheating. Annealing program is used for annealing TLD before irradiation, while preheating program is used for preheating TLD before reading. The oven temperature is adjusted by the TLDO software.

Figure 4.7 The TLD annealing oven.

#### 4.7 Treatment planning

CT scan or MRI from each patient were recorded in DICOM standard format and imported to MultiPlan<sup>®</sup> treatment planning system of CK-SBRT and to Eclipse treatment planning system (version 8.9.15) of 3D-CRT. Dose distributions between PTV, bladder and rectum were calculated based on contours drawn by the oncologist. The PTV for CK-SBRT was defined as the GTV plus 5 mm in all directions except for the posterior margin which was set at 3 mm. For 3D-CRT, the margin of PTV was assigned at 7 mm from GTV in all directions except for posterior which was set at 5 mm. The optimized CK-SBRT plan was the plan capable of delivery a prescribed dose of 36.25 Gy to the PTV in 5 fractions of 7.25 Gy without violating the dose constraints of bladder (<15 ml and maximum point dose 38 Gy) and rectum (<20 ml and maximum point dose 38 Gy) as suggested by Timmerman [35]. For 3D-CRT, the plan with seven irradiation fields using 10 MV photons was optimized to deliver the prescribed dose of 76 Gy to the PTV in 38 fractions of 2 Gy without violating the dose constraints to bladder and rectum as suggested by Ramathibodi protocol. Parameters involving treatment delivery such as energy, beam

orientation, collimator size, treatment MUs, etc. were described in Tables 4.1 and 4.2.

**Table 4.1 The CK-SBRT treatment plans for six patients with prostate cancer.**

#### 4.8 Determination of the total organ equivalent dose (OED<sub>T</sub>)

The total organ equivalent dose (OED<sub>T</sub>) for PTV, bladder and rectum from CK-SBRT and 3D-CRT treatment plans were described by equation 3.

$$\text{OED}_T = \text{OED}_{\text{prim}} + \text{OED}_{\text{scatter/leakage}} + \text{OED}_{\text{image}} \quad (3)$$

Where  $\text{OED}_{\text{prim}}$  = organ equivalent dose for primary beam.

$\text{OED}_{\text{scatter/leakage}}$  = organ equivalent dose for scatter/leakage radiation.

$\text{OED}_{\text{image}}$  = organ equivalent dose for imaging doses.

#### 4.8.1 Determination of the OED primary for primary beam component

OED of the primary beam component is the equivalent dose defined for organs in volume of CT scan [32].

- a. OED primary for PTV ( $OED_{\text{prim, PTV}}$ )

$$OED_{\text{prim, PTV}} = \frac{1}{V_{\text{PTV}}} \sum_i dDVH D_i e^{-\alpha D_i} \quad (4)$$

Where  $V_{\text{PTV}}$  = total organ volume in  $\text{cm}^3$  for PTV.

$dDVH$  = differential dose volume histogram in corresponding to  $D_i$ ,  
 $dDVH$  was calculated at 1% dose gradient for CK-SBRT  
 and 0.2 Gy dose gradient for 3D-CRT.

$\alpha$  =  $0.044 \text{ Gy}^{-1}$  a model parameter describing cell killing [25].

- b. OED primary for bladder ( $OED_{\text{prim, blad}}$ )

$$OED_{\text{prim, blad}} = OED_{\text{in PTV}} + OED_{\text{out PTV}}$$

$$= \left[ \frac{1}{V_{\text{blad}}} \sum_i dDVH D_i e^{-\alpha D_i} \right]_{\text{in PTV}} + \left[ \frac{1}{V_{\text{blad}}} \sum_i dDVH \frac{(1-e^{-\delta D_i})}{\delta} \right]_{\text{out PTV}} \quad (5)$$

Where  $V_{\text{blad}}$  = total organ volume in  $\text{cm}^3$  for bladder.

$dDVH$  = differential dose volume histogram in corresponding to  $D_i$ ,  
 $dDVH$  was calculated at 1% dose gradient for CK-SBRT  
 and 0.2 Gy dose gradient for 3D-CRT.

$\alpha$  =  $0.044 \text{ Gy}^{-1}$  a model parameter describing cell killing [25].

$\delta$  =  $0.139 \text{ Gy}^{-1}$  a model parameter describing cell repopulation [25].

- c. OED primary for rectum ( $OED_{\text{prim, rec}}$ )

$$OED_{\text{prim, rec}} = OED_{\text{in PTV}} + OED_{\text{out PTV}}$$

$$= \left[ \frac{1}{V_{\text{rec}}} \sum_i d\text{DVH} D_i e^{-\alpha D_i} \right]_{\text{in PTV}} + \left[ \frac{1}{V_{\text{rec}}} \sum_i d\text{DVH} \frac{(1-e^{-\delta D_i})}{\delta} \right]_{\text{out PTV}} \quad (6)$$

Where  $V_{\text{rec}}$  = total organ volume in  $\text{cm}^3$  for rectum.

$d\text{DVH}$  = differential dose volume histogram in corresponding to  $D_i$ ,  
 $d\text{DVH}$  was calculated at 1% dose gradient for CK-SBRT  
and 0.2 Gy dose gradient for 3D-CRT.

$\alpha$  = 0.044  $\text{Gy}^{-1}$  a model parameter describing cell killing [25].

$\delta$  = 0.139  $\text{Gy}^{-1}$  a model parameter describing cell repopulation  
[25].

To account for the biological difference in different dose per fraction used for CK-SBRT and 3D-CRT treatment, all  $D_i$ 's from DVH data were normalized to an equivalent dose in 2 Gy per fractions ( $\text{EQD}_2$ ) which described by equation 7.

$$\text{EQD}_2 = D_i \left[ \frac{d_i + \alpha/\beta}{2 + \alpha/\beta} \right] \quad (7)$$

Where  $D_i$  = dose associated with the  $d\text{DVH}_i$ .

$d_i = D_i/\text{fraction number}$ , the fraction number was 5 and 38 for CK-SBRT and 3D-CRT, respectively.

$\alpha/\beta = 2.7$  Gy for prostate [27], 10 Gy for bladder and rectal complication [36, 37].

#### 4.8.2 Determination of the $\text{OED}_{\text{scatter/leakage}}$

a. The  $\text{OED}_{\text{scatter/leakage}}$  for CK-SBRT and 3D-CRT treatment plans was calculated by plateau model which described by equation 8.

$$\text{OED}_{\text{scatter/leakage}} = \frac{V_T (1-e^{-\delta \bar{D}_{\text{WB}}})}{V_{\text{WB}} \delta} \quad (8)$$

Where  $V_T$  was whole volume of PTV, bladder and rectum, and  $V_{\text{WB}}$  was the whole body volume receiving scatter/leakage dose ( $D_{\text{SL}}$ ) of D Gy which calculated

from the patient whole body weight (WB) in g , with a body density (G) of  $1.07 \text{ g/cm}^3$  for male [38] which defined by equation 9.

$$V_{WB} = \frac{WB}{G} (\text{cm}^3) \quad (9)$$

b. Scatter/leakage dose from treatment ( $D_{SL}$ ) was measured for each treatment plan. Firstly, TLD-700 rods were placed in ten positions within the Rando phantom. The ten measured positions were outside the treatment field (Figure 4.8). Points of measurement in the Rando phantom are shown in Table 4.3. The phantom was setup exactly the same position as the patient was treated. Scatter/leakage doses from CK-SBRT plans were measured by irradiating the phantom with a dose of 5 Gy from 6 MV photons and for 3D-CRT plans with a dose of 10 Gy from 10 MV photons. The measurements were repeated 3 times. The scatter/leakage dose was calculated by dividing individual TLD dose with the total MU used in phantom irradiation. The Gy/MU was a unit of the scatter/leakage dose which measured by TLD divided by the total MU which used for the calculation of whole body dose from scatter/leakage radiation. The scatter/leakage dose from the treatment ( $D_{SL}$ ) was Gy/MU for total body multiplied by the total MU used for treatment.

**Table 4.3 Points of measurement for scatter/leakage dose in Rando phantom.**

Organ	Slab number	Distance from tumor center (cm.)
Brain	2	70
Right and left thyroid	8	54
Right and left lung	14	38.8
Sternum	14	39.4
Liver	18	28.5
Stomach	18	25.5
Right and left kidney	21	20.7

Figure 4.8 Positions of TLD in Rando phantom for the scatter/leakage dose measurement.

#### 4.8.3 Determination of the $OED_{image}$

a. The  $OED_{image}$  for CK-SBRT and 3D-CRT treatment plans were calculated by plateau model which described by equation 10.

$$OED_{image} = \frac{(1 - e^{-\delta \bar{D}_{image}})}{\delta} \quad (10)$$

b. Using the Rando phantom, the imaging doses were measured with TLD-100H chips for CK-SBRT treatment plans and TLD-700 rods for 3D-CRT treatment plans. TLDs were placed at 15 positions in the Rando phantom (Figure 4.9). Points of measurement in the Rando phantom are shown in Table 4.4. The phantom was setup the same position as patients were treated. For CK-SBRT, the exposure technique for imaging the target location was 120 kV, 100 mA and 100 ms (10 mAs) for each image. A total of 150 exposures were given per each imaging dose measurement.

In 3D-CRT, each patient received doses from image verification protocol, for seven treatment fields and anterior-posterior plus lateral setup. Imaging for treatment field and setup verification was performed by the EPID system used a double exposure technique (MLC versus open field) with a low dose mode (1MU/image). Imaging doses were measured from cumulative doses of five repeated image verification protocols. The measurement was repeated 3 times.

**Table 4.4 Points of measurement for image dose in the Rando phantom.**

<b>Organ/location</b>	<b>Points of measurement</b>
Brain	1
Right and left thyroid	2, 3
Right and left lung	4, 5

Liver	7
Stomach	8
Right and left kidney	9, 10
Bladder	11
Rectum	12
Tumor center	13
Skin dose	14, 15

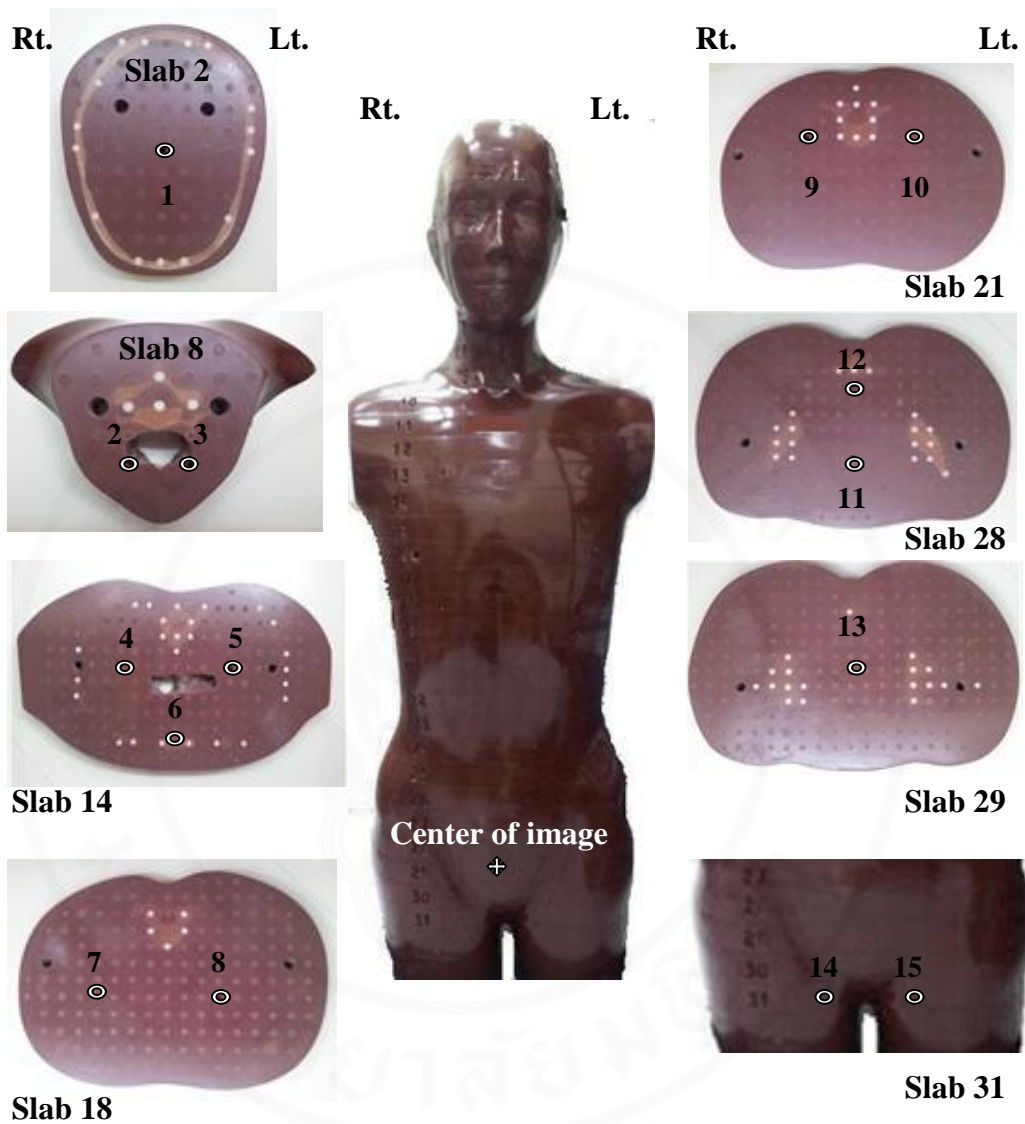

Figure 4.9 Positions of TLD in Rando phantom for the image dose measurement.

#### 4.9 Statistical analysis

Student t-test [39] was used to analyze the difference in OED from CK-SBRT and 3D-CRT treatment plans. All of the statistical tests were two-tailed, and  $p \leq 0.05$  was considered statistically significant.

## CHAPTER V

### RESULTS

#### 5.1 OED determination for primary beam component

##### 5.1.1 EQD<sub>2</sub> calculation

Physical doses from the differential dose volume histograms (dDVHs) of CK-SBRT and 3D-CRT treatment plans were converted to EQD<sub>2</sub> using equation 7. Organs at risks were PTV, bladder and rectum. EQD<sub>2</sub> for PTV treated by CK-SBRT and 3D-CRT are presented in Table 5.1. Parts of bladder and rectum included in PTV and outside PTV, EQD<sub>2</sub>'s were calculated using  $\alpha/\beta$  of 10 Gy [36, 37] (Tables 5.2 and 5.3).

**5.1.2 Calculation of OED primary (OED<sub>prim</sub>)**

OED<sub>prim</sub> in PTV was calculated using linear-exponential model and outside PTV using plateau model. OED<sub>prim</sub>'s for PTV, bladder and rectum were calculated using equations 4, 5, 6, respectively and are presented in Tables 5.4-5.6.

**Table 5.4 OED<sub>prim</sub> for PTV treated by CK-SBRT and 3D-CRT.**

Table 5.7 shows the OED<sub>prim</sub> for PTV, bladder and rectum from CK-SBRT compared with 3D-CRT. The paired t-test was used to test for the difference between the two treatment plans. OED<sub>prim, PTV</sub> from 3D-CRT was significantly higher than that from CK-SBRT whereas OED<sub>prim, blad</sub> was lower. No significant difference between two treatment plans could be observed for OED<sub>prim, rec</sub>.

**Table 5.7 Comparison between OED<sub>prim</sub>'s from CK-SBRT and 3D-CRT.**

Organ	CK-SBRT	3D-CRT	CK – SBRT	P-value

## 5.2 Scatter and leakage dose component

### 5.2.1 Scatter/leakage dose ( $D_{SL}$ )

Scatter/leakage dose ( $D_{SL}$ ) to total body was estimated from measured data in ten positions outside the treatment field (Table 5.8). Firstly, dose in each of the ten positions was divided by total MU used in phantom irradiation to obtain the scatter/leakage dose in Gy/MU. Then doses measured at ten positions in Rando phantom was averaged to obtain the scatter/leakage dose to the whole body [40]. Scatter/leakage doses ( $D_{SL}$ ) from treatment at ten positions are presented in Table 5.9. For each patient, the scatter/leakage dose from the treatment ( $D_{SL}$ ) was the whole body dose in Gy/MU multiplied by the total treatment monitor unit (MU) for each patient as shown in Table 5.10.

**Table 5.8 Scatter/leakage dose (Gy/MU) from TLD measurement in 10 positions outside the treatment field from CK-SBRT and 3D-CRT.**

Organ	Distance from tumor center, cm	Scatter/leakage dose, Gy/MU	
		CK-SBRT $\bar{X}(SD)$	3D-CRT $\bar{X}(SD)$

**Table 5.9 Scatter/leakage dose ( $D_{SL}$ ) to organ outside the treatment field at 10 positions from CK-SBRT and 3D-CRT.**

Organ	Distance from tumor center, cm	Scatter/leakage dose, Gy	
		CK-SBRT $\bar{X}(SD)$	3D-CRT $\bar{X}(SD)$
Brain	70	0.0896 (0.0004)	0.0230 (0.0010)
Right thyroid	54	0.1481 (0.0008)	0.0296 (0.0006)
Left thyroid	54	0.1263 (0.0020)	0.0264 (0.0004)
Right lung	38.8	0.0815 (0.0006)	0.0326 (0.0006)
Left lung	38.8	0.0922 (0.0011)	0.0307 (0.0015)
Sternum	39.4	0.1178 (0.0008)	0.0361 (0.0004)
Liver	28.5	0.1014 (0.0004)	0.0559 (0.0007)
Stomach	25.5	0.1008 (0.0017)	0.0520 (0.0002)
Right kidney	20.7	0.1216 (0.0009)	0.1545 (0.0007)
Left kidney	20.7	0.1485 (0.0007)	0.1740 (0.0009)
<b>Whole body</b>		0.1052 (0.0002)	0.0510 (0.0001)

Scatter/leakage dose from treatment ( $D_{SL}$ ) at ten positions ranged from 0.0815 to 0.1485 Gy, with an average dose to whole body of 0.1052 Gy ( $SD = 0.0002$ ) for CK-SBRT plan. For 3D-CRT plan, the scatter/leakage dose ranged from 0.0230 to 0.1740 Gy with an average dose to whole body of 0.0510 Gy ( $SD = 0.0001$ ). Scatter/leakage dose from CK-SBRT plan was 2.06 times higher than from 3D-CRT plan ( $p = 0.0086$ , by paired t-test).

## 5.3 Imaging dose component

### 5.3.1 Imaging dose

Imaging dose was estimated from measured data in Rando phantom. For CK-SBRT, the exposure technique was 120 kV, 10 mAs. Image doses from 150 exposures measured at 15 positions are shown in Table 5.15.

**Table 5.15 Image doses from 150 exposures in 15 positions for CK-SBRT technique with exposure technique set at 120 kV, 10 mAs. Data are means (SD).**

Organ	Image dose (Gy)		
	150 images	1 image	Total treatment
<i>Outside the image field</i>			
Brain	8.75E-05 (1.04E-05)	5.84E-07 (6.91E-08)	0.0006 (3.09E-05)
Right thyroid	3.14E-04 (3.38E-05)	2.09E-06 (2.25E-07)	0.0023 (0.0001)
Left thyroid	3.24E-04 (3.43E-05)	2.16E-06 (2.29E-07)	0.0023 (0.0001)

Stomach	0.0015 (0.0001)	9.96E-06 (7.65E-07)	0.0108 (0.0003)
Right kidney	0.0048 (0.0006)	3.23E-05 (4.21E-06)	0.035 (0.0019)
Left kidney	0.0062 (0.0011)	4.15E-05 (7.55E-06)	0.045 (0.0034)
Bladder	0.0369 (0.0034)	2.46E-04 (2.24E-05)	0.2666 (0.01)
Rectum	0.0091 (0.0012)	6.04E-05 (8.12E-06)	0.0655 (0.0036)
Tumor center	0.019 (0.0033)	1.26E-04 (2.20E-05)	0.1369 (0.0098)
*Skin dose	0.097 (0.0013)	6.46E-04 (8.87E-06)	0.7013 (0.004)

Imaging doses outside the image field for total treatment ranged from 0.0006 to 0.0033 Gy while inside the image field ranged from 0.0086 to 0.1369 Gy. Organ of interest such as PTV, bladder and rectum for each patient was different according to the number of images taken for the whole treatment which were calculated based on a single image dose as shown in Table 5.15. The results of calculate for each patient are shown in Table 5.16.

**Table 5.16 Imaging doses estimated for PTV, bladder and rectum in CK-SBRT treatment.**

For 3D-CRT technique, each patient received dose from image verification protocol for seven treatment fields and anterior-posterior plus lateral setup. The image doses from field and setup verification determined for a single protocol were expressed in Gy/MU. Results of measurements are presented in Table 5.17. The imaging dose from verification protocol was the doses in Gy/MU multiplied by MU for seven treatment fields and anterior-posterior plus lateral setup as shown in Table 5.18

**Table 5.17 Image doses from field and setup verification for 3D-CRT technique measured in 15 positions with 6 MV photon beam. Data are means (SD).**

In 3D-CRT, each patient received equal imaging doses from field and setup verification protocol. Image doses to PTV, bladder and rectum were 0.1465 Gy, 0.1184 Gy, 0.0991 Gy, respectively (Table 5.18).

**5.3.2 Calculation of OED image (OED<sub>image</sub>)**

The OED<sub>image</sub> was calculated using the equation 10. The imaging doses to PTV, bladder and rectum were converted to EQD<sub>2</sub>. OED<sub>image</sub> based on EQD<sub>2</sub> estimates were calculated and are shown in Table 5.19.

**Table 5.19 OED<sub>image</sub> for CK-SBRT and 3D-CRT.**

Organ	EQD <sub>2</sub>		OED, Gy		CK – SBRT *	P-value*
	CK-SBRT	3D-CRT	CK-SBRT	3D-CRT	3D – CRT

\*Comparison of OED between CK-SBRT and 3D-CRT

OED<sub>image</sub> for bladder from CK-SBRT technique was significantly greater from 3D-CRT technique whereas OED<sub>image</sub> of rectum was lower. No significant difference between two treatment plans for OED<sub>image</sub> of PTV.

#### 5.4 Total organ equivalent dose ( $OED_T$ )

Table 5.20-5.22 shows the total organ equivalent dose ( $OED_T$ ) for PTV, bladder and rectum from CK-SBRT compared with 3D-CRT plans.  $OED_T$  for these organs were the summation of the  $OED_{prim}$ ,  $OED_{scatter/leakage}$ , and  $OED_{image}$ .  $OED_{prim}$  (>95%) was a major part of  $OED_T$  followed by  $OED_{image}$ , while  $OED_{scatter/leakage}$  was a small contribution to the  $OED_T$ . For the PTV,  $OED_T$  from CK-SBRT was 29.06% less than that from 3D-CRT ( $p \ll 0.0001$ ). In contrast, CK-SBRT induced larger OED to the bladder, i.e. 17.57% ( $p = 0.0005$ ), whereas no significant difference in OEDs could be observed for the rectum by both techniques.

Figures 5.1-5.3 compare OEDs for primary beam, scatter/leakage and imaging dose generated by CK-SBRT and 3D-CRT to the PTV, bladder and rectum.

## CHAPTER VI

### DISCUSSION

The risk of secondary malignancies after radiotherapy is a subject of concern for modern conformal radiotherapy techniques. Precise dose targeting will allow dose escalation to achieve a better cure rate and long-term survivorship. The use of highly conformal SBRT in the treatment of prostate cancer (PCa) bases on the capability in accurate delivery (with the aid of an organ motion tracking system) of highly conformal tumor dose and the use of ablative dose fractions for effective killing of the late responding PCa ( $\alpha/\beta = 2.7$  Gy) [26, 27]. Theoretical prediction of radiation-induced secondary malignancies (RISM) after fractionated radiotherapy using the linear-quadratic formular suggests that hypofractionated radiotherapy has the potential for secondary cancer reduction. Of particular interest is the more pronounced reduction on risks of sarcoma than carcinoma risks [41].

Like many other modern radiotherapeutic techniques, CK-SBRT treatment in comparing to the conventional 3D-CRT involves larger number of small fields to achieve precise tumor targeting resulting larger volume of normal tissues being exposed to small radiation doses. By this token, better local tumor control and reduced normal tissue complications can be expected for CK-SBRT. Despite this therapeutic efficacy, there is a concern that CK-SBRT in relative to 3D-CRT might be associated with an increase in risk of RISM for many reasons, namely: the spreading of low doses and hence carcinogenic effect to large volume of normal tissues, larger monitor unit (MU) requirement contributing larger total body doses from collimator scatter and machine leakage radiations, concomitant imaging doses from tumor motion tracking [15, 17, 31].

In this study, the impact of CK-SBRT on RISM compared to 3D-CRT was evaluated for the planning target volume (PTV) and organs at beam borders including bladder and rectum. Since RISM is commonly observed inside or close to the treatment volume [8], RISM was assessed by employing the organ equivalent dose

(OED), a dosimetric index of RISM developed by Schneider et al [25]. OED projecting in-field risk was calculated by the linear-exponential model (LE) [23] and out-of-field risk by the linear-plateau model (LP) [24]. All physical doses were normalized to an equivalent dose in 2 Gy fractions (EQD<sub>2</sub>) by applying linear-quadratic model (LQ) model. The LQ model is suggested to be a reliable and mechanically plausible model for designing protocol in the dose per fraction range from 2 to 10 Gy [42]. A loss in accuracy can be expected above 10 Gy [42]. However, animal studies demonstrated the model validity for designing clinical trials with fraction doses of up to 15-18 Gy [42]. In evaluation of the primary beam effect on PTV where similar dose distributions were observed for CK-SBRT and 3D-CRT plans, OED<sub>prim</sub> from CK-SBRT was 1.43 times less than OED<sub>prim</sub> from 3D-CRT ( $p \ll 0.0001$ ). The difference might be due to difference in size of dose per fraction, i.e. ablative dose fractions used in CK-SBRT treatment against the conventional dose fractions in 3D-CRT. The effectiveness of large dose fraction in better cell killing than conventional dose fraction may help elimination of radiation-induced mutant cells hence reducing the risk of RISM [14].

For non-target organs within the planning CT volume, OED<sub>prim</sub> was dependent on dose distribution specified by the differential dose volume histogram. For bladder, the ratio between EQD<sub>2 (out PTV)</sub> to EQD<sub>2 (in PTV)</sub> was 29.9:1 for CK-SBRT in contrast to 6.5:1 for 3D-CRT (Table 5.2). The greater OED<sub>prim</sub> obtained for CK-SBRT plan (i.e. 1.14 times larger than 3D-CRT) was the result of larger percentage of bladder volume being exposed to low doses spread by CK-SBRT technique. Risk of RISM at low doses was defined by the linear portion of the LP model. In contrast, more bladder volumes, by 3D-CRT plan, were included in the treatment field where RISM was decreased by increasing dose as defined by the downward part of the LE model. For rectum, differences in dose distributions for these plans followed the same trends as in the bladder. But OEDs from these plans did not differ significantly. By inspecting the dose distribution between out-of-field and in-field, the magnitude of difference in dose distribution observed for CK-SBRT and 3D-CRT was less than what recognized for the bladder (Table 5.3).

Longer beam-on time, larger number of MUs required for CK-SBRT generated a 2.1 fold higher scatter/leakage dose than 3D-CRT. The scatter/leakage

dose is associated with the amount of MUs in a linear function [43]. In terms of OED, longer beam-on time operated for CK-SBRT, on average, caused a 1.6 fold increase in scatter/leakage OED to all organs under study.

Modern radiotherapeutic units employ radiographic imaging for different purposes and importing different doses to patients. CK-SBRT imaging serves to guide tumor targeting by tracking organ motion while 3D-CRT in this study employs imaging to verify field and setup procedures. Imaging doses to region/organs in this study were observed to vary according to the number of images taken for the whole treatment. For PTV, estimates of  $OED_{\text{image}}$  for CK-SBRT and 3D-CRT were comparable. In bladder, the  $OED_{\text{image}}$  for CK-SBRT was 2.2 folds greater than 3D-CRT, while in rectum the  $OED_{\text{image}}$  was only 66% of  $OED_{\text{image}}$  from 3D-CRT.

In overall,  $OED_{\text{prim}}$  was the major component of  $OED_{\text{T}}$  (with > 95% contribution), followed by  $OED_{\text{image}}$  (between 1-4% contribution) and  $OED_{\text{scatter/leakage}}$  (< 1% contribution). Thereby,  $OED_{\text{T}}$  for PTV from CK-SBRT plan was 1.4 folds less than that from 3D-CRT plan. In bladder, CK-SBRT treatment caused a 1.2 fold increase in OED as compared to 3D-CRT. In rectum, estimates of  $OED_{\text{T}}$  for both treatment plans were comparable.

OED concept proposed by Schneider et al [25] is an index used for assessing the carcinogenic impact of radiotherapy. OED is proportional to absolute risk estimate. In converting OED into an absolute risk estimate, excess absolute risk (EAR), requires two additional parameter:  $\beta$ , the initial slope in the unit of excess cases per 10,000 person Gy and  $\mu$ , the population dependent variables specified for age at exposure and age attain [44, 45]. Data used for estimation of  $\beta$  and  $\mu$  are the combination of the Japanese A-bomb survivor data and the secondary cancer data of Hodgkin's patients from the Western population. Although a risk transfer between Japanese and Western populations had been performed. It is advised by Schneider et al [44, 45] that EAR estimates thus obtained must be viewed with care, since the errors involved are large. For the interest to know whether a treatment modality is better than the standard treatment modality with respect to cancer induction in one patient, evaluation of the risk ratio based on OED ratio is considered sufficient.

Despite the fact that larger MUs employed by modern radiotherapeutic techniques such as CK-SBRT cause the significant larger scatter/leakage OED in

comparing to 3D-CRT, but the risk is negligible small. In addition, the doses of imaging procedures during the radiotherapy process, which increase dose in patient. However, the increase in risk is tiny compared to the benefit of treatment.

## CHAPTER VII

### CONCLUSIONS

1. Primary beam component, OED for PTV from CK-SBRT plan was 1.43 times less ( $p \ll 0.0001$ ), while the OED for bladder was 1.14 times ( $p = 0.001$ ) more than those of 3D-CRT. For OED of rectum was not significant difference between the two treatment plans ( $p = 0.284$ ).

2. For scatter/leakage component, The OED for PTV, bladder and rectum from CK-SBRT plan was significantly greater than from 3D-CRT plan ( $p \leq 0.036$ ).

3. Imaging doses component, OED for bladder from CK-SBRT technique was significantly greater from 3D-CRT technique ( $p = 0.0001$ ) whereas OED of rectum was lower ( $p = 0.0004$ ). No significant difference between two treatment techniques was observed for OED of PTV.

4. Overall, total OEDs for PTV generated by CK-SBRT (1.83 Gy) was 1.41 times less than that (2.58 Gy) of 3D-CRT ( $p \ll 0.0001$ ). In contrast, total OEDs of bladder generated by CK-SBRT (6.09 Gy) was 1.17 times greater than that (5.22 Gy) of 3D-CRT ( $p = 0.0005$ ). For rectum, No significant difference between two treatment plans ( $p = 0.346$ ).

5. Primary OED is a major part of total OEDs ( $> 95\%$  of total OEDs), followed by image OED and scatter/leakage OED.

## 1. TLD-700 preparation

### 1.1 TLD-700 calibration

The processes of TLD-700 calibration were:

i) Anneal all 197 rods of TLD-700 with annealing program at 400 °C for 1 hour and 100 °C for 2 hours to eliminate the residual signal in the TLDs.

ii) TLDs were placed in a perspex phantom and irradiated by the cobalt-60 machine to achieve a dose of 0.5 Gy. The exposed TLDs were heated with preheating program at 100 °C for 10 minutes to eliminate off-peak noise before reading the nanocoulomb (nC) by the TLD reader.

iii) Determine the element correction coefficient ( $ECC_i$ ) for each TLD which described by equation 11, and select 15 of all TLDs which had the  $ECC_i$  value closest to 1 used for the TLD calibrations.

$$ECC_i = \frac{\bar{Q}}{Q_i} \quad (11)$$

Where  $\bar{Q}$  is the average charge of all TLD rods and  $Q_i$  is the individual reading of each TLD.

iv) Anneal and irradiate the selected TLDs from (iii) with a dose of 0.5 Gy from the cobalt-60 machine which repeat step (i) and (ii). The corrected charge integral ( $Q_{ci}$ ) of these group was calculated by equation 12.

$$Q_{ci} = Q_i \times ECC_i \quad (12)$$

v) The average value of the  $Q_{ci}$  from (iv) was used for the calculation of the reader calibration factor (RCF) for the whole set of TLDs which defined by equation 13.

$$RCF = \frac{\bar{Q}_c}{D} \quad (13)$$

Where  $\overline{Q_c}$  is the average value of the  $Q_{ci}$ , and D is the known dose in gray (Gy) which was 0.5 Gy.

vi) Anneal and irradiate the rest of TLDs (182 rods) with a dose of 0.5 Gy from the cobalt-60 machine which repeat step (i) and (ii). Calculated the individual element correction coefficient ( $ECC_{ci}$ ) according to equation 14.

$$ECC_{ci} = \frac{RCF \times D}{Q_i} \quad (14)$$

Where D is known dose (0.5 Gy) which irradiated to TLDs and  $Q_i$  is the individual reading of each TLD

vii) The  $ECC_{ci}$  value for each TLD was used to determine an unknown dose ( $D_u$ ) according to equation 15.

$$D_u = \frac{Q_i \times ECC_{ci}}{RCF} \quad (15)$$

Where  $Q_i$  is the individual reading of each TLD from measurement in Rando phantom.

In this study, the  $ECC_i$  value of 197 rods ranged from 0.9059 to 1.2477. These variations were within the acceptable range as recommended in manual (0.7-1.3) [46]. The reader calibration factor (RCF) for the whole set of TLDs was 4560.89708 nC/Gy with the  $ECC_{ci}$  value for each TLD used to convert the reading in nC of each TLD to absorbed dose. The  $ECC_i$  and  $ECC_{ci}$  value were shown in Tables A.1-A.2

**Table A.1 The element correction coefficient ( $ECC_i$ ) value for TLD-700.**

\* The TLDs selected for calibration.

## 1.2 Linearity test of TLD-700

The linearity of 197 rods were evaluated by irradiate with dose of the cobalt-60 machine for 0.05, 0.1, 0.25, 0.5 and 1 Gy, respectively. The readings of all TLDs from each dose were converted into the unit of dose. The average doses obtained from TLDs were plotted as a linear function of the irradiated values. In this study demonstrated a linear relation with a  $R^2$  of 0.9999 which shown in Figure A.1

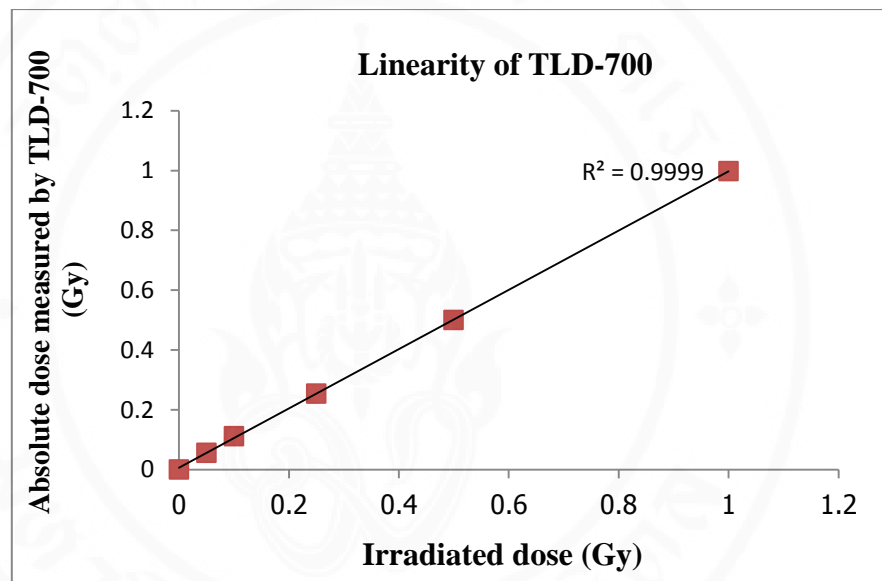

Figure A.1 The linearity of TLD-700.

## 2. TLD-100H preparation

### 2.1 TLD-100H calibration

The processes of TLD-100H calibrations were:

- i) Anneal 100 chips of TLD-100H with annealing program at 240 °C for 10 minutes to eliminate the residual signal in the TLDs.
- ii) TLDs were placed in a perspex phantom and irradiated by the cobalt-60 machine to achieve a dose of 0.1 Gy. The exposed TLDs were heated with preheating program at 145 °C for 10 seconds to eliminate off-peak noise before reading signal by the TLD reader.

iii) Determine the element correction coefficient ( $ECC_i$ ) for each TLD by using the previously mentioned equation 11, and select 10 of all TLDs which had the  $ECC_i$  value closest to 1 used for the TLD calibrations.

iv) Measured the exposure in air with a 6 cc ionization chamber and Accu-Pro™ Radcal (model 9660A) by using 120 kV, 10 mAs (100 mA, 100 ms), then converted to absorbed dose ( $D_w$ ) by equation below.

$$D_w = M \times N_K \times B_w \times [(\bar{\mu}_{en}/\rho)_{air}^w]_{air} \quad (16)$$

Where  $M$  is the exposure reading in mR, exposure calibration factor ( $N_K$ ) was 1, backscatter factor ( $B_w$ ) was 1.21 and  $[(\bar{\mu}_{en}/\rho)_{air}^w]_{air}$  was 1.0297 at HVL = 5.145 mm Al.

v) The selected TLDs (10 chips) were annealed and exposed with 120 kV, 10 mAs (100 mA, 100 ms). Calculated the corrected charge integral ( $Q_{ci}$ ) of these groups, and then calculated the reader calibration factor (RCF) for the whole set of TLDs with 0.487 mGy of dose.

vi) Anneal and irradiate the rest of TLDs (90 chips) with a dose of 0.487 mGy, then calculated the individual element correction coefficient ( $ECC_{ci}$ ). The  $ECC_{ci}$  value for each TLD was used to determine an unknown dose ( $D_u$ ) according to equation below.

$$D_u = \frac{Q_i \times ECC_{ci}}{RCF}$$

Where  $Q_i$  is the individual reading of each TLD from measurement in Rando phantom.

In this study, the  $ECC_i$  value of 100 chips ranged from 0.9568 to 1.0405. The reader calibration factor (RCF) for the whole set of TLDs was 167.73552 nC/mGy with the  $ECC_{ci}$  value for each TLD used to convert the reading in nC of each TLD to absorbed dose. The  $ECC_i$  and  $ECC_{ci}$  value were shown in Tables A.3-A.4

## 2.2 Linearity test of TLD-100H

TLDs chips were exposed with 120 kV, 5 mAs, 10 mAs, 20 mAs, 30 mAs and 40 mAs, respectively. The readings of all TLDs from each exposure were converted into the unit of dose. Measurement the same exposure with a 6 cc ionization chamber in the same condition of exposed TLDs, and then converted to absorbed dose. The average doses obtained from TLDs were plotted as a linear function of the absorbed dose values. In this study demonstrated a linear relation with a  $R^2$  of 0.9969 which shown in Figure A.2

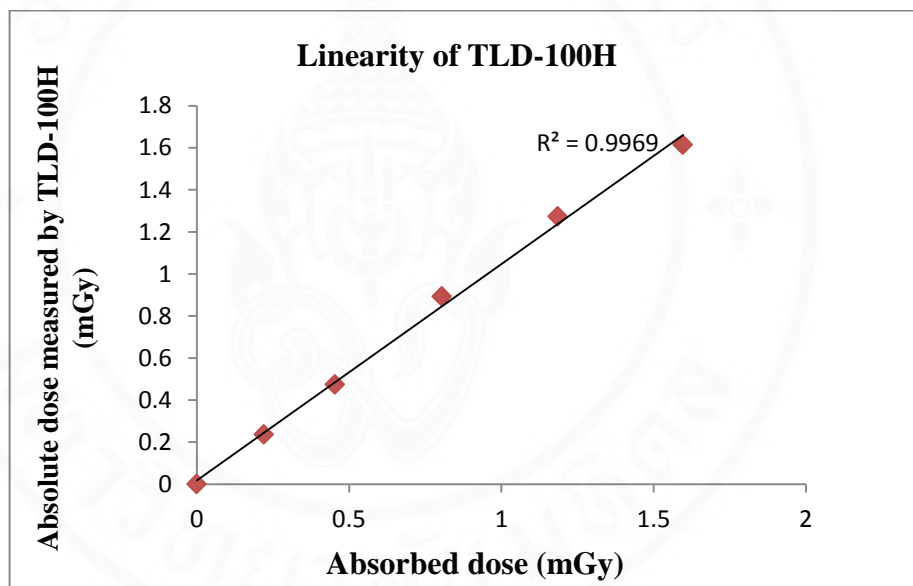

Figure A.2 The linearity of TLD-100H.
