Trading activity of electric energy under electricity markets can be achieved through power pool and bilateral markets. A power pool is generally defined as a centralized market where preferred bids and offers are cleared under a predefined mechanism [1], which is generally performed to maximize social welfare. On another hand, transactions under bilateral markets are contracted based on agreement between a pair of selling and buying entities [2]. During a normal trade, congestion situation may be occurred. In this circumstance, the system operator (SO) needs a CM methodology, which can be classified into congestion relief and congestion cost allocation procedures. The congestion relief is a procedure of utilizing existing means, i.e. generation re-scheduling and load curtailing, to alleviate the overloaded line. The congestion cost allocation is a methodology of allocating the additional cost from the former procedure to participants in a non-discrimination manner. For a power pool, participants sell/buy electric energy according to their nodal or zonal prices, which is formulated based on a spot pricing theory [3]. Transmission services charges, e.g. transmission loss and congestion cost is normally included in both prices. These prices can be calculated using either the objective functions of minimizing the least square of power deviated from the preferred schedule [4] or minimizing the re-scheduled cost [5]. In contrast, under bilateral markets, a dispatching methodology based on contingency constrained together with a minimum number of transaction adjustments is proposed in [6]. In [7, 8], the North American Electricity Reliability Council (NERC) proposes a transmission loading relief (TLR) procedures for bilateral transaction curtailment. Nevertheless, it is argued in [9, 10] that strictly curtailing according to TLR procedures may lead to an unnecessary curtailment. To allocate the congestion cost among bilateral transactions, a power transfer distribution factor (PTDF) is adopted in this regard [11-12]. These schemes [3-12] are basically developed to suit with desired trading arrangement. Unfortunately, due to the co-existence of difference trading arrangements in the same electricity market, implementation of only one CM methodology may not satisfy the whole participants. Therefore, this paper emphasizes on a methodology to manage congestion under a hybrid of power pool and bilateral activities.

In this paper, a complete CM under a hybrid power pool and bilateral market is proposed. In the proposed framework, congestion relief is firstly performed with an objective function to minimize the re-scheduling cost. Then, this cost is allocated among participants in the pool and bilateral market based on their contributions. For a power pool, the allocated cost is a shadow embedded in a nodal price. In contrast, a PTDF is adopted to allocate this cost among bilateral transactions. Others details will be described in related section.

II. TRANSMISSION LINE THERMAL LIMIT MODEL

In this paper, the MVA flow is used as a thermal model in association with π model of a transmission line as shown in Fig. 1.

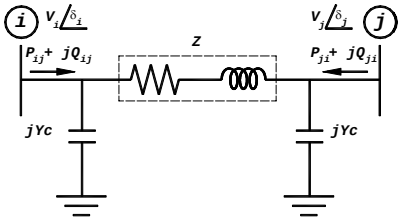

Figure 1 The transmission line model, connected between *bus-i* and *bus-j*

The terms P_{ij} and Q_{ij} are the real and reactive power flowing from *bus-i* $\rightarrow$ *j*, which can be written as (1) and (2) respectively.

$$P_{ij} = V_i V_j Y_{ij} \cos\left(\theta_{ij} - \delta_i + \delta_j\right) - V_i^2 Y_{ij} \cos\theta_{ij} \quad (1)$$

$$Q_{ij} = V_i^2 Y_{ij} \sin\theta_{ij} - V_i^2 Y_c - V_i V_j Y_{ij} \sin\left(\theta_{ij} - \delta_i + \delta_j\right) \quad (2)$$

where V_i, δ_i and V_j, δ_j are the voltage magnitude and angle of *bus-i* and *bus-j* respectively. Y_{ij} and θ_{ij} are the magnitude and angle of elements of bus-admittance matrix at row-*i* and column-*j*, and Y_c is a half of line charging admittance of the line connected between *bus-i* and *bus-j*.

The thermal limit of this line can be represented by apparent power flow in MVA as expressed in (3).

$$P_{ij}^2 + Q_{ij}^2 \le S_{ij}^2 \quad (3)$$

III. Congestion Relief Cost and Procedure

A. Congestion Relief Cost

In case the system operator (SO) dispatches power away from the preferred transactions, reimbursement must be paid to all requested means, which can be described as follow:

- Cost of generation re-dispatching; based on willingness to accept price in case of it is requested to operate away from the preferred value,
- Cost of shedding interruptible load and re-dispatching committed distributed generations, and
- Cost of reactive power from capacitor-banks.

It should be noted that, in case generation is requested to decrease its power it will receive reimbursement less than its bidding price.

B. Congestion Relief Procedure

In our proposed methodology, the congestion relief procedure is formulated in such a way that the congestion relief cost is minimized and all specified constraints are satisfied, which can be described below.

$$Minimize \quad [f]^T [X]$$

$$= \sum_{i \in G,S} C_{G_i} . \Delta P_{G_i} + \sum_{i \in L} C_{L_i} . \Delta P_{L_i} + \sum_{i \in R} C_{R_i} . \Delta Q_{R_i} \quad (4)$$

subject to

$$P_{sch_i} = \sum_{j=1}^{N} P_{ij} \quad (4a)$$

$$Q_{sch_i} = \sum_{j=1}^{N} Q_{ij} \quad (4b)$$

$$S_{ij}^0 + \Delta S_{ij} \le S_{ij}^{max} \quad (4c)$$

$$\sum_{i \in G} \Delta P_{G_i} + \sum_{i \in L} \Delta P_{L_i} + \Delta P_{G_S} = 0 \quad (4d)$$

$$P_{G_i}^{min} \le P_{G_i}^0 + \Delta P_{G_i} \le P_{G_i}^{max} \quad (4e)$$

$$Q_{G_i}^{min} \le Q_{G_i}^0 + \Delta Q_{G_i} \le Q_{G_i}^{max} \quad (4f)$$

$$Q_{R_m}^{min} \le Q_{R_m}^0 + \Delta Q_{R_m} \le Q_{R_m}^{max} \quad (4g)$$

$$V_L^{min} \le V_L^0 + \Delta V_L \le V_L^{max} \quad (4h)$$

where

$[f]$ is a vector of willingness to accept prices of means,

$[X]$ is a row vector of available means,

C_{G_i} is a willingness to accept price of generation at *bus-i*,

C_{L_i} is a bid price of interruptible load at *bus-i*,

C_{R_i} is a reactive power price of capacitor at *bus-i*,

ΔP_{G_i} is the change of generation at *bus-i*,

ΔP_{L_i} is the amount of load curtailment at *bus-i*,

ΔQ_{R_i} is the change of reactive power capacitor at *bus-i*,

ΔV_L is the change of voltage magnitude at load buses.

Subscripts *G*, *L* and *R* represent generation, load and reactive reserve buses respectively, where *N* represents the number of buses. The superscripts *0*, *min* and *max* represent current status, minimum and maximum values of available means respectively.

The objective function of (4) is to minimize the congestion relief cost of available control variables/means as described earlier. Equality constrains of (4a) and (4b) are power flow balance of real and reactive power respectively. Inequality constraint of (4c) is an MVA line flow limit, whereas (4d) is necessary to activate the generation willingness to accept price of a slack bus. Inequalities (4e)-(4g) are traditionally included as acceptable capability limit of control apparatuses, whereas voltage magnitude limit is reflected in (4h).

IV. Congestion Cost Allocation

A. Contributory between Power Pool and Bilateral Markets

Normally, trading volume of power in both power pool and bilateral markets influences to the congested lines. Thus, degree of the contribution between these two markets must be firstly calculated. To cope with nonlinearity of a system, a DC power flow is used, which can be described below.

For a congested line *k*, we assume that a power flow through this line may come from both power pool and bilateral activities, which can be expressed in (5).

$$PF^k = PFPo^k + PFBi^k \quad (5)$$

where

PF^k is a power flow through line *k*,

$PFPo^k$ is a power flow through line *k* from pool market, and

$PFBi^k$ is a power flow through line *k* from bilateral markets.

The term PF^k can be obtained without considering trading arrangement. The terms $PFPo^k$ and $PFBi^k$ can be obtained by treating the trades under bilateral and power pool activities independently.

B. A Nodal Price

A nodal price can be defined as (6).

$$\pi_{p,k} = MCP\left(1 + \frac{\partial F}{\partial p_k}\right) + \rho \frac{\partial H}{\partial p_k} \quad (6)$$

$\pi_{p,k}$ is a nodal price corresponding to the real power injected at *bus-k*; p_k, which can be decomposed into three terms. The first term of (6) is a marginal clearing price; MCP, which is an energy price of buying/selling in a market. The cost of transmission loss that all participants must be paid is the second term. The third term is a congestion charge and it is activated if some transmission line flows are violated. The functions *F* and *H* in general represent a power flow equation

and inequality constraints of a system respectively. The term ρ is a marginal congestion cost.

The term MCP, and marginal clearing quantity (MCQ) can be obtained from a bidding mechanism with objective of social welfare maximization, as shown in Fig. 2.

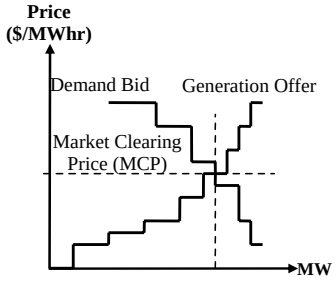

Figure 2 MCP and MCQ of a bidding process

A slack bus is assumed to be a bus of which the last generating unit wins in a bidding process.

C. *Congestion Cost Allocation in a Bilateral Markets*

The term $PFBi^k$ of (5) can be decomposed into (7).

$$PFBi^k = \sum \left(PTDF_{i,j}^k \right) \left(t_{i,j} \right) \quad \forall \quad i \in So, j \in Si \qquad (7)$$

where

$PTDF_{i,j}^k$ is the PTDF of line k for the source at *bus-i* and the sink at *bus-j*, and

$t_{i,j}$ is the amount of power under bilateral contract of source at *bus-i* and sink at *bus-j*.

The terms *So* and *Si* are used to represent source and sink buses of bilateral transactions. Formulation of PTDF can be found in the Appendix.

V. Numerical Results

A. *Test System*

The proposed method is tested with a 6-bus system [13]. Transactions under bilateral markets are shown in Table I.

TABLE I
TRANSACTION UNDER BILATERAL MARKETS

Transaction No.	Generation Bus No.	Load Bus No.	Quantity (MW.)
1	1	4	12
2	1	5	12
3	2	4	12
4	2	6	18
5	3	5	18
6	3	6	18

For simplicity, we assume that loads at buses No. 4, 5 and 6 of 20, 25 and 30 MW are traded in a power pool. According to a bidding mechanism, Generation at buses No. 1, 2 and 3 are selected to dispatch of 16, 20 and 24 MW. In addition generation at bus No. 1 is the last clearing unit with MCP of 10,000 Baht/MW-hr. According to the thereby it is selected to be a slack bus. As a result, power flow result of this transaction can be shown in Fig. 3.

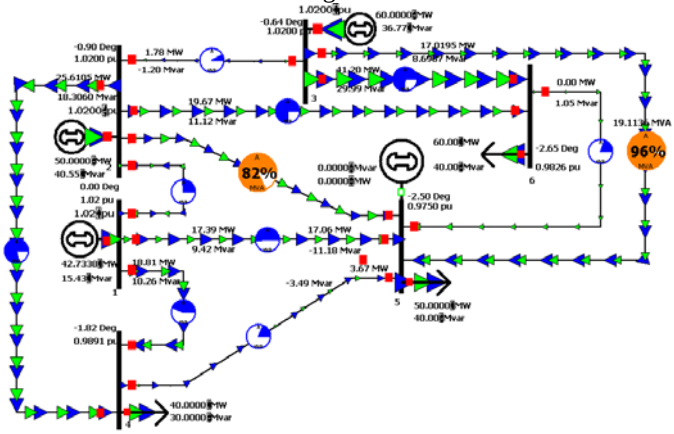

Figure 3 Power flow of a base-case transaction

In practice, entities who can provide means may submit bid to the SO. Then the SO accumulates this information and use them to perform balancing mechanism or congestion management in a spot market. The bidding information is assumed as shown in Table II.

TABLE II
COST OF VARIOUS UTILIZED MEANS WITH THEIR OPERATING LIMIT

No.	Type	Bid Prices (x1000) (Baht/MW-hr or MVar-hr)	Operating Limit Min	Operating Limit Max
1	P_{G_1}	$213.1 + 11.669P_{G_1} + 0.00533P_{G_1}^2$	10	80
2	P_{G_2}	$200.0 + 10.333P_{G_2} + 0.00889P_{G_2}^2$	15	90
3	P_{G_3}	$240.0 + 10.833P_{G_3} + 0.00741P_{G_3}^2$	20	100
4	P_{G_5}	*20*	5	40
5	$L_4\ L_5\ L_6$	*100*	0	10
6	$Q_{R_4}\ Q_{R_5}\ Q_{R_6}$	*100*	0	20

We further assume that close to real time 4 lines are tripped as shown in Fig. 4.

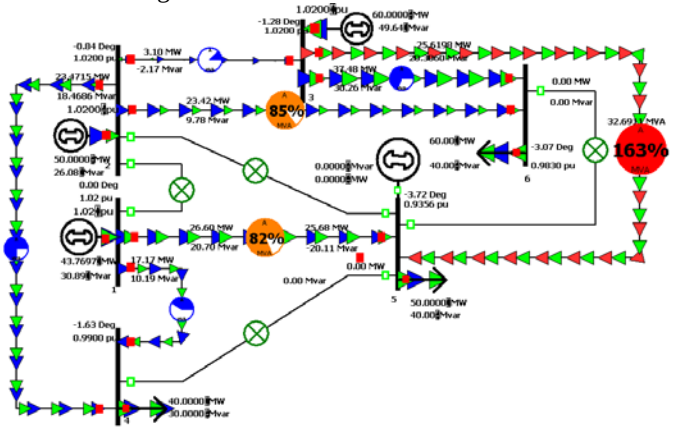

Figure 4 Post-outages power flow result

As a result, 63% overloading occurs at the line connected between buses No. 3 and 5. After the congestion relief procedure is performed, its solution can be shown in Fig. 5.

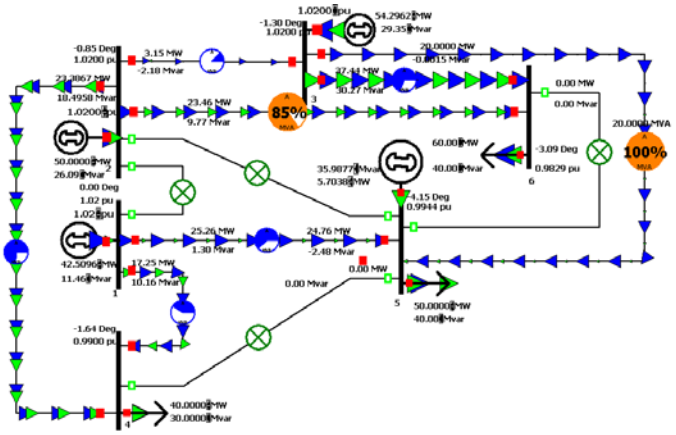

Figure 5 Power flow result after perform the congestion relief procedure

From the method presented in section IV, the minimized congestion cost of Fig. 5 is 127,380 Baht, which is 50,592 and 76,428 Baht responsible by power pool and bilateral markets respectively. The nodal prices of a power pool market are shown in Table III. The congestion cost allocated among bilateral transactions can be shown in Table IV.

TABLE III
COMPONENTS OF NODAL PRICES

BUS NO.	*MCP*	$MCP.\frac{\partial F}{\partial p_k}$	$\rho\frac{\partial H}{\partial p_k}$	NODAL PRICE
1	10,000	0	0	10,000
2	10,000	81	698	10,779
3	10,000	7	1,010	11,017
4	10,000	170	-460	9,710
5	10,000	442	1,289	11,731
6	10,000	202	-911	9,291

TABLE IV
ALLOCATED COST FOR BILATERAL TRANSACTIONS

TRANSACTION NO.	DC PTDF	CONTRIBUTORY DEGREE (%)	ALLOCATED COST (BAHT)
1	-20.07	0	0
2	30.11	19.07	12,146
3	10.04	6.36	4,051
4	-9.12	0	0
5	73.91	70.23	44,729
6	4.56	4.33	2,758

VI. CONCLUSIONS

A CM methodology of a hybrid power pool and bilateral markets is proposed in this paper. A spot pricing theory is used to charge all participants of a power pool. A PTDF is adopted to allocate this cost among bilateral transactions. Various means are considered together with a MVA thermal model. It is tested with a 6-bus system with satisfied results.

APPENDIX

Generation shift factor for *line l* connected between *bus-i* and *bus-j* to changed power at *bus-g* can be shown in (A1).

$$GSF_{l,g} = \frac{1}{x_{ij}}\left[X_{ig} - X_{jg}\right] \qquad \text{(A1)}$$

PTDF of a real power flow through line *l* from transaction of source at *bus-g* and sink at *bus-d* can be expressed as below.

$$PTDF^{l}_{g,d} = GSF_{l,g} - GSF_{l,d} \qquad \text{(A2)}$$

Substitute (A1) into (A2) result in (A3).

$$PTDF^{l}_{g,d} = \frac{1}{x_{ij}}\left[\left(X_{ig} + X_{id}\right) - \left(X_{jg} + X_{jd}\right)\right] \qquad \text{(B9)}$$

Abstract-Fault diagnosis in a transmission system is a process to identify faulted components using the postfault statuses of the protective relays and circuit breakers. However, it is not always easy to do so because the system operator has to quickly analyze a large number of messages and alarms transmitted to the control center to draw a conclusion for which a proper action can be taken to restore the system. Therefore, the system operator needs analysis tools to provide assistance in interpreting the data. This paper proposes a method to solve the problem of locating faults that occur randomly anywhere in transmission systems. The method is based on fuzzy relation that utilizes information on operating time sequences of the actuated relays and tripped circuit breakers, and fault tree that can efficiently handle circuit breaker failure. The method is versatile in that uncertainties, such as protective relay failure, circuit breaker failure are taken into consideration. The method is applied to a 6-bus system. The results show that not only can a fault component be precisely identified but also the problem of loss of alarm data in relays can be solved.

Keyword: Fault diagnosis, Alarm Processing, Expert systems, Fuzzy relation, Fault tree analysis.

I. INTRODUCTION

Every component in a power system is subject to a fault. A fault in a power system must be isolated as quickly as possible because it affects the reliability and security of the system. When a fault occurs, the fault section must be detected and removed from the rest of the system thorough the series of relay and circuit breaker operations [1]. However, the identification of faults is a time consuming and complex task because a large amount of data obtained from monitoring devices needs to be analyzed to ascertain whether the relevant protection schemes responded correctly. Other constraints are some false operations of relay and circuit breakers, inexperienced system operators, and simultaneous faults with different locations. Therefore, a system operator needs analysis tools to provide assistance in interpreting the data and comes with a critical piece of information.

A number of methods have been proposed such as artificial neural network [2]. Of these, the expert system is the most established. For example, Pseudo-relaxation method is a fast iterative learning algorithm combined with neural network to find a solution [3]. However, it is computationally expensive for a large-scale system, and in some cases, it may not converge to a solution. An expert system based on "If-Then-Rule" also has a limitation on designed rule-base that cannot cover all possible situations. In other word, the expert system can perform satisfactorily only for those situations that have been considered during the development of knowledge base. An expert system based on fuzzy relation was proposed in [4]. The paper ranks fault section candidates in terms of the degree of membership and the malfunction or wrong alarm. This method provides more flexibility than conventional expert system methods. However, circuit breaker failure are not taken into account.

This paper proposes a technique for fault identification in transmission systems for alarm processing by fault tree analysis and fuzzy relation. The proposed method is able to deal with circuit breaker failure. The method builds a sagittal diagram for each of the components to represent operating conditions of the relays and circuit breakers during a fault. The degree of membership of is then calculated by fuzzy arithmetic. This degree of membership will be used to determine the maximum likelihood of the fault location. The paper is organized as follows. Section II describes the basic principle for SCADA. Protective systems emphasizing on transmission networks are given in Section III. Sagittal and fuzzy relations are described in Section IV. Section V details fault tree analysis. Section VI shows a case study for a 6-bus power system. Section IV concludes the paper.

II. SCADA SYSTEM IN CONTROL CENTER

SCADA stands for supervisory control and data acquisition. It is used to monitor or to control the system equipment in remote areas. SCADA has a capability of checking the statuses of the system equipment (e.g., relay, circuit breaker) and data (e.g., current, voltage) and reporting them back to the control center. A SCADA system has proven to be efficient and economical for power system operations, making it possible for them to maintain relatively complete knowledge of condition and the portions of the system for which they are responsible [5]. In general, SCADA consists of control center, remote terminal units (RTU) and communicating system. A typical SCADA system in a control power system is shown in Fig. 1.

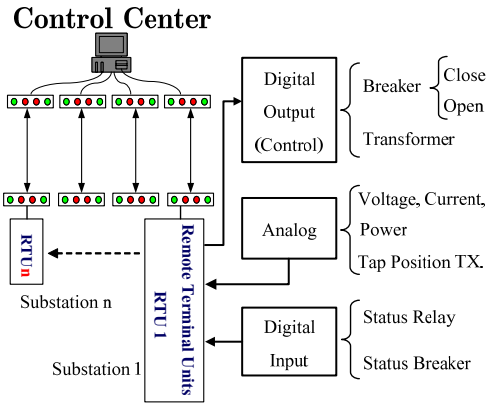

Figure 1. Configuration of SCADA in control center

III. Protection System

The basic function of the relay is to detect a faulted element and remove it, with the help of circuit breaker, from the remaining healthy system as quickly as possible so that as much as the rest of the system is left to continue service and to avoid damage and maintain security or reliability of supply

A protective relay is a device that senses a fault, determines the fault location, and sends tripping command to the proper circuit breaker. A fault may not be cleared if the circuit breaker fails to open or relay malfunctions. In such case, the fault is cleared by backup protection. This situation will not favor the system operator as it makes the data interpretation more difficult to be analyzed to find the fault location.

Differential and distance relays are widely used for the protection of transmission systems because the relays are more effective than overcurrent relays. Differential relays detect abnormal conditions in the area for which they are responsible. They are often used to protect busbars and transformers. Distance relays, in general, protect transmission line in three zones: zone 1 covering 100% of line impedance with instantaneous operation, zone 2 covering 80% with time delay and zone 3 covering 120-150% with time delay.

For example, in Fig. 3 [6] above, CB1 and CB2 are the protection devices of L1. The primary relays are L1AZ1 and L1CZ1 and the backup relays are L1AZ2, L1AZ3, L1CZ2, and LICZ3. When a fault occurs at L1 and is cleared from the system, the alarm messages of CB-01, CB-02, L1AZ1, and L1CZ1 are shown in the control center. If L1CZ1 (Zone 1) fails to operate, L1CZ2, the back-up protection, will respond instead or if L1CZ1 and L1CZ2 do not take any action, the backup protection in Zone 3 will realize that, thus L2BZ3 and L3DZ3 providing the back-up.

IV. Sagittal and Fuzzy Relations

Sagittal diagrams represent the fuzzy relations for power systems and diagnose fault sections using the operation in fuzzy relation [4]. A sagittal diagram has a three set of layers that describe the relationship of fault section (first layer), relay (second layer), and circuit breaker (third layer). In each layer, there are nodes representing the appropriate device. The interconnection between the nodes in each layer is determined from the normal operations of relays and circuit breakers in the occurrence of fault, and the causality is denoted by arrow.

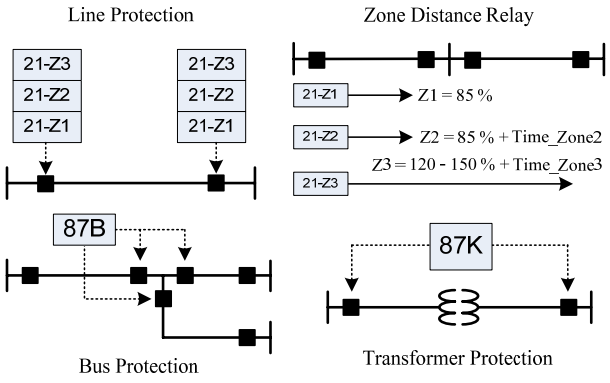

Figure 2. Protection systems

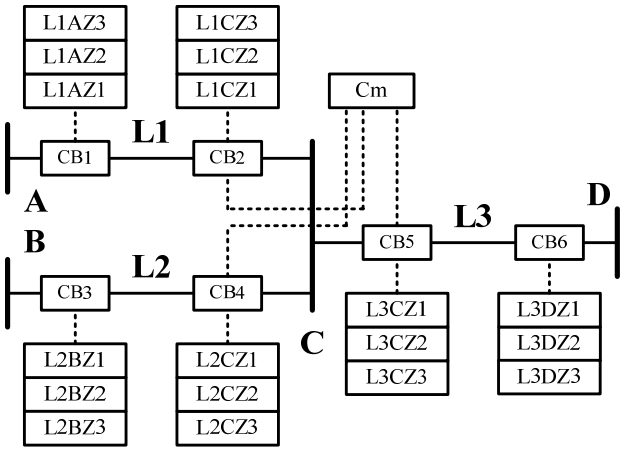

Figure 3. 4-bus power system

For example, the sagittal diagram of L1 is shown in Fig. 4. The label on a line is statistically determined considering the uncertainty of operation and the priority of relays and circuit breakers. The value of a label is between 0 and 1. A label of 0.9 on the line L1AZ1-CB1 indicates that if CB1 operates, a chance of 90% is due to the command from L1AZ1. A label of 0.8 on the line L1-L1AZ1 indicates that if relay L1AZ1 responses, the likelihood of the fault on L1 is 80%. With this method, uncertainty can be taken into account instead of the "If-Then" rule, which can only give the answer "yes (1)" or "no (0)". Note that nodes CB3 and CB6 in the figure will be considered only when CB2 is not tripped as they are served as a backup protection.

The algorithm to find degree of membership for each of the system component from fuzzy relation consists of the following steps.

Step 1: Draw sagittal diagrams of all the devices. For example, there are four sagittal diagrams, L1, L2, L3, and Bus C, for the network in Fig. 3.

Step 2: Find the path that links layer 1, layer 2 and layer 3 in each sagittal diagram. The path is determined from relays

and circuit breakers alarmed. From Fig. 4, path 1 is L1-LICZ1-CB2 and path 2 is L1-L1AZ2-CB1.

Step 3: Calculate the fuzzy relation intersection for each path by

$$i_w(a,b) = 1 - ((1-a)^w + (1-b)^w)^{\frac{1}{w}} \quad (1)$$

Where
a = label on a line connected between layers 1 and 2
b = label on a line connected between layers 2 and 3
w = weight factor of Yager's family of operators [7]

The parameter w is positive number. A weight factor of 3 is used in this paper.

Step 4: Calculate fuzzy union for each sagittal diagram by (2).

$$u_w(a,b) = (a^w + b^w)^{\frac{1}{w}} \quad (2)$$

Step 5: Choose the maximum value of u_w in each sagittal diagram. This value indicates the maximum likelihood of a faulted component.

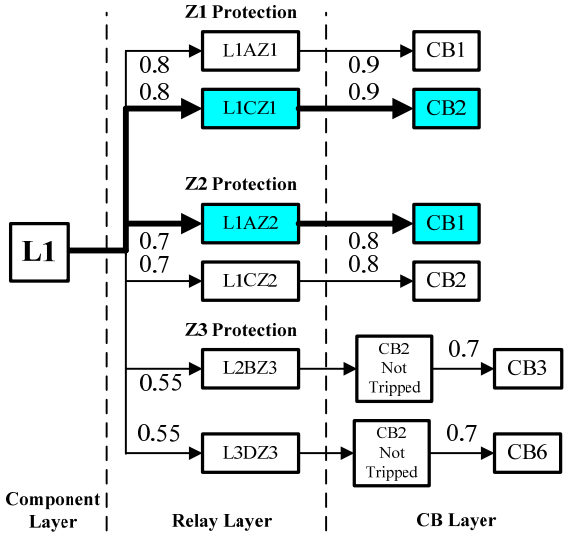

Figure 4. Sagittal diagram of line1

V. Fault Tree Analysis

The event of circuit breaker failure makes it difficult to analyze the faulted component because the backup protection is involved in the investigation. To overcome that problem, this paper introduces fault tree analysis (FTA), which is a top-down approach that utilizes the statuses of the circuit breakers and protective relays as an indicator. The advantage of FTA is that it provides a good, diagrammatic connection of events, as shown in Fig. 5. The symbol ▭ stands for a further-analyzed event and ○ for a terminal event. The connection between events can be represented by the symbols ∩ or ∪. Fig. 5 shows that CB2 fails owing to the following three sub events: the protection of CB2 operates, CB2 closes after receiving command from relay and zone 3 of other transmission lines sees and clears the fault (i.e., L2, L3).

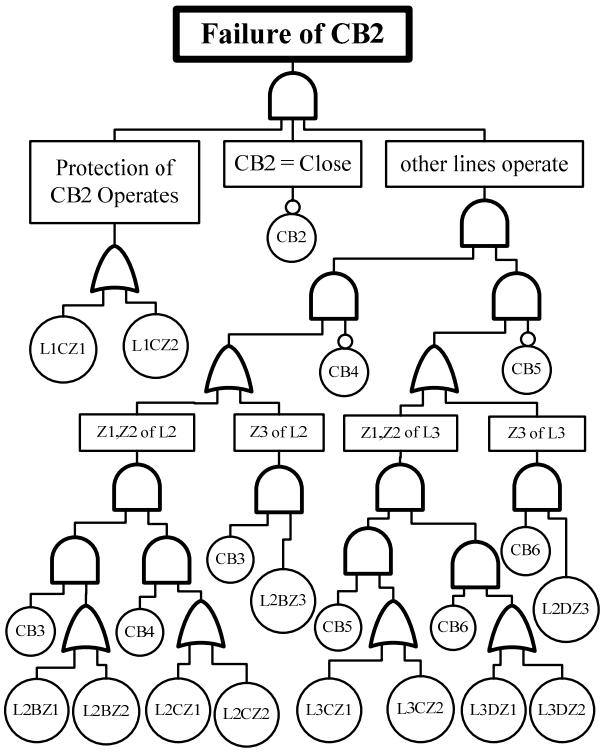

Figure 5. Fault tree analysis for failure of CB2

VI. Case Study

A computer program was developed on MATLAB and tested with a system modified from Fig. 3 by adding buses, and transmission lines to make it more complicated. The test system is shown in Fig. 6, consisting of 6 buses, 7 transmission lines and 14 circuit breakers. Table I shows the input of the case study, which contains 9 scenarios. The scenarios cover various events such as multiple faults, circuit breaker failure and alarm of relay not shown at the control center. The outputs are faulted components and circuit breaker failure. Note that 03 in Table I represents circuit breaker No.3 and 121 represents a distance relay of L1 close to bus 2 in protection zone 1. Table II shows the simulation result for each scenario. It is clearly seen from each scenario that the developed program is able to correctly identify the faulted components and the circuit breaker failure obtained from FTA. The computation time for each scenario is less than 1 second, confirming the efficiency of the method. The diagnosis detail for each scenario is given in Table III. The results of all the scenarios are graphically shown in Fig. 7.

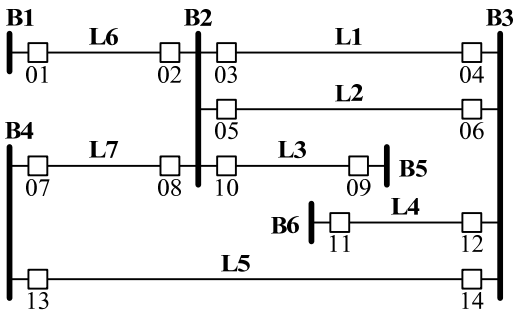

Figure 6. 6-bus test system

TABLE III
DIAGNOSIS DETAIL OF EACH SCENARIO

Scenario	Diagnosis Detail
1	Fault at L1 + failure of Z1 protection of CB04
2	Fault at L1, L2
3	Fault at L3, Bus2
4	Fault at L3, Bus2 + alarm of 351 not shown
5	Fault at L1, L2 + alarm of 131 not shown
6	Fault at L1, L2 + failure of CB03
7	Fault at L1, L2 + failure of CB06 + alarm of 221 not shown
8	Fault at L1, L3 + failure of CB03 + failure of CB10
9	Fault at L1, L2, L5 + alarms of 121 and 231 not shown

VII. CONCLUSION

The main advantage of fuzzy relation and expert system presented in this paper is the reduction of complexity in creating rule base by using the sagittal diagram. The method can efficiently solve the problem of loss of alarm for relays. This paper also introduces fault tree analysis to deal with the problem of circuit breaker failure. The case study performed has shown that a fault location can be precisely identified within a short period of time, indicating a promising result to help the system operator in decision making for real time operation. Future work is the application of the proposed method to a more complex, large-scaled system and to a variety type of relays, for example transformer differential relay, recloser relay and overcurrent relay.

Analysis of Substation Ground Grid for Ground Potential Rise Effect Reduction in Two-Layer Soil

A. Puttarach, N. Chakpitak , T. Kasirawat and C. Pongsriwat

***Abstract*--**This paper presents an effects of ground grid and ground rods on grounding performance in a two-layer soil structure with a low resistivity top layer for ground potential rise (GPR) effect reduction. When the grid is completely buried in the low resistivity top layer, its GPR is gradually reduced depend on the buried depth level. On the contrary, when the grid is buried in the high resistivity bottom layer, its GPR is more gradually reduced. A GPR comparison of ground grid with rod and without rod is done, the result shows that the GPR is significantly reduced when the rods are especially applied with the grid in the high resistivity bottom layer.

Index Terms -- **Ground Potential Rise, Resistivity, Ground Rod, Ground Grid, GPR, CDEGS.**

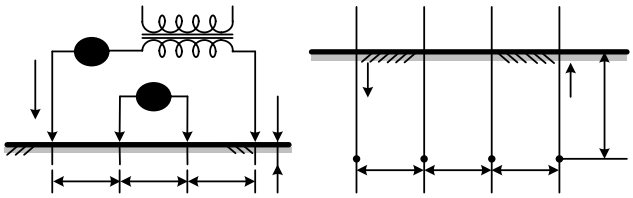
I. Introduction

The effect of fault-produced ground potential rise can directly result in a mistaking operation, damaging of equipment or human safety [1]. Normally, the magnitude of the GPR depends upon such factors as the impedance to ground of the substation grounding system and the fault current [2]. Ground resistivities are also the most important factor to GPR analysis, typically, actual resistivities tests are imperative and should be made within the site to determine the soil layer [3]-[9].

In this paper, from the different characteristic of soil structure particularly in two-layer soil, the influence of variations in depth of ground grid is investigated. Commonly, ground grid buried in top layer or bottom layer of two-layer soil gives distinct result in GPR because of the different of soil resistivities in both layers. Therefore, in this study, the performances of ground grid buried in each layer depth are done to select whose layer is proper to bury. Moreover, consideration of soil layer depth is also the most important in substation ground grid design.

II. Resistivity Measurements

The most frequently used method to determine the soil resistivity depth is the four-point method. Also called *Wenner method* (as shown in Figure 1). The four rods are arranged with the same spacing *a*, five measurements with the spacing a = 2 m, 4, 8, 16 and 32 m are carried out, *b* is the depth of the electrodes in m. For each measurement a current I is injected between the probes C_1 and C_2 and the voltage between P_1 and P_2 is measured [10].



(a) (b)

Fig. 1 (a) Principle diagram of an earthing tester**.**
(b) Current injection into the soil**.**

The resistivity ρ in the terms of the length units in which *a* and *b* are measured is:

$$\rho_a = \frac{4\pi aR}{1+\frac{2a}{\sqrt{a^2+4b^2}}-\frac{a}{\sqrt{a^2+b^2}}} \quad (1)$$

It should be noted that this does not apply to ground rods driven to depth *b*; it applies only to small electrodes buried at depth *b*, with insulated connecting wires. However, in practice, four rods are usually placed in a straight line at intervals *a*, driven to a depth not exceeding 0.1 a. Then we assume *b* = 0 and becomes [2]-[3]:

$$\rho_a = 2\pi aR \quad (2)$$

And gives approximately the average resistivity of the soil to the depth *a*.

III. Two-Layer Soil Apparent Resistivity

A resistivity determination using the Wenner-method (see Figure 2) result in an apparent resistivity which is a function of the electrode separation, *a* In terms of the above parameters the apparent resistivity (ρ_a) can be shown to be:

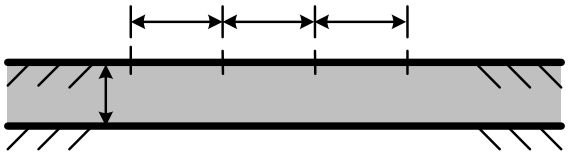


Fig. 2 Two-Layer Earth**.**

Where

h First layer height.

ρ_1 First layer resistivity, in Ω.m

ρ_2 Deep layer resistivity, in Ω.m

$$\rho_a = \rho_1 \left(1 + 4 \sum_{i=1}^{\infty} \frac{K^n}{\sqrt{1+\left(2n\frac{h}{a}\right)^2}} - \frac{K^n}{\sqrt{4+\left(2n\frac{h}{a}\right)^2}} \right) \quad (3)$$

A two-layer soil model can be represented by an upper layer soil of a finite depth above a lower layer of infinite depth. The abrupt change in resistivity at the boundaries of each soil layer can be described by means of a reflection factor. The reflection factor , K , is defined by Equation(4) [11].

$$K = \frac{\rho_2 - \rho_1}{\rho_2 + \rho_1} \quad (4)$$

IV. CDEGS Model Of Studied System

The grounding grid system of a practical 22 kV substation, in which the ground grid is made from copper, is calculated by virtue of the CDEGS software (Current Distribution Electromagnetic Interference Grounding and Soil Structure Analysis) [12]. The study, supported by Provincial Electricity Authority (PEA), Thailand, is based on grounding grid system of Royal Flora RATCHAPHRUEK substation. The supporting soil resistivity data has been obtained from field tests at the substation. Models of system studied have been presented as follow.

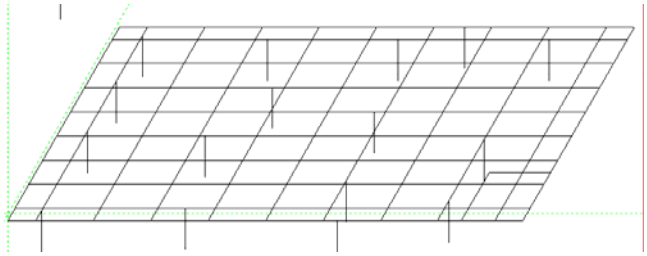

Fig. 3 The grounding grid system of Royal Flora RATCHAPHRUEK substation.

95 mm^2. Hard Drawn Copper Cable.

Exothermic Welding (Graphite Mould).

Copper-Clad Steel Ground Rod.

To study the influence of the soil layer depth in which ground grid is buried to the effect of GPR, ground grid buried at 0.5m below the ground level with 3m rod length is chosen to be the original model in this study , as shown in Figure 3. The following of ground grid characteristics on GPR are investigated:

Case A: Ground grid with constant 3m rod length in variation of soil layer depth, as shown in Figure 4.

Case B: Ground grid without rod in variation of soil layer depth.

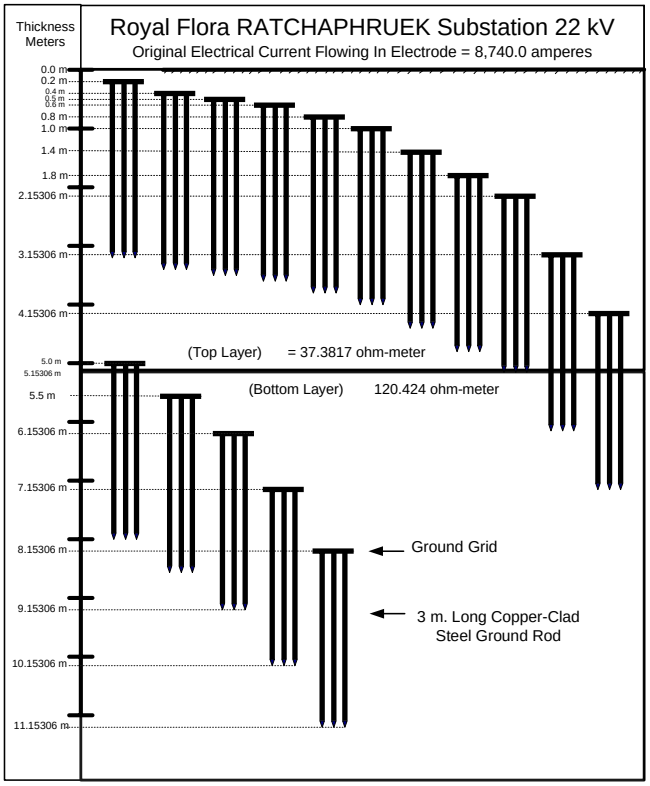

Fig. 4 variation of soil layer depth for ground grid with 3m rod length.

V. Simulation Results

From simulation, the results show the interpreted soil resistivity. Moreover, the ground potential rise of each case is shown. The fault current value 8,740A of PEA fault current report at 22 kV level was utilized in the studies.

A. Soil resistivity results

The resistivities of top and bottom layer are 37.8167 Ohm-m and 120.4224 Ohm-m respectively. The top layer has the resistivity less than the bottom layer (deep layer).

TABLE I

Resistivity of each soil layer (System information summary)

Layer Characteristics				
Layer	Resistivity (Ohm-m)	Thickness (Meters)	Reflection Coefficient(p.u.)	Resistivity Contrast Ratio
Top	37.38167	5.153056	-1.0000	0.37382E-18
Bottom	120.4244	infinite	0.52623	3.2215

Soil layer characteristics were shown in TABLE I, the soil characteristic was interpreted in two-layer model.

The soil resistivity interpretation, which was done by using RESAP module of CDEGS program, is logarithmically manifested in Figure 5.

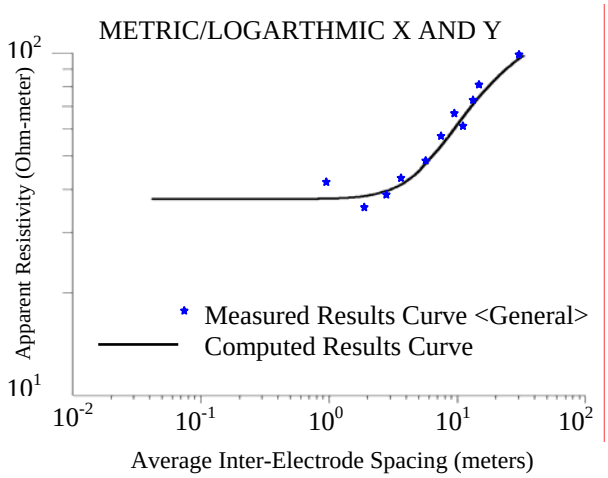

Fig. 5 Soil Resistivity Model.

B. Ground potential rise results

The result of GPR in each case is shown in Table II and the GPR performance in each layer thickness and 3-D of GPR in original case are shown in Figure 6 and 7 respectively

TABLE II
Substation Ground Potential Rise

Layer Thickness (m)	GPR Comparison with Remote Ground (V)		GPR Difference between Point C1 & C2 (V)	
	case A	case B	case A	case B
0.20000	8,494.3	8,504	390.56	440.50
0.40000	8,415.4	8,485	279.06	312.44
0.50000	8,386.0	8,475	223.57	306.82
0.60000	8,359.2	8,463	218.38	240.00
0.80000	8,312.0	8,436	167.71	182.33
1.00000	8,270.6	8,404	125.76	134.82
1.40000	8,200.9	8,345	72.33	76.73
1.80000	8,144.9	8,258	85.29	91.68
2.15306	8,105.0	8,136	87.80	104.34
3.15306	8,039.6	8,981	101.88	116.76
4.15306	8,020.6	8,416	114.91	131.46
5.00000	8,072.4	8,331	129.79	160.16
5.50000	8,889.7	8,082	155.50	167.32
6.15306	8,997.5	8,623	168.55	172.85
7.15306	9,038.3	8,384	337.08	345.69
8.15306	9,026.9	8,232	328.33	335.43

From case A, as soil layer depth of buried ground grid is varied, the results show that soil resistivities of top-layer is lower than the bottom layer and the GPR is continuously reduced along with the increasing of layer thickness until it reach the boundary of this two-layer

From case B, the ground grid with absence of ground rods buried in each soil layer depth is considered. The results show that the value of GPR is not significantly different from case A, noticeably, ground rod can keep the lower value of GPR in both top and bottom layer, especially in bottom layer.

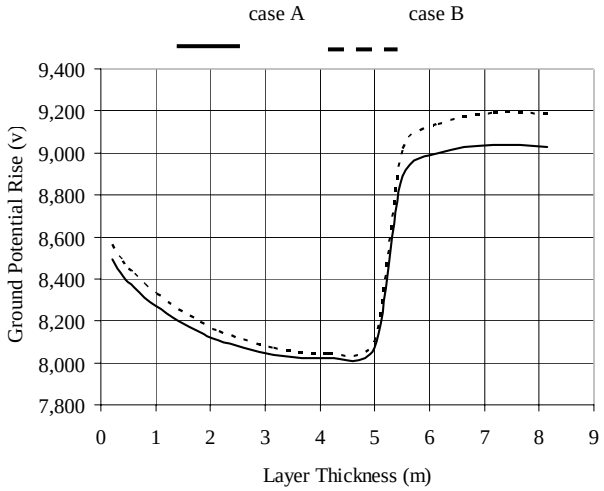

Fig. 6 GPR and layer thickness in each case.

Figure 7 illustrates the GPR of substation comparison with remote ground of ground grid buried in 0.5m depth below the ground plane with 3m rod length. The GPR difference within substation is also compared as seen in Figure 8 between point C1 and C2.

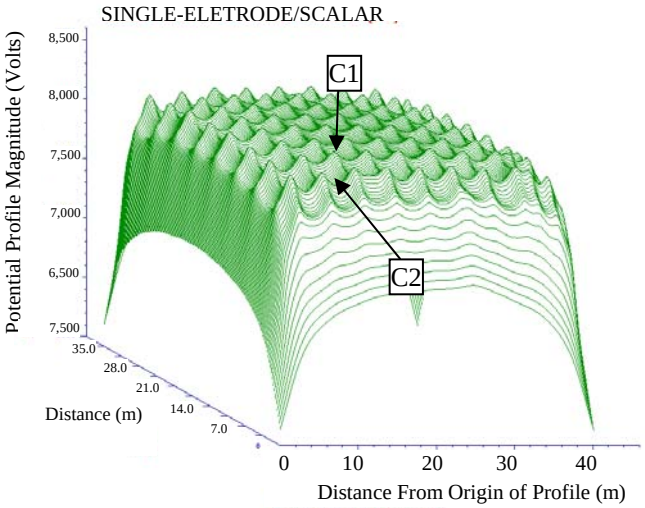

Fig. 7 GPR of ground grid buried in 0.5m depth with 3m rods.

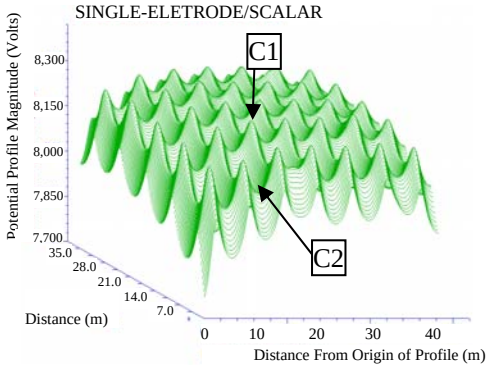
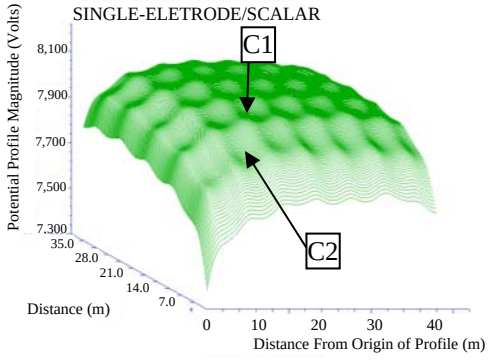
GPR difference between point C1 and C2 was done where C1 is the highest point of GPR and C2 is the lowest point of GPR within substation. The results show that , from case A, at 0.2 m. layer thickness the GPR difference between C1 and C2 is 390.56 V and when the layer thickness increases to 1.4 m. the GPR difference is just decrease to 72.33 V which is the most minimum difference of GPR as shown in Figure 8(a) and 8(b).

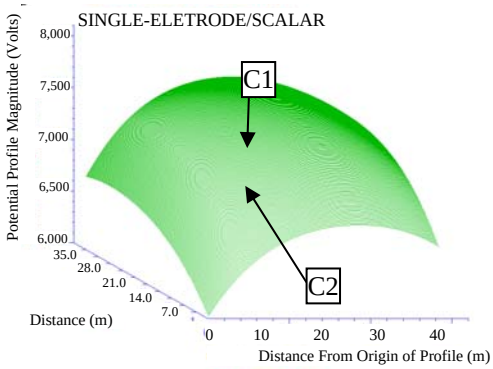
When the ground grid buried in the high resistivity bottom layer, the GPR difference strongly increased compared to the ground grid buried in the low resistivity top layer, besides, the results also accord with the GPR which compared to remote ground.



(a) At 0.5m layer thickness.



(b) At 1.4m layer thickness.



(d) At 6.5m layer thickness.

Fig. 8 GPR Difference between two point within substation.

From the study, ground grid with rod buried in variation of soil layer depth gives outstandingly result in GPR difference reduction within substation and better result of GPR than ground grid without rods.

VI. CONCLUSION

For substation ground grid designs, a factor which should be considered in design phase is the layer of buried ground grid, that is, in case of two-layer soil structure and the top soil resistivities is lower than the bottom soil resistivities, ground grid buried in low resistivities top layer can reduce the GPR more than the ground grid buried in the high resistivities bottom layer. However, the high resistivities of bottom layer does not affect to the reduction of GPR but to the contrary. Finally, the layer thickness of buried ground grid can significantly reduce the GPR difference between two points within substation and bring about the same results with the remote ground GPR comparison.

VIII. BIOGRAPHIES

Arwut Puttarach was born in Chiang Rai. He received his B.Eng, degree in Electrical Engineering from Rajamamgla Institute of Technology Chiang Mai Campus, Thailand, in 2003. He is currently a master degree student in Electrical Engineering, Chiang Mai University, Thailand. His currently interests in power system grounding analysis.

Nopasit Chakpitak received his first degree in Electrical Engineering from Chiang Mai University. His professional career was in Electricity Generating Authority of Thailand between 1989-1994. He has finished his Ph.D in Electrical Engineering in 2003 from the University of Strathclyde Scotland. Now he is a full-time lecturer of department of Electrical Engineering, Chiangmai University.

Tirapong Kasirawat was born in Karbi, Thailand 1963. He received B.Eng (Electrical Engineering) M.Eng (Electrical Engineering) from Chiang Mai University, Thailand, in 1987 and 1995 respectively. Currently, He works with Provincial Electricity Authority, Thailand (PEA North1) and special lecturer of department of Electrical Engineering Chiang Mai University. His research interest includes high-voltage engineering, power quality, and information technology in power system.

Chotepong Pongsriwat was born in Lampang, Thailand 1976. He received B.Eng (Electrical Engineering) , M.S.(Information Technology and Management) and M.Eng (Electrical Engineering) from Chiang Mai University, Thailand, in 1997, 2003, and 2004 respectively. Currently, He works with Provincial Electricity Authority, Thailand (PEA North1). His research interest includes power quality, power system analysis and information technology in power system.

Design of Automatic Generation Control Using the Method of Inequalities

Emails: raksanai@hotmail.com, suchin.a@chula.ac.th and bundhit.e@chula.ac.th

***Abstract*— This paper describes a new design strategy for a multiarea Automatic Generation Control (AGC) system and a procedure for solving it using the method of inequalities. In this strategy, electricity market constraints are taken into consideration in order to increase technical and economical reliability of the system. The design problem is formulated as a set of inequalities in accordance with the multiobjective nature of the problem. As a result, the design can be carried out in an effective way.**

I. INTRODUCTION

Nowadays, electricity market criteria have significant impact in power system operation. The violation of these criteria should be firstly prevented by a proper design of the AGC controller system taking into account the required criteria as constraints. With this design concept, we can increase technical and economical reliability compliance to the power system.

In the past, methods for designing an AGC controller are generally based on optimal control [1][2][3], fuzzy control [4], and state feedback control concepts. However, the mathematical formulation employed by these methods do not easily enable the designers to fulfil all the design requirement. When the design process has been finished, they need to perform simulations on the obtained system so as to check whether the results satisfies all the design criteria. If the system does not satisfy all the criteria, they have to conduct a trial and error process in redesigning the system again. As a result, the design process can be time-consuming.

The method of inequalities [5] gives rise to a formulation in the form of a set of inequalities that represent all the design requirements. After the design process, provided the formulation is accurate and realistic, the designer can see whether the obtained design satisfies all the requirements without having to perform a number of unnecessary simulations for verification. For this reason, we employ the method of inequalities in designing the AGC system.

II. MATHEMATICAL MODEL OF AGC SYSTEM

In this paper, we consider an interconnected power system with two identical control areas. Each area consists of thermal and hydro power generating units. The block diagrams of the system are shown in Figures 1–4 [6][7][8]. The values of the system parameters are given in Table I.

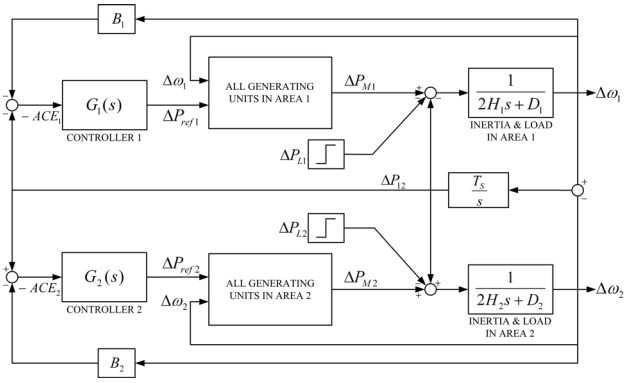

Fig. 1. Two area interconnected AGC model.

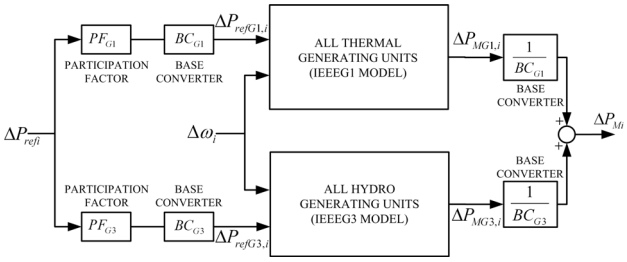

Fig. 2. Model of all generating units of area i.

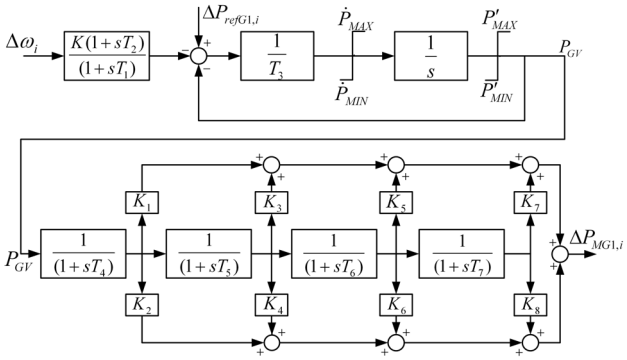

Fig. 3. Thermal generating unit model of area i.

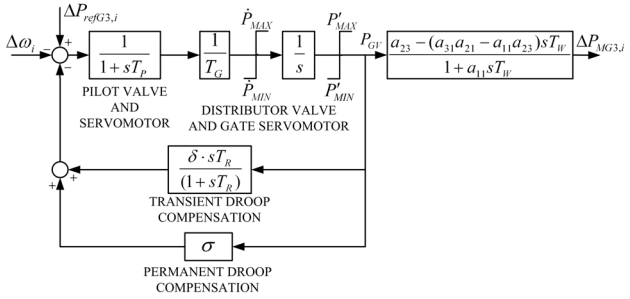

Fig. 4. Hydro generating unit model of area i.

TABLE I
MODEL PARAMETERS

Parameters of all generating unit

$PF_{G1} = 0.75$	$PF_{G3} = 0.25$	$BC_{G1} = 500/400$	$BC_{G3} = 500/70$

Two area AGC parameters

$H_1 = H_2 = 4.1526$	$D_1 = D_2 = 0.9760$	$B_1 = B_2 = 27.3$	$T_s = 2$

IEEEG1 parameters

$K = 20$	$K_1 = 0.3$	$K_2 = 0$	$K_3 = 0.4$
$K_4 = 0$	$K_5 = 0.3$	$K_6 = 0$	$K_7 = 0$
$K_8 = 0$	$T_1 = 0.25$	$T_2 = 0$	$T_3 = 0.1$
$T_4 = 0.3$	$T_5 = 10$	$T_6 = 0.4$	$T_7 = 0$
$\dot{P}_{MIN} = -0.1$	$P_{MIN} = 0$	$\dot{P}_{MAX} = 0.1$	$P_{MAX} = 1$

IEEEG3 parameters

$T_G = 0.2$	$T_P = 0.04$	$T_R = 5$	$T_W = 1$
$a_{11} = 0.5$	$a_{13} = 1$	$a_{21} = 1.5$	$a_{23} = 1$
$\sigma = 0.04$	$\delta = 0.4$	$\dot{P}_{MIN} = -0.1$	$P_{MIN} = 0$
$\dot{P}_{MAX} = 0.1$	$P_{MAX} = 1$		

III. ELECTRICITY MARKETS

Ancillary service [9] generally consists of voltage support, regulation and frequency, energy imbalance, operating reserve and black start capacity services, etc. The energy imbalance service which service balances the interconnection system frequency, called as Direct Frequency Control (DFC). The DFC which is one of the most essential services consists of regulation and load following services.

The primary difference between the regulation and load following service is the time frame of consideration. Regulation service is defined to be the higher frequency of power service following the minute-to-minute load variation, whereas the load following service is intended to follow the lower frequency component of load variation, the time scale of which normally covers period of hours [9].

In this paper, we consider only regulation service as a constraint in the design process of the AGC controller.

A. Regulation Components

In hourly generation scheduling, the boundary between regulation and load following occurs at a frequency with a period length of twice the scheduling period, i.e. two hours [9]. All variation in load with full cycle period less than two hours is considered as part of the regulation service and all variations in load with full cycle periods equal to or greater than two hours are considered as load following service.

A regulation example is shown in Figure 5, comprising total load, smoothed load, and regulation. The regulation component is calculated by using Fourier transforms to decompose

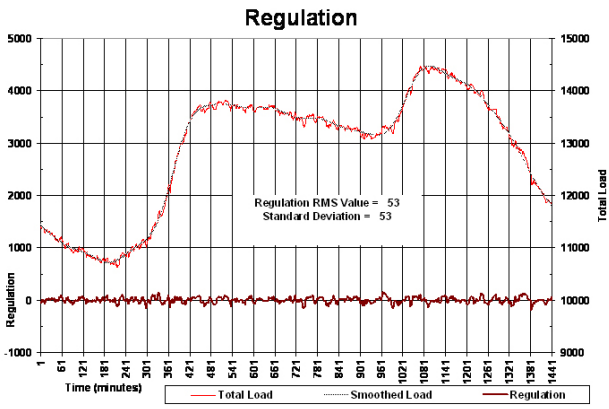

Fig. 5. The regulation component of total load.

the total load into the regulation component and the smoothed load component. With the decomposition in this manner, the regulation component of the load has a net integrated energy of zero. In other words, there is no energy or energy imbalance associated with the regulation component. The root mean square (RMS) value for regulation is also calculated. In this case, since the net integrated energy of the regulation ($\bar{x}$) is zero, then the standard deviation (σ) for regulation has the same value as the RMS. The equations for the standard deviation (σ) and the RMS values can be written as (1) and (2).

$$\sigma^2 = \frac{1}{n}\sum x_i^2 - \bar{x}^2 \tag{1}$$

$$RMS^2 = \sigma^2 + \bar{x}^2 \tag{2}$$

B. Real energy service measurement

The measurement standard presented in [10][11][12] called Control Performance Standard 1 ($CPS1$) uses compliance factor (CF) to measure controller performance of each area. The CF is defined as:

$$CF = \frac{1}{n}\sum \frac{\overline{ACE} * \overline{\Delta F}}{B} \tag{3}$$

where $\overline{ACE}$ is the one minute average ACE and $\overline{\Delta F}$ is average standard error of frequency in one minute. A positive CF means the control area is acting as a burden to the interconnection regulation requirement. On the other hand, a negative CF indicates that the area is supporting the interconnection regulation requirement.

The $CPS1$ is a standard reference for defining capacity and measurement of regulation and load following services. Illiam and Hoffman [10] showed the importance of coincidence between scheduled errors of interconnection systems. Regulation and load following service measurement should use the RMS value combined with coincidence factor as follows:

$$C_{reg}^2 = \frac{1}{n}\sum \overline{\Delta T} * \overline{\Delta F} \tag{4}$$

where $\overline{\Delta T}$ is the schedule error over a of one minute period.

IV. THE METHOD OF INEQUALITIES [5][13]

The method of inequalities [5][13] requires that a design problem be formulated as a set of inequalities:

$$\Phi_i(p) \le C_i, \qquad i = 1, 2, \ldots, m \tag{5}$$

where $p \in \mathbf{R}^n$ is a design parameter, $\Phi_i(p)$ is a real number representing an aspect of the behaviors of the system, and the bound C_i is the maximum tolerable value of $\Phi_i(p)$. Any value of p that satisfies (5) is called a solution of the inequalities (5) and characterizes an acceptable design.

One can solve inequalities (5) either by analytical or numerical method. But, in general, it is necessary and practical to use numerical methods. In this work, an algorithm called the moving boundaries process (MBP) is used to solve inequalities (5). The details of the MBP algorithm can be found in Zakian's original article [5], and also in chapters 1 and 6 of Zakian's recent book [13].

The inequalities (5) include two principal subsets. One is the subset that represents required performance. Whereas constraints have traditionally been represented by inequalities, the representation of desired performance by a set of inequalities is a significant departure from the traditional that requires that performance be represented by a single number $\Phi(p) = \sum_{i=1}^{m} w_i \Phi_i(p)$ (the w_i are weights chosen by the designer), which is to be minimized.

The method of inequalities recognizes that desired performance is appropriately stated by means of several distinct criteria, thus allowling greater insight into the design process.

Over the last thirty years or more, it has been shown that a wide range of practical design problems can be formulated in the form of (5). See [5], [13], [14] and the references therein.

V. AGC CONTROLLER SYSTEM DESIGN

We apply the method of inequalities to the design of a multiarea AGC system. The following assumptions are used in our design formulation.

- We consider only Load Frequency Control (LFC) in the AGC system and discard the coupling effects of automatic voltage regulator.
- Load disturbance, which is demand change, is a step function.
- We consider only small signal dynamic of the system. Therefore, the magnitude of the disturbance is 0.01 p.u.
- We discard the time delay of system.

When a small step disturbance occurs, the AGC system is normally required to fulfil the following objectives.

- Keep frequency deviations $\Delta\omega_i$ equal to zero in steady state.
- Keep the tie-line power flow deviation ΔP_{12} equal to zero in steady state.

According to the concept of tie-line bias control, the area control error in area i (ACE_i) is given by

$$ACE_1 = \Delta P_{12} + B_1 \Delta\omega_1 \tag{6}$$

$$ACE_2 = \Delta P_{21} + B_2 \Delta\omega_2 \tag{7}$$

where B_i is the frequency bias factor in area i. In order that the control system can drive $\Delta\omega_i$ and ΔP_{12} to zero in steady state, it is necessary that the controller employ the integral feedback of ACE_i (see (11) and (13)).

In addition to the above design objectives, we also include some significant electricity market constraints (as described in section III) in the formulation so as to increase the technical and economical reliability of the power system. The details of the design are given below.

A. Design Formulation

Since both areas are identical, it suffices to assume further that only a 0.01 p.u. load disturbance occurs in area 1 (i.e. $\Delta P_{L1} = 0.01$ p.u. and $\Delta P_{L2} = 0$ p.u.). See Figure 1. For the system to have good dynamic responses, it is required that (A) the maximum overshoot (OS), the rise time (T_r) and the settling time (T_s) of the total mechanical power deviation (ΔP_{M1}) are sufficiently small; (B) the maximum values of $|\Delta P_{12}|$, $|\Delta\omega_1|$, $|\Delta\omega_2|$, the total mechanical power deviations of thermal generating unit (IEEEG3 model) in area 1 and 2 ($\Delta P_{MG3,1}$ and $\Delta P_{MG3,2}$) are sufficiently small. The requirement (A) leads to the following design inequalities:

$$\begin{aligned} \Phi_1 &= OS \text{ of } \Delta P_{M1} && \le C_1 \\ \Phi_2 &= T_r \text{ of } \Delta P_{M1} && \le C_2 \\ \Phi_3 &= T_s \text{ of } \Delta P_{M1} && \le C_3 \end{aligned} \tag{8}$$

whereas the requirement (B) leads to

$$\begin{aligned} \Phi_4 &= \max\{|\Delta P_{12}(t)| : t \ge 0\} && \le C_4 \\ \Phi_5 &= \max\{|\Delta\omega_1(t)| : t \ge 0\} && \le C_5 \\ \Phi_6 &= \max\{|\Delta\omega_2(t)| : t \ge 0\} && \le C_6 \\ \Phi_7 &= \max\{\Delta P_{MG3,1}(t) : t \ge 0\} && \le C_7 \\ \Phi_8 &= \max\{\Delta P_{MG3,2}(t) : t \ge 0\} && \le C_8 \end{aligned} \tag{9}$$

In order to increase the system's economical reliability, it is required that (C) the regulation service quality of area 1 (C_{reg1}) and the compliance factor of each area (CF_1 and CF_2) are in the acceptable range described in the market agreement. Since there is no disturbance in area 2, i.e. $C_{reg2} = 0$, we do not consider C_{reg2}. The requirement (C) leads to the following design inequalities.

$$\begin{aligned} \Phi_9 &= C_{reg1} && \le C_9 \\ \Phi_{10} &= CF_1 && \le C_{10} \\ \Phi_{11} &= CF_2 && \le C_{11} \end{aligned} \tag{10}$$

Since the two control areas are identical, the transfer functions of both area controllers (see Figure 1) are chosen to be the same; that is, $G_1(s) = G_2(s)$.

In solving the inequalities given in (8), (9) and (10) for an acceptable design solution, various forms of $G_1(s)$ and $G_2(s)$ are chosen. Usually, it is a common practice to start with $G_1(s)$ and $G_2(s)$ with the least complexity; if a design solution is not found, then a more complex controller structure is used.

B. Numerical Results

First, choose

$$G_1(s) = G_2(s) = \frac{p_1}{s} \tag{11}$$

After a large number of iterations, the MBP cannot locate an acceptable design specified in Table II. An approximate solution can be found by relaxing some design specification in Table II. For example, by letting $C_1 = 0.2$, $C_3 = 41$ sec. and $C_9 = 0.51$, an approximate solution is found.

$$G_1(s) = G_2(s) = \frac{0.10816}{s} \tag{12}$$

where the corresponding values of $\Phi_i(p)$ are given in Table III.

Then, reformulate the design problem by choosing

$$G_1(s) = G_2(s) = \frac{p_1}{s} + p_2 \cdot \left(\frac{s+p_3}{s+p_4}\right) \tag{13}$$

After a number of iterations, the MBP locates a sucessful design given by

$$G_1(s) = G_2(s) = \frac{0.02148}{s} + 0.03997 \cdot \left(\frac{s+1.39888}{s+0.06939}\right) \tag{14}$$

where the corresponding values of $\Phi_i(p)$ are given in Table III and the responses of the system are in Figures 6 and 7.

TABLE II

DESIGN SPECIFICATIONS

$C_1 = 0.1$	$C_2 = 2.5$ sec.	$C_3 = 27$ sec.
$C_4 = 0.0045$ p.u.	$C_5 = 0.0015$ p.u.	$C_6 = 0.0015$ p.u.
$C_7 = 0.0099$ p.u.	$C_8 = 0.0099$ p.u.	$C_9 = 0.3950$
$C_{10} = 6.525 \times 10^{-5}$	$C_{11} = 6.525 \times 10^{-5}$	

TABLE III

DESIGN RESULTS

For AGC with integral controller (12)

$\Phi_1 = 0.19457$	$\Phi_2 = 2.44116$ sec.	$\Phi_3 = 40.7617$ sec.
$\Phi_4 = 0.00450$ p.u.	$\Phi_5 = 0.00125$ p.u.	$\Phi_6 = 0.00076$ p.u.
$\Phi_7 = 0.00923$ p.u.	$\Phi_8 = 0.00289$ p.u.	$\Phi_9 = 0.50881$
$\Phi_{10} = 2.078 \times 10^{-7}$	$\Phi_{11} = 7.254 \times 10^{-9}$	

For AGC with more complex controller (14)

$\Phi_1 = 0.09248$	$\Phi_2 = 2.33385$ sec.	$\Phi_3 = 26.9983$ sec.
$\Phi_4 = 0.00438$ p.u.	$\Phi_5 = 0.00124$ p.u.	$\Phi_6 = 0.00059$ p.u.
$\Phi_7 = 0.00895$ p.u.	$\Phi_8 = 0.00193$ p.u.	$\Phi_9 = 0.39338$
$\Phi_{10} = 5.38 \times 10^{-6}$	$\Phi_{11} = -3.99 \times 10^{-8}$	

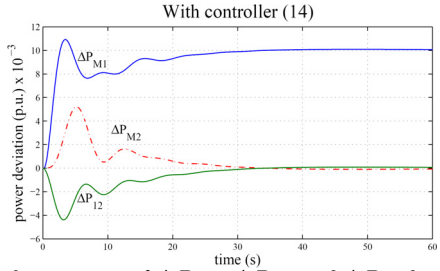

Fig. 6. The responses of ΔP_{M1}, ΔP_{M2} and ΔP_{12} due to ΔP_{L1}.

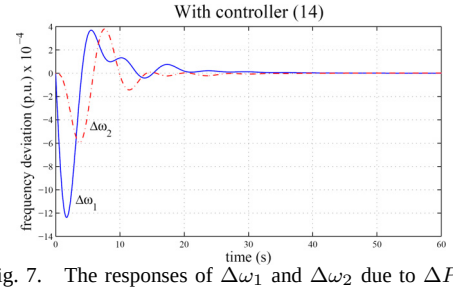

Fig. 7. The responses of $\Delta\omega_1$ and $\Delta\omega_2$ due to ΔP_{L1}.

VI. CONCLUSION

From the numerical results, we can see that the method of inequalities can solve this kind of design problem effectively so that the AGC system can have good dynamic responses and, at the same time, can increase its economical reliability. Furthermore, the advantage of this method is that new design criteria are easily incorporated into the design process in the form of additional inequalities. When the market criteria are changed, it is easy to update the parameters of the AGC controller in order to gain the system reliability. It is worth pointing out here that, by using the method of inequalities, we can choose to design not only the controller parameters but also the parameters in other parts of the power system.

***Abstract*-This paper proposes a method for solving an optimal feeder routing problem. All practical issues, e.g., technical constraints (voltage drop and thermal limits), uncertainty of future demand, and existing infrastructure, etc., are taken into consideration. The proposed method can automatically determine appropriate feeder configuration and does not require prior knowledge of feeder routing candidates. The method integrates planner's experience and optimization process to achieve appropriate practical solutions. Then, the optimal conductor size is selected base on minimum cost with fuzzy cost analysis. The proposed method has been tested with an actual distribution system, from which the results indicate that it can provide satisfactory plans.**

I. INTRODUCTION

Distribution system planning basically involves the optimization of both location and size of a new substation and feeders to meet the requirement of an expected demand while satisfying specified constraints, e.g. substation capacity, feeder thermal capacity, voltage drop, etc.

Optimal distribution system planning is recognized as a very complex problem due to a large number of variables and network configuration candidates, related to the characteristics of the geographical area and the consumer load. Several approaches have been proposed [1-9] to solve distribution system planning problem. Each approach is based on mathematical programming techniques, e.g., linear programming [1, 2], mixed-integer programming [3], non-linear programming [4], dynamic programming [5], quadratic programming [6], and branch and bound algorithm [7, 8]. However, most of the approaches assume that the candidates of feeders routing is known in advance. With this assumption, the problem can be simplified but more appropriate solutions may be neglected.

Since the planning period normally ranges from 5 to 20 years, the demand uncertainty is embedded in the problem. However, in general, intrinsic uncertainty on the future demand is not explicitly considered in solving distribution system planning problems [1-9]. Recently, an extensive application of geographical information systems (GIS), i.e. routes of streets and roads, has enabled the representation of distribution systems in more detail. The distribution planning can be done in a more detailed consideration.

In this paper, a method for the distribution system planning of a radial network of medium voltage (MV) level is presented. To cope with demand uncertainty, a fuzzy number is employed to model the future demand. In addition, heuristic rules by experienced planners will be incorporated to determine feeder path according to actual geographical conditions, e.g. streets, canals, etc., in the planning area. Based on the developed algorithm, the program selects the path and size of conductors, which provide minimum or close to minimum total cost of the system.

II. OPTIMAL FEEDER ROUTING

A. *Objective Function*

The objective of this proposed method is to determine size and configuration of feeders based on the minimum cost. Thus, the problem can be formulated as (1).

$$\text{Min } Cost_{total} = \text{Min } [Cost_{feeder} + Cost_{losses}] \quad (1)$$

where $Cost_{total}$ is the total cost over the planning period,
$Cost_{feeder}$ is the cost of conductor to be installed, and
$Cost_{losses}$ is the cost of expected power loss.

B. *Solving Procedure*

The solving process of the proposed method can be illustrated by the flowchart shown in figure 1.

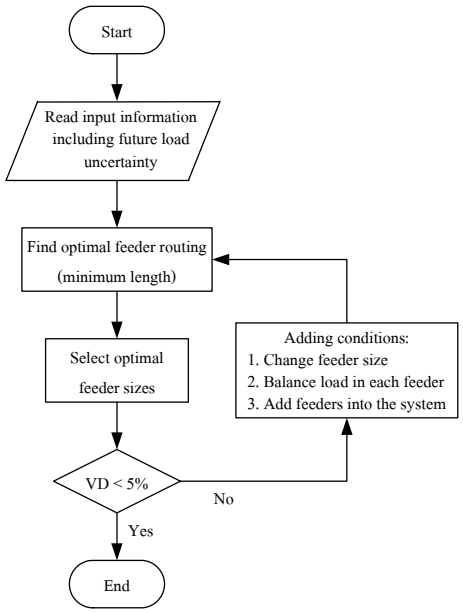

Figure 1. Flowchart of the solving process

This process comprises two solving steps, e.g., determine appropriate routing and select optimal size of feeders.

The process starts from input information, i.e. the location and demand of each load point, the future load growth, and the substation location, etc. Then, feeder routing is determined by the minimum path algorithm with heuristic rules taking into account existing infrastructure, e.g. streets, roads, etc. Then optimal size of the feeder in each branch is selected in the next step.

As a preliminary result, the single-line diagram of the distribution network is obtained, from which system voltage drop is verified. If the voltage drop constraint is violated, a three-step procedure, i.e. 1) adjusting the larger conductor size, 2) balancing load in each feeder, and 3) adding the number of feeder, is applied.

III. FUZZY DEMAND MODEL [10,11]

For considering the demand uncertainty, the fuzzy model is used to represent the future load growth. In this paper, the future load growth is modeled by a triangular fuzzy number, which can be illustrated by figure 2.

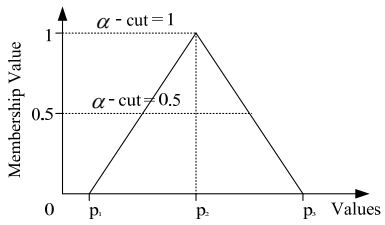

Figure 2. Future load growth model, $\tilde{p} = (p_1, p_2, p_3)$

where p_1 - the minimum plausible load growth value
p_2 - the highest plausible load growth value
p_3 - the maximum plausible load growth value

Base on planner's experiences, the future load growth can be appropriately defined. For example, the planner expected load growth is about 4% but not over 5% and not less than 3%, so the expected load growth can be defined by (3%, 4%, 5%).

This model will be applied with all load points which the load growth value at each load point will depend on the planner's experiences.

IV. THE PROPOSED METHODOLOGY

The proposed method can be divided in two main steps, e.g. determine optimal routing, and select optimal size of feeder. Details of each step can be illustrated below.

A. Optimal Feeder Routing

From the input data, the site and the demand of the medium voltage (MV) substation are known. The objective is to search for an appropriate feeder routing which can save both investment and operation cost subjected to certain constrains.

As the cost of feeder is proportional to its length, the problem may be simplified to minimize feeder length. Minimum path algorithm [9] is used and described below.

The minimum path algorithm:

- Initially, the planner assigns a required number of feeders from the new substation, e.g. two feeders. Then, two sets of nodes are created for each feeder, i.e. connected nodes (A) and unconnected nodes (A′).

A = {substation node}

A′ = {all the load points and road points}

- The distance from any nodes in A′ to the nodes in A is computed and the number of nodes (equal to number of feeders), close to the substation, are removed from set A′ to set A.

- The distance from any nodes in A′ is then compared with the nodes in A. The shortest distance is then sought out. The node with the shortest distance is added to A.

- Repeat above steps until all the load points are in set A and set A′ is an empty set.

In order to present the principles of this step, a system which consists of 130 expected load points as shown in figure 3 is considered, where the geographical information which is presented by ARCVIEW is taken into account. The light line at the back of figure presents the existing road in the study area.

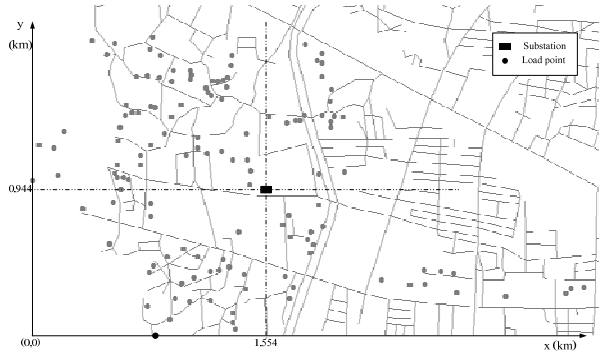

Figure 3. Case study system

Optimal feeder routing will be obtained from this step. If the existing infrastructure is neglected, the main feeder will be connected directly from one load point to another by using the minimum path algorithm.

In case of considering existing infrastructure, we assume that the main feeders should be lined along the existing road. Therefore, the point on the road which is nearest to the defined load point will be considered and use as a candidate for determining the optimal feeder path. The procedure for considering existing road can be described below.

1) The planner firstly defines a maximum allowable length from a load point to an existing road.
2) Distance between a couple of load points and the specified road is considered. If the distance is within the defined value, a lateral line will be connected from that load point to the existing point on the road which is used to be a candidate for determining the main feeder routing.
3) The load points with the distance longer than the defined value will be used to determine the main feeder routing.
4) In case that some load points are connected to very close points on the same road, e.g. within 2 meters, etc.,

they will be set into the same group. In figure 4, there are three load groups.

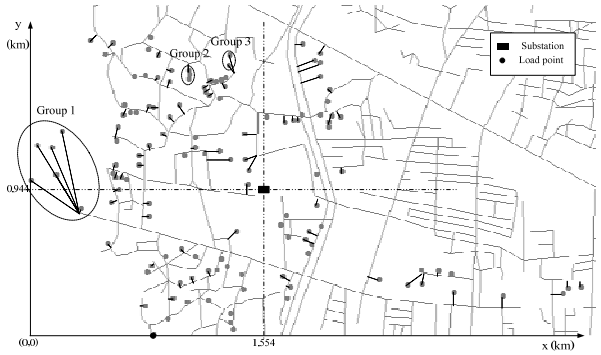

Figure 4. Distance from load points to the nearest road.

5) In each group, all load nodes are connected to each other before being connected to the main feeder using the minimum path algorithm. For example, group1 consists of 6 load points, which are connected to each other using the minimum path algorithm. The result is shown in figure 5. The node which is closest to the specified road is defined as the candidate point of the group.

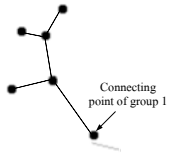

Figure 5. Minimal path in group 1.

In addition each candidate has to strictly comply with the heuristic rules defined below.

Rule 1. If the line has a right of way problem then it is not acceptable.

Rule 2. If the line has high cost passage then it is not acceptable.

Rule 3. If the line pass through an obstacle, i.e. forest, lake, etc., then it is not acceptable.

After using the above process, the optimal feeder routing is determined by using the minimal path algorithm. Then conductor sizes in each branch will be selected as described in the next topic.

B. Selecting Optimal Conductors

Cost function of the conductor is composed of two parts, i.e. *fixed cost* representing capital cost, maintenance and operation (O&M) cost, and *variable cost* representing cost of energy and demand loss. The total cost is obtained by following expression.

$$\tilde{C}_{Total} = C_{fixed} + \tilde{C}_{\text{var}} \cdot L^2 \qquad (2)$$

$$C_{fixed} = \left[\frac{A \cdot i}{[1-(1+i)^{-N}]} + B \right] \times \frac{1}{i}\left[1-(1+i)^{-n}\right] \qquad (3)$$

$$\tilde{C}_{\text{var}} = \left(\frac{8760 \times 10^3 \cdot E \cdot R \cdot L_f}{V^2} \right) \sum_{m=1}^{n} \frac{(1+\tilde{\tau})^{2m}}{(1+i)^m} \qquad (4)$$

where L = Peak Demand flow in conductor (MVA)
A = Investment Cost (Baht)
B = Maintenance & Operation Cost (Baht)
E = Energy Cost of losses (Baht/kWh)
i = Interest rate (%)
L_f = Loss factor, $\left(L_f = 0.3L_d + 0.7L_d^2\right)$
N = Expected life time (years)

An appropriate size of the conductor should be selected in order that the total cost is minimum. Four conductor sizes, of which their details are shown in Table I, are considered.

TABLE I
THE DETAILS OF EACH CONDUCTOR SIZES

Type (mm^2)	Capital Cost (Baths/km)	O & M Cost (Baths/km)	R (Ω/km)	X (Ω/km)
50	102740	1541	0.6895	0.7888
95	131670	1975	0.4005	0.7548
120	168320	2525	0.3158	0.7576
185	241587	3624	0.2250	0.7434

From the cost information in Table I, the fuzzy cost of each conductor size will be obtained by assuming that the loss value of 2 Baht/kWh, 20 years planning period, 30 years life-time, 6% annual interest, and load growth is (4%, 6%, 8%), which is illustrated in figure 6.

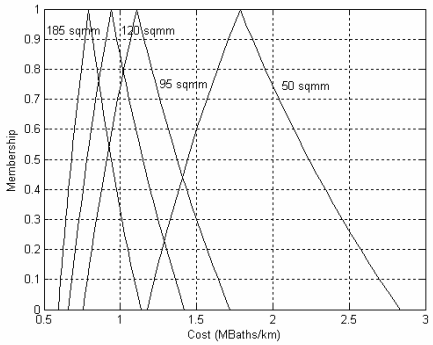

Figure 6. Fuzzy cost of each conductor size at load 2 MW

The fuzzy cost of each conductor size will be compared to find the best option using the center of areas method to convert the fuzzy costs into crisp costs. In figure 6, the 185 sqmm. conductor size is selected because of it provides minimum cost.

Voltage drop is then considered after the above process has been completed. If the voltage drop in the network is within an acceptable limit (5%), the process will be terminated. However, if it violates the limit, one of the following steps must be performed.

- *Adjusting the conductor size*: the conductor in each branch will be adjusted and analyzed.
- *Balancing load in each feeder*: review the load balance in the case of having more than one feeder. If the difference of the aggregated load on each feeder is more than the capacity of lowest load point, the feeder which supplies loads less than other feeders will be forced to connect with more loads, i.e. the nearest load.
- *Adding the number of feeders*: if 1) and 2) have been done and the voltage drop violates the defined limit, the number of feeders should be increased by one more feeder.

This procedure is repeated until the voltage drop is with in the limit.

V. STUDY CASE

The study system is an actual distribution system in Thailand which is shown in figure 3. A 22-kV network is composed of 130 nodes which are divided into two zones. In each zone, a future load growth is differently defined, i.e. (2, 4, 6) % and (1, 3, 5) % respectively. The results of the optimal feeder routing in each case are shown in Table II.

TABLE II
COMPARATIVE RESULTS OF EACH CASE

Case Optimal Routing	Cost of conductor (MBaht)	
	Fuzzy	Expected
I. Ignoring the existing path	(5.268, 6.857, 9.527)	6.946
II. Allowable distance		
- 50 m	(5.625, 7.231, 9.931)	7.322
- 60 m	(5.706, 7.330, 10.059)	7.421
- 70 m	(5.951, 7.660, 10.533)	7.757
- 80 m	(5.880, 7.522, 10.283)	7.615
- 90 m	(5.870, 7.504, 10.251)	7.596
- 100 m	(5.878, 7.511, 10.256)	7.603

From Table II, case I which ignores existing road results in the lowest solution. In case II with the maximum allowable distance from the load point being considered to the existing road of 50 -100 meters is considered. It can be found that the maximum allowable distance of 50 meters provides the lowest cost. The results show that the defined distance does not dictate the conductor cost, however, the geographical characteristics will play an important role in such case.

VI. CONCLUSIONS

The proposed method provides appropriate feeder routing and sizing with consideration of demand uncertainty and existing infrastructure. The future demand uncertainty is considered by representing future load growth with fuzzy model. Moreover the geographic information and heuristic rules are applied in the problem while all technical constraints, i.e., voltage drop, thermal limits are taken into account. This method can be effectively applied in realistic problems, where all the above mentioned constraints are taken into account.

Abstract- **This paper presents the problems of 115 kV and 22kV transmission network of the Central 1 area in Lao PDR under expected load increase forecasted in the years 2005-2013 and optimizes capacitor banks allocations to maximize the net saving cost resulting from power losses and energy losses reduction. The installation of capacitor banks also reduces equipment's overloading in the system. The problems of the system in the future are shortage of reactive power support, under voltage at various buses, increased transmission losses and the tendency of voltage collapse initiation in the industrial area. This paper studies a simulated system of Lao PDR under a load forecasted in 2005-2013 to determine the susceptibility of the system under increased loading and demonstrates the effectiveness of optimization techniques to allocate capacitor banks at certain buses to mitigate the problems at the minimum investment cost.**

Keywords: Power flow, Voltage profile, capacitor bank, losses reduction

I. INTRODUCTION

At present, power systems are steadily growing and become more complex. Interconnection with neighboring system is necessary for power transfer commitment, reliable and economic operation conditions. Under increased loading, power systems are confronted with many problems such as voltage instability, under voltages and high transmission loss. These problems become a major concern in power system planning and operation.

One of the major problems of the system is insufficient reactive power support under increasing load demand, which results in voltage drop at various buses. Addition capacitor banks must be installed at the candidate buses, in the vicinity of large reactive load, to improve the voltage profile of the system and to reduce the risk of voltage instability problem and to lower transmission loss. The problem concerning adding new capacitor banks to improve the system is referred to as "reactive power allocation problem".

Reactors and capacitor banks have long been utilized as a remedy for voltage problems in power system. Large reactive power surplus or deficiency at light or heavy load conditions, and transmission's equipment overloading, can be overcome with the placement of reactors and capacitor banks at appropriate locations in the network.

A system contingency is defined as a potentially harmful for a steady state operation of an electrical network that can result in possible loss of parts in the network.

This paper addresses to optimize capacitor banks placement by seeking suitable locations and sizes of capacitor banks to maximize net savings and to mitigate the N-1 contingency problem in providing enough electric power of sufficient quality to customers for the proposed system using excel solver.

II. THE LAO PDR SYSTEM

The electricity supply system in Lao PDR comprises four isolating networks as shown in Figure 1. The system is quite small. In the Central-I area, the transmission network encounters many problems such as high system losses, low reliability, and excessive voltage drop during heavy load. Moreover, the active power demands of the Electricity Generating Authority of Thailand (EGAT) forces the surplus active power to of the central I to be less than 20 MW while the central-I has only a 25 MVar capacitor banks [1].

Fig. 1. Service areas in Lao PDR

This paper will focus on the problems of the 115 kV and 22kV transmission network of Central I area in Lao PDR under the forecasted loading.

III. Problem Formulation.

The optimal capacitor placement seeks the optimal locations and sizes of capacitor banks to be placed on the system to maximize the net saving cost resulting from reduction in power losses and energy losses at the minimum investment and installation costs. The optimal capacitor placement problem can be expressed mathematically as follows:

Maximize:

$$J = K_P \Delta P_L + K_E \Delta E_L - C_Q \qquad (1)$$

Subjected to:

1. Power flow analysis. (Equality Constraints).

$$P_{ij} = V_i^2 Y_{ij} \cos(\theta_{ij}) - V_i V_j Y_{ij} \cos(\theta_{ij} - \delta_i + \delta_j)$$
$$Q_{ij} = V_i V_j Y_{ij} \sin(\theta_{ij} - \delta_i + \delta_j) - V_i^2 Y_{ij} \sin(\theta_{ij}) - V_i^2 Y_{sh}$$
$$P_{ji} = V_j^2 Y_{ji} \cos(\theta_{ji}) - V_j V_i Y_{ji} \cos(\theta_{ji} - \delta_j + \delta_i)$$
$$Q_{ji} = V_j V_i Y_{ji} \sin(\theta_{ji} - \delta_j + \delta_i) - V_j^2 Y_{ji} \sin(\theta_{ji}) - V_j^2 Y_{sh}$$
$$P_{Li} - P_{Gi} + \sum_{\substack{j=1 \\ j \neq i}}^{n} Pij = 0 \qquad Q_{Li} - Q_{Gi} - Q_{shi} + \sum_{\substack{j=1 \\ j \neq i}}^{n} Qij = 0$$

2. Inequality Constraints.

$$V_{i\min} \le V_i \le V_{i\max} \qquad V_{j\min} \le V_j \le V_{j\max}$$
$$P_{G_{i\min}} \le P_{G_i} \le P_{G_{i\max}} \qquad Q_{G_{i\min}} \le Q_{G_i} \le Q_{G_{i\max}}$$

The expression for objective function contains several conversion factors to saving in dollars e.g. reduction in power loss(K_P), different in power loss due to the addition of capacitors (ΔP_L); the reduction in energy loss to saving in dollars(K_E); the different in energy loss due to the addition of capacitors(ΔE_L); the total cost of the capacitor banks including installation and maintenance costs(C_Q). The difference in total savings minus the total cost of the capacitor banks yields the net savings dollars resulting from the capacitor placement (1).

The energy loss is calculated by using the load duration curve. It is obtained by subtracting the energy loss after the addition of capacitors from the energy loss of the base case. The reduction in energy loss is multiplied by the factor K_E to obtain its contribution to saving dollars. The reduction in energy loss can be expressed mathematically as follows:

$$\Delta E_L = \Delta P_L \times L_S F \times 8760 \text{ , } L_S F = 0.2LF + 0.8LF^2$$

LF = Total annual energy / (Annual peak load × 8760)

L_sF, LF are loss and annual factors respectively.

IV. Capacitor Banks Allocation by Excel Solver

The processes of optimized capacitor banks allocation with excel solver is shown in Figure 2.

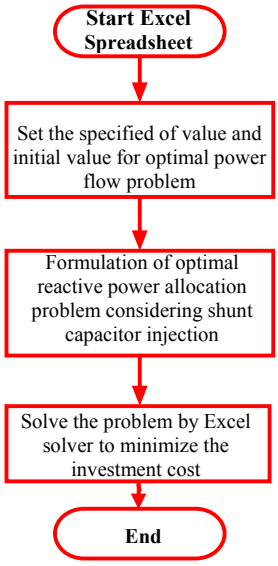

Fig.2. Processes of optimized capacitor bank allocation with excel solver

V. N-1 Contingency Analysis.

The N-1 contingency analysis is a part of reliability assessment of transmission system expansion project. It assesses the ability of the network to provide enough electric power of sufficient quality to connected customers. The process of N-1 contingency analysis using the Excel solver can be illustrated in Figure 3:

Step I. Study the load flow analysis for the existing power system under normal condition

Step II. Analyze the existing power system with increased loading demand requirement following load forecasting results.

Step III. N-1 contingency for all transmission lines in order to find out the weak buses, the transmission losses, and transmission overloading.

Step IV. Solve the problem by indicate weak bus allocate Var source injection and add new transmission's equipment

VI. Results and Discussions.

1. Results of Optimal Capacitors Placement.

The study is carried out on the existing 50-bus ,115/22 kV system of the Central 1 in Lao PDR shown in Figure 4 whose system data are in tables 1,2, and 3. The results of the base case in year 2005 show that the initial MW and MVar losses in the transmission lines are 9.47 MW and 15.58 MVar respectively. The cost of capacitor banks and other associated costs are presented in table 4. The values of the conversion factors K_P and K_E of the objective function were chosen to be $1390/kW per year and $0.031/kWh respectively.

From the simulation results, in case of year 2007 as shown in tables 5 and 6, there are 11 weak buses, three overloading transformers and the system losses is increased from the base case of year 2005. These problems can be improved by additional var sources of 7.5 MVar, 3MVar, 5.5 MVar, 5 MVar, 2.5 MVar and 5MVar at buses 31, 32, 33, 36, 37, 38

respectively and a transformer of 30 MVA must be installed between buses 12(TNL 115kV) and 29(TNL 22kV) to avoid overloading. Similarly, from the year 2008 to 2013 a new var source and transmission's equipment must be installed to improve the voltage profile and avoid transmission's equipment overloading and to reduce transmission losses.

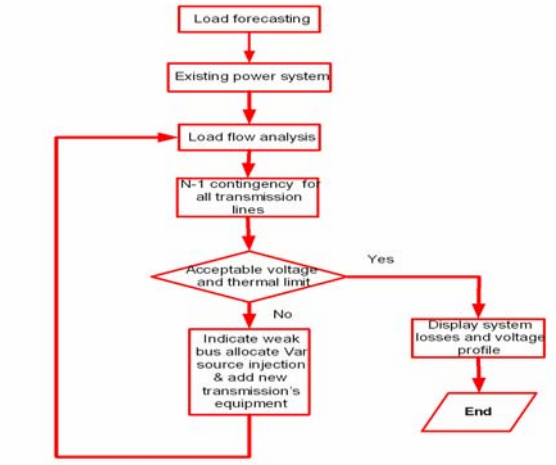

Fig .3. Procedure of N-1 contingency analysis using Excel's solver

2. N-1 CONTINGENCY ANALYSIS.

N-1 contingency analysis is an important task for safe operation of electrical energy network .The study of N-1 contingency will be simulated base on 115kV transmission line in year 2007. If the line between bus 10(PHT 115kV) and 11(NNG1 115kV) is tripped out, there will be 14 weak buses, 3 transformers and 1 line overloading. To evade these problems, new var source of 7.5 Mvar, 7.5 MVar, 5.5 MVar, 5 MVar, 2.5 Mvar, 5 Mvar and 15 Mvar must be installed at buses 31, 32, 33, 36, 37, 38, 43 respectively as illustrated in the table 8.

VI. CONCLUSION

The results of simulation demonstrate that transmission losses, voltage profile and transmission's equipment overloading when load demand increased in the years 2005 - 2013 can be improved by optimize suitable of locations and sizes of capacitor banks to identified weak buses in the Central 1of Lao PDR system in order to maximize the net saving in dollars resulting from reduction in power losses and energy losses, less the investment and installation costs of capacitor banks. In the N-1 contingency analysis, the addition capacitor banks improve the voltage profile of the system. Therefore, transmission equipment's loading can be alleviated.

Voltage Sag Compensation Capability by Parallel Type Compensator with Series Inductor

Sumate Naetiladdanon
Department of Electrical Engineering
King Mongkut's University of Technology Thonburi
126 Pracha Utit Rd. Bangmod, Toongkru, Bangkok 10140 Thailand

***Abstract*- In this paper, the voltage sag compensation capability by parallel type compensator with series inductor is presented. The parallel type compensator injects the current into the system so that the voltage across the series inductor can instantaneously compensate the voltage at the load. The three types of current injection schemes are described and analyzed. The voltage sag compensation capability by parallel type compensator with series inductor is explained and analyzed for each scheme. Simulation results confirmed that voltage sag compensation capability is the function of series inductor and compensator capacity.**

I. INTRODUCTION

Voltage sags are considered as the most dominant and unavoidable power quality problem affecting both utilities and industrial consumers, especially in the term of high costs from lost productivity and downtime. The most effective way to mitigate for voltage sag at the customer level is to apply a voltage sag mitigation equipment at the customer site. Different solutions are currently available for the voltage sag mitigation [1]-[2], where a power electronic converter-based compensator is recognized as an effective mitigating device for its fast compensation capability.

Since voltage sags generally only occur a few times each year at any particular location, a voltage sag compensating device will generally spend most of its time in standby mode. It would be beneficial if the mitigating device can compensate for load as well as voltage sags. The load compensation by the series compensator is not preferable because it will increase the loss for keeping the dc bus voltage constant. The parallel compensator with a static switch can be used for load compensation during normal operation, and compensate a voltage sag during the voltage sag event [3]. However, the compensator must supply load at 100% and the delay from opening the static switch is occurred. The fast voltage sag compensation by parallel type compensator without using the static switch has been presented recently [4]-[6]. The voltage sag compensation is based on injecting the active and reactive power from the parallel type compensator.

This paper shows three different current injection schemes of voltage sag compensation by parallel type compensator with series inductor. The voltage sag compensation capability for these schemes is described. Steady state performances are shown based on simulation results with the various sizes of series inductor and compensator capacity.

II. VOLTAGE SAG COMPENSATION PRINCIPLE

The parallel type compensator with series inductor consists of a voltage source converter (VSC) with an energy storage device in parallel with the load and the inductor in series with the supply voltage, as shown in Fig. 1. A transformer could be used to connect the output of voltage-source converter to the system in parallel. A small capacitor is present on the dc side of the converter where the capacitor voltage is kept constant, by exchanging energy with the energy storage reservoir.

The converter acts as a controllable current source connected in parallel with the load. The parallel compensator can instantaneously compensate voltage sags by regulating the load voltage using the injected current from the converter and the voltage across series inductor bridges the sag. The magnitude of the converter's output ac voltage (i.e. load voltage) is equal to the magnitude of the pre-sag load voltage. The relation of load, line current and injected current can be expressed by

$$\dot{i}_{\mathrm{L}} = \dot{i}_{\mathrm{T}} + \dot{i}_{\mathrm{C}} . \tag{1}$$

And the relation of supply, load and series inductor voltage can be expressed by

$$\dot{v}_{\mathrm{T}} = \dot{v}_{\mathrm{L}} + \dot{v}_{\mathrm{LS}} . \tag{2}$$

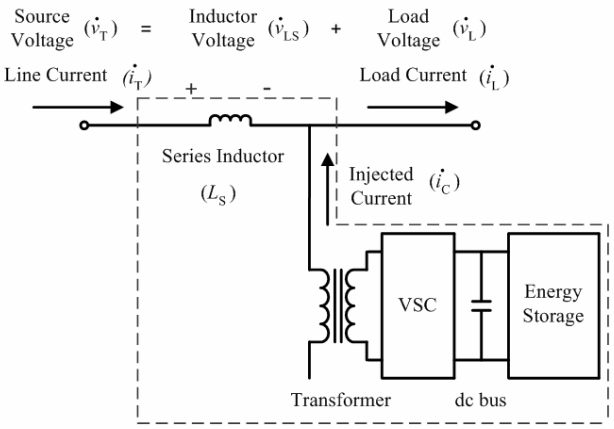

Figure 1. Parallel type compensator with series inductor.

III. CURRENT INJECTION SCHEMES

There are three current injection schemes for voltage sag compensation with different purposes as follows.

A. Phase-invariant current injection scheme

The purpose of this scheme is to protect load voltage from both magnitude and phase disturbances of the supply. The output voltage from the compensator, which is the voltage across the load, will be the same as the pre-sag load voltage ($\dot{V}_{\mathrm{L-pre}}$). The injected current ($\dot{I}_{\mathrm{C}}$) equals to the difference of the load current ($\dot{I}_{\mathrm{L}}$), which equals the pre-sag load current ($\dot{I}_{\mathrm{L-pre}}$), and the during-sag supply current ($\dot{I}_{\mathrm{T}}$) and it can be derived as

$$\left.\begin{aligned} \dot{I}_{\mathrm{L}} &= \dot{I}_{\mathrm{L-pre}} \\ \dot{I}_{\mathrm{C}} &= \dot{I}_{\mathrm{L}} - \dot{I}_{\mathrm{T}} = \dot{I}_{\mathrm{L}} - \frac{\dot{V}_{\mathrm{T}} - \dot{V}_{\mathrm{L}}}{j\omega L_{\mathrm{S}}} \end{aligned}\right\} \tag{3}$$

or

$$I_{\mathrm{C}} e^{j\alpha} = I_{\mathrm{L}} e^{j\varphi} - I_{\mathrm{T}} e^{j\beta} = I_{\mathrm{L}} e^{j\varphi} - \frac{V_{\mathrm{T}} e^{j\theta} - V_{\mathrm{L}} e^{j0}}{\omega L_{\mathrm{S}} e^{j\pi/2}} \tag{4}$$

where φ is the load power factor angle, β is the line current phase angle, α is the injected current phase angle, and θ is the source voltage phase angle by using the pre-sag load voltage as a reference ($\dot{V}_{\mathrm{L}} = \dot{V}_{\mathrm{L-pre}} = V_{\mathrm{L}} e^{j0}$). Fig. 2 illustrates the phasor diagram of the phase-invariant current injection scheme.

B. Minimum energy current injection scheme

The purpose of this scheme is to minimize active power supplied to the load by the compensator. From phase-invariant injection scheme, the injected active power can be expressed by

$$P_{\mathrm{C}} = 3V_{\mathrm{L}}\left(I_{\mathrm{L}}\cos\varphi - I_{\mathrm{T}}\cos(\beta-\gamma)\right) = 3V_{\mathrm{L}}\left(I_{\mathrm{L}}\cos\varphi - \frac{V_{\mathrm{T}}}{\omega L_{\mathrm{S}}}\sin(\theta-\gamma)\right) \tag{5}$$

where γ is the phase angle of the load voltage command, which equals zero in phase-invariant scheme. Note that the sign of γ is negative, if γ is measured by clockwise direction as shown in Fig. 3. The minimum injected active power can be achieved if the difference of θ and γ equals $\pi/2$. However, this could result as the active power absorption from the system in the case of $I_{\mathrm{L}}\cos\varphi \le V_{\mathrm{T}}/(\omega L_{\mathrm{S}})$. Thus, the condition of minimum active power injection can be accomplished by setting γ in (5) to the following angle γ_1 as

$$\gamma_1 = \begin{cases} \theta - \dfrac{\pi}{2} & \text{, when } I_{\mathrm{L}}\cos\varphi > \dfrac{V_{\mathrm{T}}}{\omega L_{\mathrm{S}}} \\ \theta - \sin^{-1}\left(\dfrac{I_{\mathrm{L}}\cos(\varphi)\times\omega L_{\mathrm{S}}}{V_{\mathrm{T}}}\right) & \text{, when } I_{\mathrm{L}}\cos\varphi \le \dfrac{V_{\mathrm{T}}}{\omega L_{\mathrm{S}}} \end{cases} . \tag{6}$$

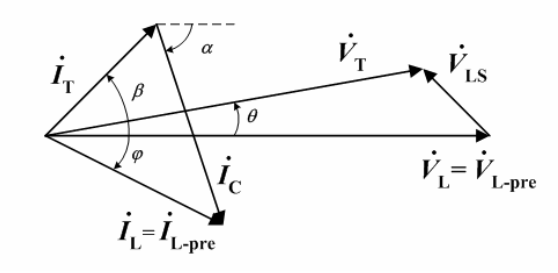

Figure 2. Phasor diagram of phase-invariant injection scheme.

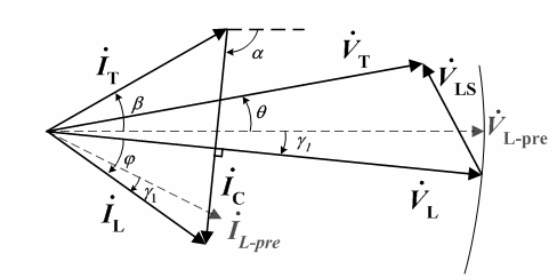

Figure 3. Phasor diagram of minimum energy injection scheme.

Fig. 3 illustrates the phasor diagram of the minimum energy current injection scheme. In a specific case where $I_{\mathrm{L}}\cos\varphi \le V_{\mathrm{T}}/(\omega L_{\mathrm{S}})$, the injected active power can be reduced to zero by setting the injected current phasor to be perpendicular with the load voltage phasor. Because the incoming line must supply active power to the load as much as possible, the incoming line current magnitude will be increased by using this scheme. Instant change of injected current from this scheme might cause the sudden phase angle shift or discontinuity of the load current and voltage during the start-up of injection.

C. Minimum apparent power current injection scheme

The purpose of this scheme is to minimize apparent power supplied to the load by the compensator (i.e. to minimize the compensator's rating). The injected current magnitude can be solved by (3), and the condition of minimum apparent power injection is shown in (7).

$$\frac{\partial I_{\mathrm{C}}}{\partial \gamma} = 0 . \tag{7}$$

Solving equation (7) yields the angle γ as γ_2 which equals by

$$\gamma_2 = \tan^{-1}\left(\frac{Z_{\mathrm{L}}\sin\theta + \omega L_{\mathrm{S}}(\sin\theta\sin\varphi - \cos\theta\cos\varphi)}{Z_{\mathrm{L}}\cos\theta + \omega L_{\mathrm{S}}(\cos\theta\sin\varphi + \sin\theta\cos\varphi)}\right) \tag{8}$$

where Z_{L} is the magnitude of the load impedance. Fig. 4 illustrates the phasor diagram of the minimum apparent power current injection scheme. Instant change of injected current from this scheme might also cause the sudden phase angle shift or discontinuity of the load current and voltage during the start-up of injection.

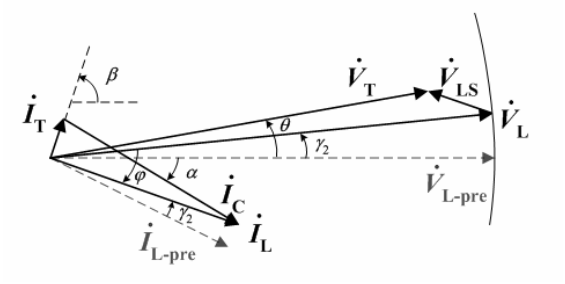

Figure 4. Phasor diagram of minimum apparent power injection scheme

IV. VOLTAGE SAG COMPENSATION CAPABILITY

During the voltage sag compensation, the voltage across series inductor bridges the sag voltage and it can be expressed by

$$\dot{V}_{LS} = j\omega L_S \times \left(\frac{P_T - jQ_T}{\dot{V}_L} \right) = -\frac{\omega L_S Q_T}{\dot{V}_L} - j\frac{\omega L_S P_T}{\dot{V}_L} \tag{9}$$

where P_T is the incoming line active power and Q_T is the incoming line reactive power. The relation of the load, incoming line and injected active power and reactive power can be expressed by

$$\left.\begin{aligned} P_L &= P_T + P_C \\ Q_L &= Q_T + Q_C \end{aligned}\right\}. \tag{10}$$

If $\dot{V}_L = V$+j0 is taken as the reference phasor, the magnitude of the supply voltage during voltage sag compensation can be expressed by

$$\dot{V}_{LS} = j\omega L_S \times \left(\frac{P_T - jQ_T}{\dot{V}_L} \right) = -\frac{\omega L_S Q_T}{\dot{V}_L} - j\frac{\omega L_S P_T}{\dot{V}_L}. \tag{11}$$

If Z_L is the magnitude of load impedance, then $V = Z_L$ x I_L where I_L is the load current magnitude. The supply voltage magnitude during voltage sag compensation can be rewritten as

$$V_T = \sqrt{\left[V - \frac{\omega L_S}{Z_L} \times \frac{Q_T}{S_L} \times V \right]^2 + \left[\frac{\omega L_S}{Z_L} \times \frac{P_T}{S_L} \times V \right]^2} \tag{12}$$

or

$$v = \sqrt{[1 - x \times q]^2 + [x \times p]^2} \tag{13}$$

where S_L is the load apparent power, v is the ratio of incoming line voltage magnitude with the load voltage magnitude, x is the ratio of series inductor's reactance with the load impedance, q is the ratio of incoming line reactive power with the load apparent power and p is the ratio of incoming line active power with the load apparent power. By controlling the incoming line active and reactive power through the injected active and reactive power of the compensator, the compensator can have various current injection schemes to compensate the same voltage sag. Thus, the voltage sag compensation capability of the system is the function of the size of series inductor and the capacity of compensator. Although the large series inductor increases the voltage sag compensation, it causes a poor power factor and voltage drop problem during the normal operation. The power availability at load is also reduced due to the increase of the line impedance as well. The voltage sag compensation capability due to the capacity of compensator can be described according to the current injection schemes as follows.

A. Phase-invariant current injection scheme

The injected active power has been expressed by (5) and the injected reactive power from the converter can be expressed by (14) implying that the voltage sag compensation capability is inversely proportional to the source voltage phase angle θ.

$$Q_C = 3V_L \left(I_L \sin\varphi + \frac{V_L - V_T \cos\theta}{\omega L_S} \right) \tag{14}$$

B. Minimum energy current injection scheme

In a specific case where $I_L \cos\varphi \le V_T/(\omega L_S)$, the injected active power can be zero (P_C = 0). The voltage sag compensation capability in (13) can be rewritten as (15) implying that the voltage sag compensation capability is proportional to the compensator capacity.

$$v = \sqrt{[1 - x \times q]^2 + [x \times \cos\varphi]^2} \tag{15}$$

C. Minimum apparent power current injection scheme

As the compensator capacity can be minimized, the voltage sag compensation capability is maximized by this injection scheme. The condition of maximum voltage compensation is shown in (16). Solving (16) yields the required reactive power and voltage sag compensation capability as shown in (17) and (18) where s_C is the ratio of compensator capacity with the load capacity.

$$\frac{\partial v}{\partial q} = 0 \tag{16}$$

$$q = \frac{s_c}{\sqrt{1 + x^2}} \tag{17}$$

$$v = \sqrt{[1 - xq]^2 + \left[x\left(\cos\varphi - \sqrt{s_C^2 - (\sin\varphi - q)^2} \right) \right]^2} \tag{18}$$

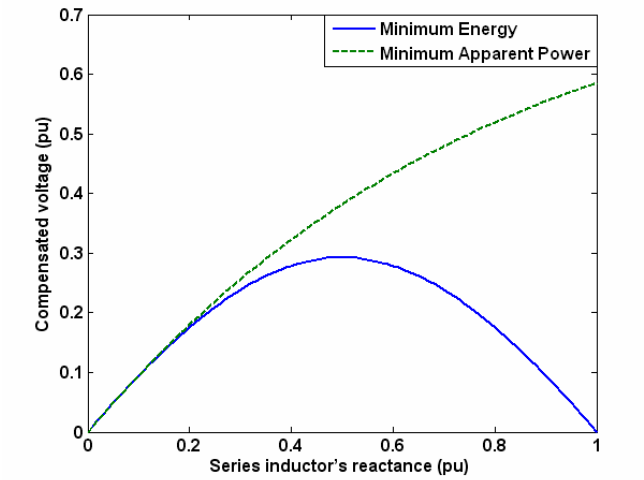

Figure 4. Compensation capability as function of series inductor.

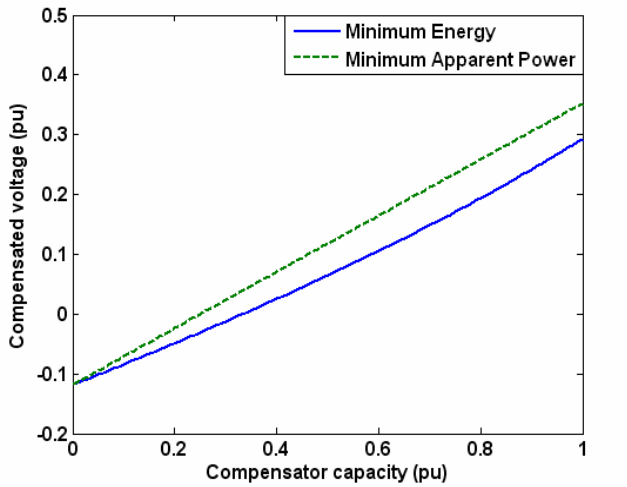

Figure 5. Compensation capability as function of compensator capacity.

V. Simulation Results

The system in Fig. 1 is used to demonstrate the steady state performance of voltage sag compensation capability. It is considered that the pre-sag load voltage magnitude is 1.0 pu and the system load is 1.0 pu with unity power factor, then the incoming line reactive power is the result of the compensator's injected reactive power. Note that the phase-invariant current injection scheme is not considered due to the variation of source voltage phase angle θ.

A. With Fixed Compensator Capacity

The capacity of compensator is considered to be the same as the load capacity, that is S_C = 1.0 pu. The voltage sag compensation capability as the function of series inductor size is shown in Fig. 4 for the minimum energy and minimum apparent power injection scheme. Using the minimum apparent power injection scheme, the compensated voltage can be increased as the series inductor size increases. For the minimum energy injection scheme, the compensated voltage reached its maximum at the series inductor's reactance = 0.5 pu. The reason of that is the injected current phasor must be perpendicular with the load voltage and it is required more reactive power as the series inductor increases beyond the maximum point.

B. With Fixed Series Inductor Size

The series inductor's reactance is considered to be half of the load impedance, that is x = 0.5 pu. The voltage sag compensation capability as the function of compensator capacity is shown in Fig. 5 for the minimum energy and minimum apparent power injection scheme. Using both injection schemes, the compensated voltage can be increased as the compensator capacity increases where the minimum apparent power scheme give a better compensation performance. The negative compensated voltage occurred at the small compensator capacity because the size of series inductor is too big for the compensation.

VI. Conclusion

The steady state performance of the parallel type compensator with a series inductor has been studied in this paper. The voltage sag compensation is based on injecting reactive power in order to regulate the load voltage, and consequently the voltage across series inductor compensates the sag voltage. Three current injection schemes for different purposes are discussed. Simulation results indicated that the voltage sag compensation capability is determined by the size of series inductor, compensator capacity and current injection scheme as well.

***Abstract*- In this research, we present the study on the application of nanoporous silicon for optoelectronic device which called nanoporous silicon visible light photodetector in this paper. This device was fabricated on nanoporous silicon layer which was formed by electrochemical etching of silicon wafer in hydrofluoric acid solution under various anodization condition such as the resistivity of silicon wafer, current density, concentration of hydrofluoric acid solution and anodization time. The experiment will study on photoresponse and responsetime of nanoporous silicon visible light photodetector which was fabricated on various porosity of nanoporous silicon layer, the photoresponse of device will expand toward the short-wavelength and bandwidth of spectum response will cover visible light. In addition, it is found that responsetime of device increases.**

I. INTRODUCTION

Nanoporous silicon is not a new material. It was observed the first time about its photoluminescence by Canham in 1990 [1]. Although first porous silicon layer had been observed by Ulrich in 1956 [2] and later by Turner but only Canham report about room temperature luminescence beginning significant interest in this material [3]. Later, more detail studies of this film were done by researcher around the world. Because lower cost of a product, possibility of improved performance and optical properties caused that the investigations of luminescence and electrical properties have been made in many laboratories. After the first few years, not only multicolour photoluminescence, but also visible electroluminescence had been reported. Today, the focus of the research has been reported to formatiom, structure and many application of nanoporous silicon such as photovoltaic devices, and light emitting diodes. In this paper, we present results on the study of nanoporous silicon for visible light photodetector.

II. MATERIAL AND METHODS

The nanoporous silicon layer were formed by electrochemical etching of p-type silicon wafers with a resistivity of 10 Ω-cm in hydrofluoric acid solution concentration of 48% for etch times of 20 min which will show in Fig.1. Between anodization using a constant anodic current density of 10, 20 and 40 mA/cm^2. After the electrochemical attack, the samples were rinsed in de-ionized water and blown dry with nitrogen gas. Next step, porosity measurement of nanoporous silicon layer with gravimetric method [4] which calculated using (1) and show in Fig.2.

$$\text{Porosity } \% = \frac{m_1 - m_2}{m_1 - m_3} x100 \qquad (1)$$

Figure 3. (a) Schematic and (b) picture of nanoporous silicon visible light photodetector.

Then devices were reverse-biased voltage and illuminated with a 150w halogen lamp for photoresponse measurement at various wavelength in a rang 400-1200 nm by monochomator. Show in Fig.4.

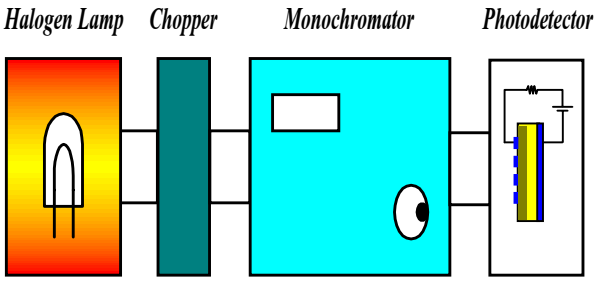

Figure 4. Cross section schematic of silicon wefer in porosity measurement of nanoporous silicon layer with gravimetric method.

After measurement photoresponse, devices were illuminated with red light input from laser diode (LD) at frequency 100 kHz for responsetime measurement of nanoporous silicon photodetector.

III. RESULTS AND DISCUSSION

From the results of porosity measurement of nanoporous silicon layer with gravimetric method. It is found that increasing anodic current density of 10, 20 and 40 mA/cm^2 between anodization have effect to increasing porosity of nanoporous silicon layer with 65%, 70% and 85%, which will show in Fig.5. and Fig.6. respectively.

Figure 6. Top view of nanoporous silicon were formed by electrochemical etching under anodic current density of (a) 10 mA/cm^2 (b) 20 mA/cm^2 and (c) 40 mA/cm^2 respectively.

And from the results of photoresponse measurement of nanoporous silicon photodetector were reverse-biased voltage and illuminated with a 150w halogen lamp at various wavelength in a rang 400-1200 nm by monochomator which will shown in Fig.7.

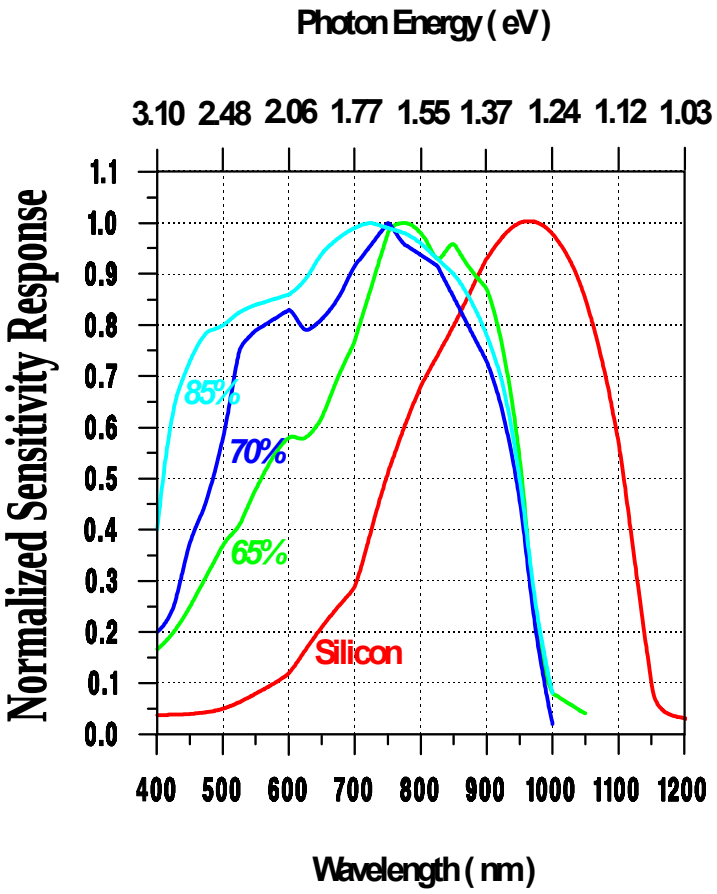

Figure 7. Photoresponse of nanoporous silicon photodetector which was fabricated on nanoporous silicon layer with 65%, 70% and 85% porosity at various wavelength compare with silicon photodiode

It is found that when devices fabricated on higher porosity nanoporous silicon layer, the photoresponse of device will expand toward the short-wavelength and bandwidth of spectrum will cover visible light in a rang 500 to 625 nm. The explanation of this effect, when structure of nanoscale porous silicon decreases which occurs from increasing porosity of nanoporous silicon, the band gab of nanoporous silicon has increase owing to the quantum size effect [5].

From the results of responsetime measurement of nanoporous silicon photodetector which was fabricated on nanoporous silicon layer with 65%, 70% and 85% porosity and it was illuminated with red light input from laser diode (LD) at frequency 100 kHz will show in Fig.8. It is found that when devices fabricated on higher porosity nanoporous silicon layer, the response time of device increases with 2.0 μs, 1.4 μs and 0.8 μs, respectively. This results occurs from increasing of electrical field in space-charge region between Al Schottky contacts and nanoporous silicon layer.

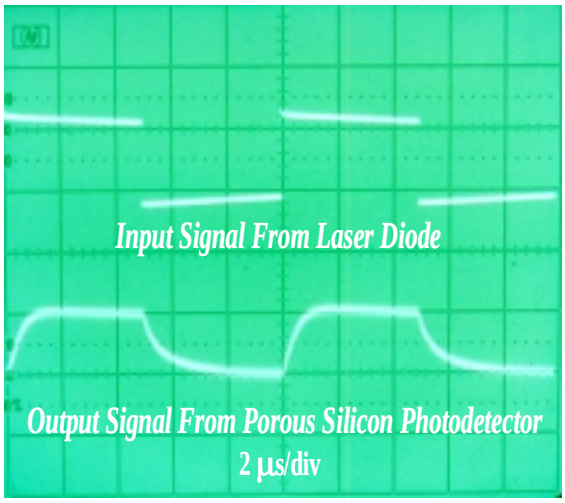
(b)



(c)

Figure 8. Responsetime of nanoporous silicon photodetector at fabricated on porous silicon layer with (a) 65% porosity (b) 70% porosity and (c) 85% porosity.

IV. CONCLUSIONS

In this research, we found that the nanoporous silicon layer can fabricate to optoelectronic device such as the nanoporous silicon visible light photodetector. From the results of experiment, the nanoporous silicon photodetector can response to visible light and have bandwidth spectrum cover in a rang 500 to 625 nm. Different with general silicon photodetector that reponse to infrared wavelength. This results occurs from effect of quantum size effect. And it is found that when nanoporous silicon visible light photodetector was fabricated on higher porosity nanoporous silicon layer, the responsetime of device will increases.

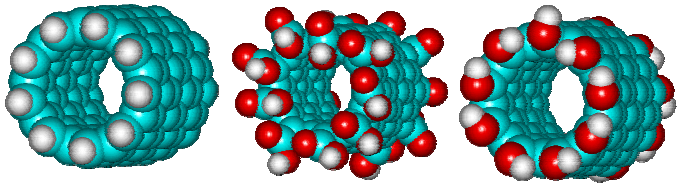
***Abstract*-In this paper, we have investigated various properties of tubule-end functionalized carbon nanotubes using various computational modeling and simulation techniques. Geometrical and electronic properties of chemically modified carbon nanotubes were studied using semi-empirical method based on AM1 Hamiltonian. The movement of water molecule into the center of model tubes was investigated using first principles density functional theory (DFT) calculation and molecular dynamics (MD) simulation. Hydrogen atom (-H), hydroxyl (-OH) and carboxyl (-COOH) functional groups are chemically adsorbed at the open-end of the nanotubes. The results show that the average C-C bond lengths of all tubes are similar about 1.42 Å and the three model tubes exhibit characteristic of semiconducting material. The movement of water molecule into the tip-modified tubes is easier than that of the pristine tube. The tip-modification can improve hydrophilic behavior of pristine and does not alter electronic and mechanical properties of the carbon nanotube. These findings are in agreement with previous experimental works.**

I. INTRODUCTION

Carbon nanotubes (CNT) were first discovered in 1991 by Iijima [1]. After that discovery, research on CNT reaches a critical mass in many areas of physics and chemistry. Because of its remarkable electronic and mechanical properties, CNT is one of the best candidate materials for use in various industrial applications [2]. However, some properties of the pristine tubes limit their use in many applications. For examples, the pristine tube is not soluble in water or common solvent [3] which hinders chemical approaches and preparation of nanocomposite materials. To overcome this obstacle, several research groups try to add surfactants or hydrophilic groups (i.e., hydroxyl (OH), carboxyl (COOH) and aliphatic amines) to the open ends of the tubes [4,5]. After tip-modification these nanotubes are able to disperse in the common solvents as well. However, the geometrical and electronic properties of the CNT and behavior of tubes in water after tip-modification are yet clearly understood due to difficulty in obtaining experimental data at atomic level. Therefore, computational molecular modeling and simulation approaches have emerged as important tools that can be used to predict atomic structure, geometrical and electronic properties, binding energies, tubes-water interactions, etc. In this paper, we employed quantum mechanics (QM) calculations and molecular dynamics (MD) simulation to study the electronic and structural properties, and the movement of water molecule into the model tubes. The built systems for this study are investigated elaborately and systematically.

II. METHODOLOGY

In this study, we consider the single-walled (9,0) carbon nanotubes with chemically modified edges. The ends of the tubes are capped with hydrogen atoms (-H), hydroxyl (-OH) and carboxyl (-COOH) functional groups, respectively, as shown in Fig. 1. Diameter of the tubes is about 7.0 Å. First of all, we investigate the electronic and structural properties of each tube using semi-empirical quantum calculations based on AM1 Hamiltonian [6] and DFT calculations [7] based on 6-31G* basis set. The AM1 method is good enough for the geometry optimization of the nanotubes [8] and B3LYP/6-31G* level was found to be much more reliable for electronic structures [9].



(a) (b) (c)

Figure 1. Geometrical structures of (a) H-SWNT (b) OH-SWNT and (C) COOH-SWNT after optimization by AM1 method

From Fig. 1, these model SWNTs were simulated in the aqueous solution using molecular dynamics technique for studying the water-tubes interaction. The simulations of the model systems have been performed at the constant volume and temperature in a rectangular box containing one SWNT and 871 water molecules. The SWNT is represented by a flexible model based on OPLS force field [10] as well as the SPC water model [11]. The SWNT-water and water-water interactions are represented by a sum of the Lennard-Jones and Coulomb potentials

$$V_{LJ}(r_{ij}) = 4\varepsilon_{ij}\left(\left[\frac{\sigma_{ij}}{r_{ij}}\right]^{12} - \left[\frac{\sigma_{ij}}{r_{ij}}\right]^{6}\right) + \frac{q_i q_j}{r_{ij}} \quad (1)$$

Here, ε and σ are Lennard-Jones parameters, and q_i and q_j represent the charges on atom i and atom j, respectively.

In addition, the results obtained from the MD simulation were verified with the results obtained from ab initio self-consistent field (SCF) calculation also.

III. Results and Discussions

The structural and electronic properties of three different kinds of tip-modified carbon nanotubes are summarized in Table 1. From the Table 1, it indicates that the average C-C bond lengths of all tubes are nearly the same and close to the C-C bond length in the perfect nanotube with sp^2 hybridization (1.42 Å). It means that adsorption of molecules at the tips of the tube does not bring about any structural distortion of the tube whereas adsorption of molecules at the sidewall of tube strongly affect the structure of tube [12], ~1.52 Å of C-C bond length. For electronic properties, energy gaps of the tubes were calculated by using the highest occupied molecular orbital (HOMO) and the lowest unoccupied molecular orbital (LUMO).

$$E_{gap} = LUMO - HOMO \quad (2)$$

The COOH-SWNT has the smallest energy gap while the H-SWNT has the highest one. Such functional groups affect weakly on the energy gap. They help increase an electrical conductivity of the pristine tube. However, if we assume that the energy gap obtained from HOMO and LUMO calculations is equivalent to the band gap concept in solid-state physics, these results would suggest that the SWNTs (9,0) with finite size, which may have or have no modification at the tip of tubes, are small-gap semiconducting tube in which it will become metallic and have no energy gap when the length is long enough [13].

TABLE I
THE AVERAGE C-C BOND-LENGTHS AS OBTAIND FROM GEOMETRY OPTIMIZATION USING AM1 METHOD AND ENERGY GAP OF H-,OH- AND COOH-SWNTS AS CALCULATED FROM B3LYP/6-31G*

System	C-C (Å)	E_{gap}(eV)
H-SWNT	1.417	1.133
OH-SWNT	1.424	1.082
COOH-SWNT	1.424	0.823

After studying fundamental properties of model tubes using QM calculation, the tubes are simulated in water environment containing in the periodic boundary of rectangular box. From this simulation, we calculate radial distribution function (RDF), $g_{x-y}(r)$ and coordination numbers, $n_{x-y}(r)$, from O of the water to center of mass (COM) of tubes, as shown in Fig. 2. The RDF plot of both OH- and COOH-SWNTs is rather similar. It shows one sharp peak of each tube, positioned at 1.89 Å of OH-SWNT and 1.83 Å of COOH-SWNT whereas the RDF plot of H-SWNT does not appear the sharp peak. It indicates that water molecules move close to the center of the tip-modified tube more than the pristine tube. The functionalized groups may ease the entering of water into the hydrophobic tube's interior, in agreement with previous experimental works [4,5].

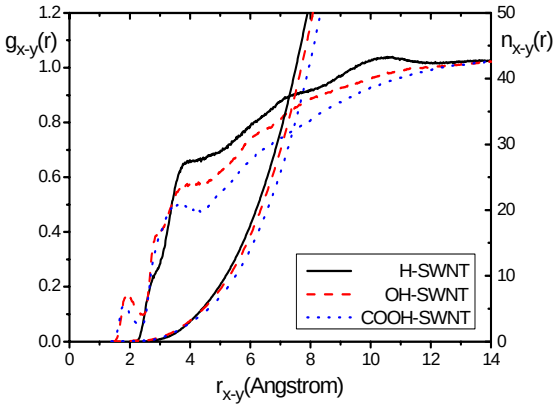


Figure 2. The radial distribution functions, $g_{x-y}(r)$, and corresponding running integration numbers, $n_{x-y}(r)$, from O of the water to COM of H-SWNT, OH-SWNT and COOH-SWNT

To confirm the MD simulation result, interaction between a water molecule and each model tube is calculated by using B3LYP/6-31g* method. For an illustration, the definition of trajectory for a tube interacting with a water molecule is presented in Figure 3. The oxygen atom of a water molecule is moved along the tube axis z, and the hydrogen atoms are symmetrically placed giving the water molecule a fixed orientation.

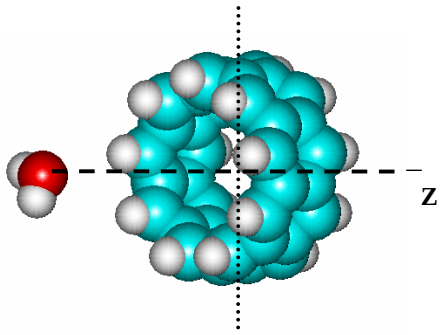

Figure 3. Definition of trajectory for SWNT interacting with a water molecule of fixed orientation at various positions along the tube axis.

In order to evaluate the interactions between these model tubes and the water molecule, the interaction energies are evaluated via (3)

$$E_{int} = E(X\text{-}SWNT/water) - E(X\text{-}SWNT) - E(water) \quad (3)$$

Where E(X-SWNT/water) is the total energy for the model SWNTs plus water molecule (where X= H, OH and COOH), E(X-SWNT) is the total energy of the model tubes and

E(water) is the total energy of the water molecule. In all the analyzed systems, the starting molecules are optimized by using AM1 Method.

Figure 4 shows the interaction energies varying the distances from the O of water molecule to the centers of mass of model tubes. One can be observed that the H-SWNT has a high potential barrier in the range of 2-4 Å from the center of tube and beyond 2 Å, the potential energy barrier is decreasing. It means that water molecule will not move into the center of the tube because the potential barrier height occurs at the tip of tube. In other word, if a water molecule occupy in a tube, it can not go out from the tube's interior. For OH-SWNT, the potential barrier decreases when the water molecule move close to COM of the tube while it experiences a deep potential well when entering the COOH-SWNT from the right side in the given. It indicates that water molecule may enter into the OH-SWNT easier than the COOH-SWNT and the water molecule tend to occupy the position ~ 2-3 Å from COM of COOH-SWNT. The results are in good agreement with the RDF analysis obtained MD simulation above.

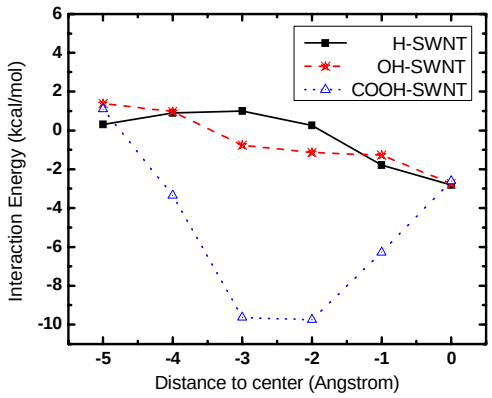

Figure 4. Potential energy surface for the SWNTs interacting with a water molecule of fixed orienta-tion at various positions along the z-tube axis

IV. Conclusions

We have studied the structural and electronic properties in atomically level of chemically modified SWNTs (OH-SWNT and COOH-SWNT) and the pristine SWNT (H-SWNT). Semi-empirical quantum mechanics based on AM1 Hamiltonian and density functional theory (DFT) calculations are employed for such investigations. After modification at the tips of tubes, the C-C bond lengths of all tubes are not different and electrical conductivity of tube increases a little bit. All three model tubes show semiconducting characteristic. For simulations of model tubes in water, the results indicate that water molecules are preferable to move close to the COM of the tip-modified tubes in comparing with the pristine tube. After modification, the water molecules can occupy the hydrophobic tube's interior corresponding to results obtained from the quantum mechanic calculation.

***Abstract*-The electronic and energetic properties of topological defect of single-walled carbon nanotube junctions (SWCNTJ) have been investigated based on the semi-empirical AM1 Hamiltonian calculation. The geometries of junctions occur at the interface between two zigzag tubes having different helicities and diameters. One segment of the fused nanotube is kept constant by using the (5,0) nanotube, while varying another segment from (6,0) to (10,0). Practically, the junctions are constructed by insertion of pentagon-heptagon pair as a defect into the perfect hexagonal lattice. The study shows that junction geometries of SWCNT are dependent on the variation of diameter and length of carbon nanotubes. The HOMO and LUMO levels exhibited the contradiction of even-odd "quantum size" oscillation of nanotube chiralities, although tubule length increased. The occurrence of decreasing energy gap depends on the relationship between tubes index and their length. The energy of formation linearly changes with the variation in nanotubes diameter but not with the tubule length. The (5,0)//(10,0) SWCNTJ have more stability than other SWCNTJ. The outcome of this study would be of help for collection of information in the field of molecular electronic devices made of carbon nanotubes.**

I. INTRODUCTION

At present, carbon nanotubes [1] are one of the most fascinating materials in the field of nanodevices. The experimental observations have shown that the defects structures are possibly form on the hexagonal network structure of carbon nanotubes [2]. These defects can be typically classified into three groups: topological (introduction of ring types other than hexagons), rehybridization (ability of carbon atom to hybridize between sp^2 and sp^3), and incomplete bonding defects (vacancies, dislocations, etc.).

Two nanotubes fused by topological defect group results in tubular junction having different electronic properties [3] that can be useful for construction of various molecular electronic devices. It was predicted theoretically that two carbon nanotubes with different diameter and helicities can be connected by insertion of a pentagon and heptagon rings on the hexagonal lattice of carbon nanotubes [4,5]. The junction nanotubes can be of two types, i.e. positive curvature and negative curvature, thus depending on the pentagon and heptagon on the sidewall of SWCNTs. Therefore, a single walled carbon nanotube (SWCNT) can be either metallic or semiconducting, depending on its chirality and diameter [6].

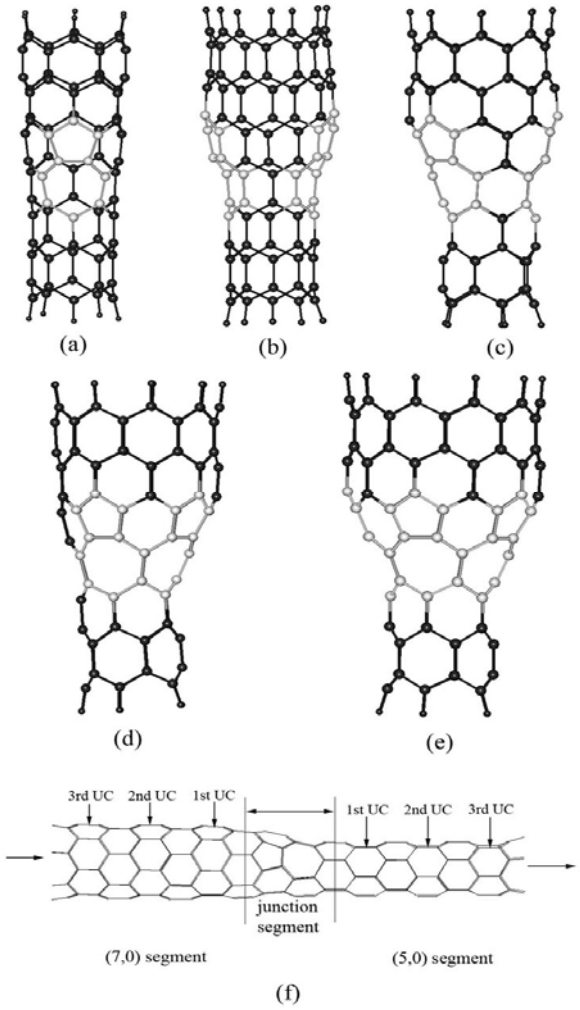

Figure 1. The SWCNTJ models represent the fusing two single walled carbon nanotubes, (a) (5,0)//(6,0) 1UC, (b) (5,0)//(7,0) 1UC, (c) (5,0)//(8,0) 1UC, (d) (5,0)//(9,0) 1UC, and (e) (5,0)//(10,0) 1UC. The variation of tubule length is represent in (f)

Hence, the combination of two segments of SWCNT having different diameters and helicities will lead to different electronic properties of nanotube junction.

In this work, the single-walled carbon nanotube junctions (SWCNTJ) were constructed by fusing two nanotube segments having different diameters (i.e. zigzag (5,0)//(*m*,0)). The different junction geometries of two different diameter SWCNTs are modeled to study the change in electronic structure depending on the variation of tubes diameter and their length by using semi-empirical quantum mechanical calculation. The energies of formation are also investigated the stability of SWCNTJ.

II. Computational Procedures

Two carbon nanotubes with different chiralities and diameters can be fused by inserting a pentagon-heptagon (5/7) pair defect. Different combination of (5/7) pair defects result in different types of junction. In this work, single-walled carbon nanotube junctions (SWCNTJ) are constructed by joining two zigzag (5,0)/(*m*,0) nanotube segments; where *m* is an integer and varies from 6 to 10 (see Fig.1). In this case, the (5,0) segment is kept constant. Creation of various junction structures can be done by inserting various numbers of a (5/7) pair defects into a perfect cylindrical hexagonal lattice around the circumference of SWCNTs. The SWCNTJ of a pentagon and heptagon (5-7) point defect is considered [7]. The junction geometry has constructed by using the "ConTub" web based software [8,9].

The geometries of all SWCNT structure are initially optimized by molecular mechanics (MM3) method. These structures have been used as basis geometries for further optimization by higher-level techniques. The optimized geometries, energetics, and electronic structure of the entire structural variables were obtained from semi-empirical AM1-RHF method. The formation energy of the SWCNTJ is defined as $H_n = -E_{(SWCNTJ)} + E_{(5,0)} + E_{(m,0)} + E_{junction}$, where $E_{(SWCNTJ)}$ is the total energy of SWCNTJ, $E_{(5,0)}$ and $E_{(m,0)}$ are the total energy of each nanotubes segment, and $E_{junction}$ is total energy of junction segment (mean topological (5/7) pair defects structure) and the SWCNT, respectively. All computations were performed by using GAMESS package [10].

III. Results and Discussion

A. Electronic Properties

In the study, the electronic structure versus two parameters, i.e. tube diameter and length, was considered. The HOMO-LUMO energy level was plotted with respect to the varying diameter of (m,0) segments as well as the tube length is increased (see Fig. 2). There is the changing of the numbers of a (5/7) pair defects around the tube circumference. In the diameter variation, it was found that the HOMO and LUMO levels exhibit the contradictory even-odd "quantum size" oscillation, even though the tubule length is increased. For instance, the (5,0)//(7,0) and (5,0)//(9,0) junctions have lower HOMO-LUMO energy than the (5,0)//(6,0), (5,0)//(8,0) and (5,0)//(10,0) pairs. These effects would be useful for design of electronic devices. This is the primary information that should be taken into account when nanoscale devices that made from SWCNTJ are to be constructed. In Fig. 3, the energy gap demonstrates that both tubule diameter and length parameters

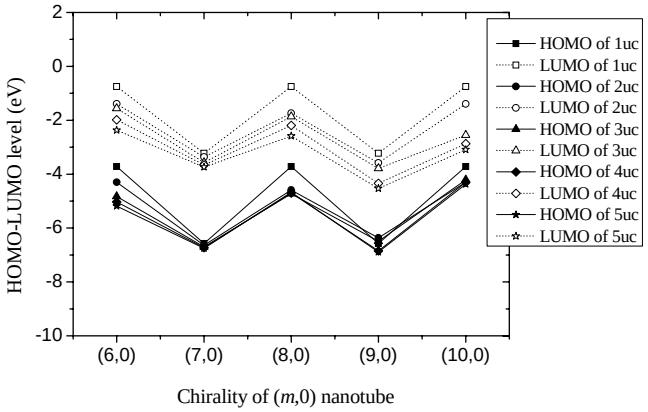

Figure 2. Demonstration of HOMO-LUMO energy levels versus the variation of zigzag nanotube indices.

contribute to the difference in energy gap of SWCNTJ. For instances, the consideration of diameter changed with respect to 1UC (see Fig. 1), it does not show any change in energy gaps. In contrast, the increasing tubule length has a consequence of decreasing energy gap for all tube indices. Especially, the (5,0)//(10,0) junction shows the energy gap decreasing from 2.9 eV to 1.3 eV of 1UC to 5UC, respectively. For other SWCNTJs, even if the tubule length is increased to 5UC, the energy gap is still larger than the (5,0)//(10,0) junction.

The energy gap respects to increasing numbers of unit cell (UC) was plotted in Fig. 4. It exhibits that the energy gap of the (5,0)//(10,0) junction at 5UC is less than the other configurations in conjuction with Fig 3. It must be noted that our prediction is rather rough because the semi-empirical AM1 RHF technique neglects the repulsive interactions and overestimates the frontier energy gap. However, the geometrical parameters obtained from such low-cost method can be transferred to further studies using more accurate methods. Consequently, these results would assist in checking

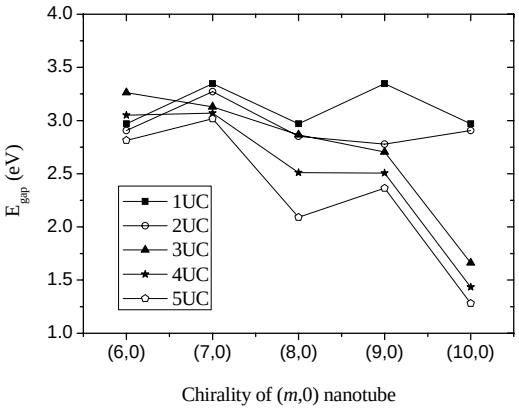

Figure 3. The energy gap (E_{gap}) of SWCNTJ plotted versus tube indices as well as tubule length.

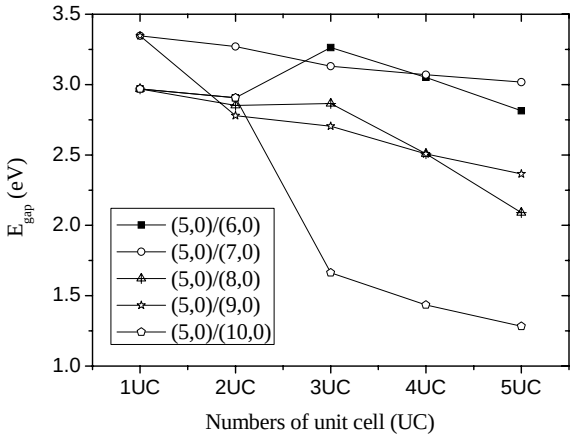

Figure 4. The energy gap (E_{gap}) of various SWCNTJ plotted respect to tubule length.

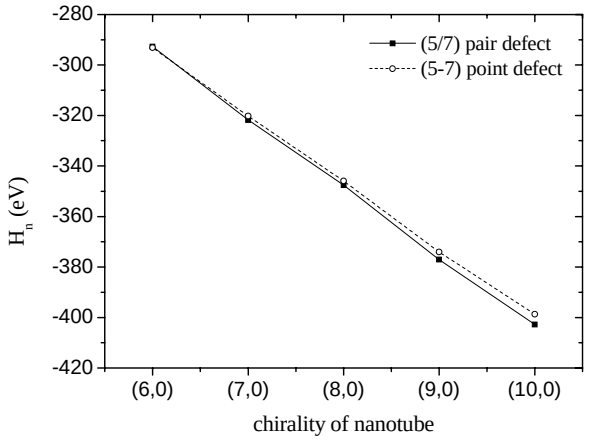

Figure 6. The energy of formation (H_n) of two types SWCNTJ 3UC respects to chiralities of nanotube.

the possibility of making moletronic devices, e.g. molecular rectifier, from the SWCNTJ structures.

B. Formation of SWCNTJ

The energy of formation of our (5/7) pair defect of SWCNTJ structures were plotted in comparison with a (5-7) point defect of SWCNTJ as shown in Fig. 6. A (5-7) point defect junction is shown in Fig 5. It is composed of separated pentagon and heptagon rings on the hexagonal network of

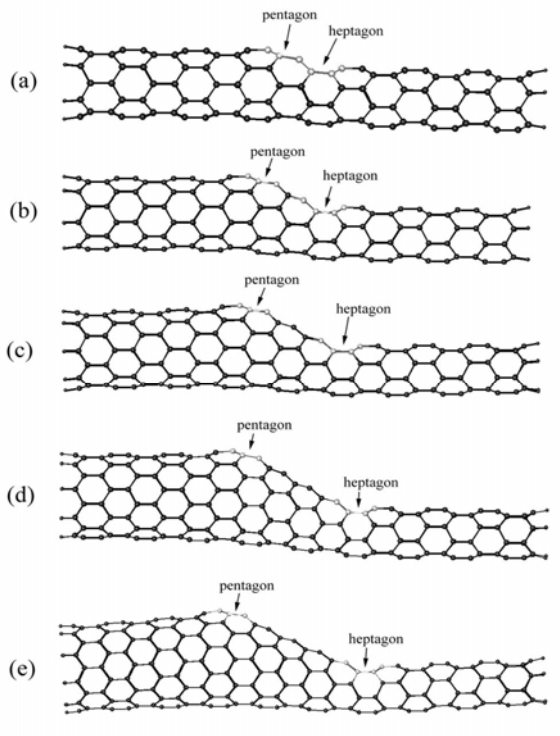

Figure 5. The representation of a (5-7) point defects of SWCNTJ 3UC structures. The models follow (a) (5,0)//(6,0), (b) (5,0)//(7,0), (c) (5,0)//(8,0), (d) (5,0)//(9,0), and (e) (5,0)//(10,0), respectively.

SWCNT that also make two nanotube segments to be connected. The pristine SWCNT of structures follow the same indices of a (5/7) pair defect of 3UC SWCNTJ structures.

The energy of formation as a function of the tube's chiralities reveal that the (5,0)//(10,0) structure is more stable than other ones. The energy of formation for both pair defect and point defect junctions are almost the same, for instances, the pair defect and point defect (5,0)//(10,0) junctions have the energy of formation of 402 eV and 398 eV, respectively. From the variations of tube diameter, i.e. (6, 0) (or ~ 4.75 Å) to (10, 0) (or ~7.92 Å), the energy of formation is decreasing linearly as the diameters of SWCNT are increasing. However, the energy of formation as a function of tubule length is not linearly dependent on the tubule length.

IV. Conclusion

In summary, the results from AM1-RHF calculations have shown that the electronic structure, i.e. HOMO-LUMO energy and energy gap, depends on variation of diameter and length of carbon nanotubes. The HOMO and LUMO levels exhibited the contradiction of even-odd "quantum size" oscillation of nanotube chiralities, although the tubule length is increased. The energy gap that implies metallic or semi-conducting behavior depends on correlation between the tubes indices and tubule length. The energy of formation linearly changes with the variation of nanotubes diameter but not with the tubule length. The (5,0)//(10,0) SWCNTJ have more stable than other SWCNTJ. The outcome of this study would be of help for collection of information in the field of molecular electronic devices made of carbon nanotubes.

***Abstract*-Optical profiling on lateral spreading of space-charge-region properties of Schottky-barrier metal-semiconductor-metal (MSM) structures have been investigated experimentally. Making use of a planar molybdenum/n-type silicon /molybdenum (Mo/n-Si/Mo) MSM structure with a wide electrode separation, one-dimensional (1D) profiling of optical–beam intensity distribution from a helium-neon (He-Ne) laser was carried out. It was also confirmed that, in addition to existing photosensing function, the sensitivity (output photocurrent) of such a structure could be controlled by an applying bias via lateral spreading of the surface space-charge-region (SCR) at the side of the Schottky-junction reverse-biased.**

I. INTRODUCTION

The blocking (Schottky-barrier) metal-semiconductor-metal (MSM) structure is a viable and fundamental device structure in the field of light-wave communication and optical data processing systems. This structure provides several advantages such as wide-band operation, low-noise behaviour [1], ease of integration with other functions on the same chip and so forth [2].

Recently we experimentally confirmed that a planar MSM structure having a wide separation between the two metal electrodes exhibits not only the function of a basic optical sensor but also optical sensitivity field-controllable by the bias applied between the electrodes [4]. In this study, we present the experimental results of one-dimensional (1D) optical-beam profiling properties of an MSM structure as its application[2,3]. To our knowledge, no study has appeared on such an application of planar MSM structures.

II. MODEL OF OPERATION

The essential cross-section of the structure we treat in this study is illustrated schematically in Fig.1. The structure is of single-slit type (not interdigitated), the bird's eye view of which is also inset in Fig.1. Schottky-barrier is formed at each boundary between the metal and the semiconductor. The separation between the electrodes located at both ends is wide enough to leave the undepleted neutral region under the bias we examined. When a bias voltage is applied between the electrodes, one Schottky-junction is reverse-biased and the other junction is forward-biased.

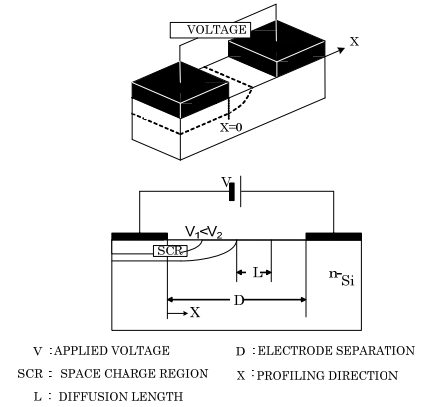

Figure 1. Schematic illustration of an MSM structure, leaving an undepleted region even under a bias.

Such a structure is expected to show lateral spreading of its space-charge-region (SCR) at the Schottky-barrier reverse-biased, the spreading of which is possible to be controlled by bias. According to the simplified model of such a structure, the width of the lateral spreading of the SCR of the Schottky-junction reverse-biased in the direction of profiling is expressed semi-empirically as[4]

$$W(V_a) = \sqrt{\beta(V_0 + V_a)} \qquad (1)$$

where $W(V_a)$ is the width of lateral spreading of the SCR along the surface of the active area at an applied bias V_a, $\beta = 2\varepsilon_s / qN_D$, ε_S is the permittivity of the semiconductor employed, q is the elementary charge, N_D is the impurity concentration and V_0 is the built-in voltage of the Schottky-barrier, respectively. The barrier on the other side is forward-biased and assumed to be nearly flattened for simplicity, although the residual undepleted region might exhibit an appreciable resistance reflecting its wide length. Therefore, when the influence of this resistance is taken into account, the applied bias V_a might be replaced by V_a-IR in (1), where I is the device average current and R is the equivalent series resistance. Thus, the photoinduced current $I_P(V_a)$ is approximately formulated as [4]:

$$I_p(V_a) = \eta[kW(V_a) + L] \qquad (2)$$

where L is the diffusion length of the semiconductor and k means that the SCR is k-times more effective to generate the photocurrent than the residual undepleted region (presumably, larger than unity, and η is the proportionality factor including the effect of quantum efficiency and intensity level of irradiation. As a result, $I_P(V_a)$ is would be an increasing function of applying bias V_a with the dependence on $\sqrt{V_0 + V_a}$ This means that the device structure under consideration is to furnish the field-controllable iris, although the equivalent size as a pixel also increases in the direction of profiling with the bias applied.

III. EXPERIMENTAL

A. Sample description

To make the electrodes of $3\times3\ \mathrm{mm}^2$, molybdenum film working also as barrier metal was deposited onto an n-type silicon wafer by an electron-beam evaporator and was subsequently processed by photolithography lift-off technique. The electrode separation is mainly 2000 μm. The resistivity of the wafer used was $(40\text{-}50)\,\Omega\mathrm{cm}$. This resistivity would provide corresponding donor concentration of some $3\times10^{16}\mathrm{cm}^{-3}$. The height of the Schottky-barrier on both sides was estimated to be $(0.55\text{-}0.65)\,eV$ from the forward current–voltage characteristic[5]. Furthermore, from this value of the barrier-height, the built-in voltage V_0 is deduced to be approximately $0.23\,eV$

B. Optical profiling procedure

Here we examine profiling of the light-beam from a He-Ne laser, the wave length of which is 633nm. The experimental system for profiling was arranged to suppress the influence of the stray light including reflected light from the ambient surfaces of the sample under test. The orientation of the incident light from the light source was tilted a little from the normal line of the active area of the device in the plane perpendicular to the profiling direction. The optical beam was scanned by every 15 μm in the perpendicular orientation of the tilting plane of the beam. Correspondingly, the influence of the tilt of the beam is presumably minimized in 1D direction where we are intending to profile. Spatial intensity distribution of the beam to be detected was assumed to be Gaussian distribution with the radius (2σ) of 480 μm defined at the point of $1/e^2$ its maximum just at the aperture of the light source quoted by the manufacturer [6]. The dispersion angle of the beam from the source is approximately $0.23\,mrad$. To control the light intensity incident onto the sample, a neutral density (ND) filter was utilized. Furthermore, since the electrode separation is wide, no interference of incident light is assumed at the very edge of each electrode.

IV. RESULT AND DISCUSSION

A. 1D-profiling properties

We observed the spatial distribution of detected photocurrent over the whole region between the electrodes, the typical plot of which is shown in Fig. 2.

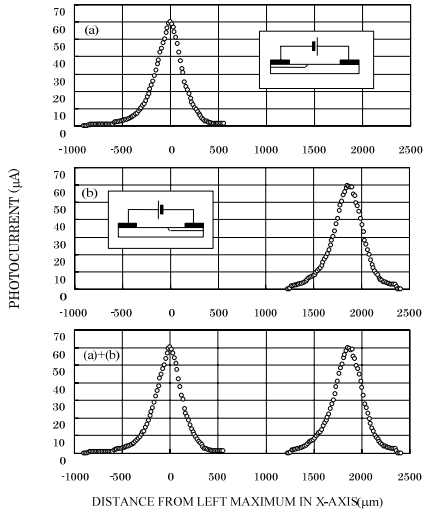

Figure. 2. Spatial distribution of the photocurrent under a constant optical illumination level versus the lateral position of every 15 μm step. Electrode separation is 2000 μm.

The photocurrent was obtained by subtracting the dark current from the current as measured at the same bias. Each peak in the Fig.2(a) and (b) corresponds to the profile when the polarity of applied bias is reversed. From the Fig. (a)+(b), the separation of the two peaks is estimated to be about 1920 μm, which is a little smaller than the electrode separation.

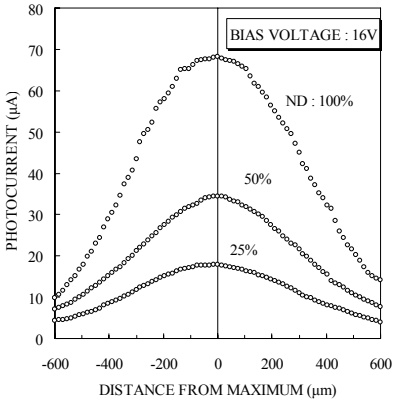

Figure.3. Photocurrent distribution under three different intensities of illumination at $V_a = 16\mathrm{V}$ for the same sample appeared in Fig.2.

It is apparent from these Figures that only the SCR of the junction reverse-biased generates significant photocurrent. On the contrary, the current from the barrier forward-biased on the other side is extremely small and is substantially ignored. Therefore, these two similar peaks must correspond to the photocurrent dominantly from the SCR of respective junction reverse-biased, showing k is larger than unity. Therefore, these results suggest that the region where no detectable photocurrent is observed can be treated to have substantially flat band.

Figure 3 shows the photocurrent versus position relationship for the sample appeared in Fig. 2 under a bias of 16V at the distance of 10cm from the aperture of the light source, taking the intensity of the illumination as a parameter. Here the light intensity was controlled by an ND filter between 25 per cent and 100 per cent of its maximum. One finds that the level of each peak corresponds to the optical intensity level.

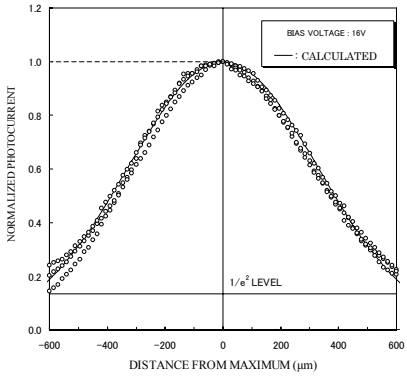

Figure.4. Normalized plot of the spatial current distribution from the data in Fig.3. Solid line represents the calculated Gaussian distribution for reference, taking $2\sigma = 480\mu m$.

Furthermore, the normalized plots from the data in Fig.3 are shown in Fig.4, where the solid line represents the Gaussian curve calculated from the parameters given by the manufacturer of the light source. A good agreement has been obtained between the experimental plots for different illumination levels and the plot theoretically expected. We also performed the profiling at the several different distances from the light source ranging from 10cm to 60cm. The plots given in Fig. 5 are the ones showing the detected current distribution of the beam versus the distance from each maximum.

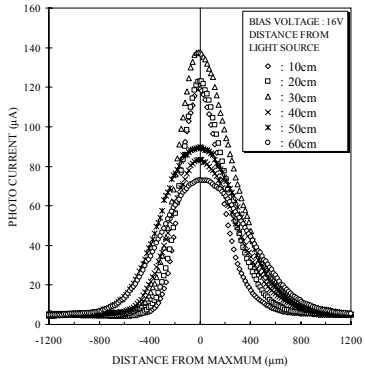

Figure.5. 2σ dependence of the spatial distribution of current on the distance from the light source.

From the data in Fig. 5, halves of normalized curves are replotted in Fig. 6, where the solid lines correspond to the lines calculated respectively. It is found that a good agreement has also been achieved between the experimental and calculated plots. In Fig. 7 is shown the radii of the optical beam experimentally obtained and numerically expected with respect to the distance from the light source for the case $V_a = 16V$. With increasing the distance, the difference between these two plots seems to decrease.

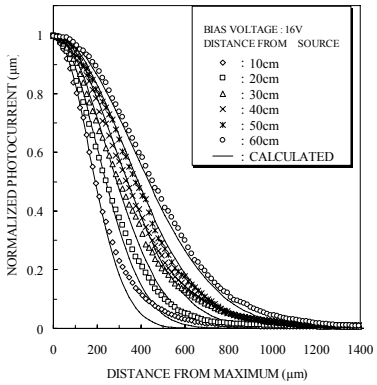

Figure.6. Normalized profiles of currents with respect to the distance from the maximum, where solid lines were calculated, respectively.

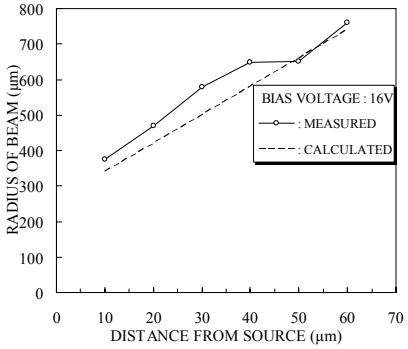

Figure.7. Experimental and calculated radii of the beam versus distance from light source.

This is curious a little. Generally, an increase in the difference between the two plots is expected with increasing the distance from the source.

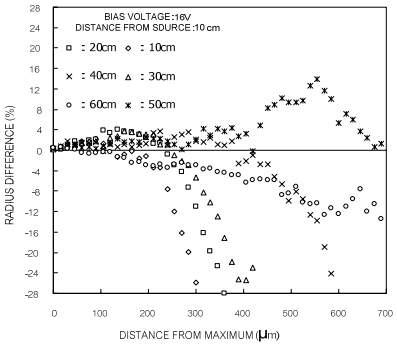

Figure. 8. Dependence of the difference in radii between experimentally observed and calculated on distance from the maximum.

In order to clarify this result further, we plotted in Fig. 8 the dependence of the difference in per cent between the experimental and calculated plots on the distance from the intensity maximum point, where the distance from the source was taken as a parameter. On the contrary, the difference seems to increase more or less with the distance from its maximum. These results observed might be attributed to incompleteness of avoiding the influence of stray light on the measured photocurrents. That is, with increase in the distance from the source, the influence of stray light on the profiling decreases.

B. Field-controllability of profiling

We also carried out profiling by changing the bias voltage. Fig. 9 pictures the experimental plots for V_a=2V, 4V and 16V biases. In Fig.10, the plots normalized at the peak value are shown, where the solid line corresponds the level theoretically expected. Again, a good agreement has been obtained from the view point of the level predicted, while the beam size being substantially unchanged even under the change in the bias applied. As a result, it can be concluded that the planar MSM structure examined can be used as a simple intensity profiler of an optical-beam of this size.

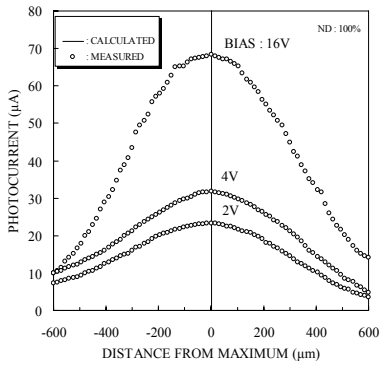

Figure.9. Bias dependence of experimental spatial intensity distribution for $Va = 2V, 4V$ and 16V.

However, it should be in mind that the detected spatial distribution of the current is for the photocurrent essentially given by (2). Therefore, with the increase in bias, the width of the SCR also increases following (1), which means the increase in size of the pixel. We used, in the present experiments, the silicon wafer of the resistivity of (40-50) Ωcm for preparing samples. This resistivity expects the change in the width of the SCR, $W(V_a)$, from 6 μm to 16 μm at most between 2V and 16V. As mentioned earlier, the profiling was carried out changing the relative position by every 15 μm step, which is still larger or approximately equal comparing to the width of the SCR.

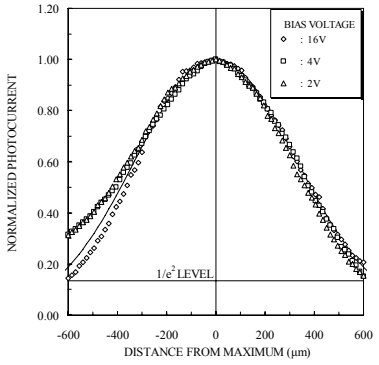

Figure. 10. Profiling normalized at the maximum for the bias V_a=2V,4V and 16V obtained from Fig.9.

Therefore, it can be mentioned that the beam profiling would still be effective. We repeated the similar measurements on the structure having 20 μm electrode separation. In spite that the diffusion length estimated to be 70 μm must be considered in generating photocurrents, no direct evidence of the contribution from the diffusion current was observed. This result might be attributed that the SCR is several times more efficient than the same area within the diffusion length in generating photocurrent [4,5]. Therefore, one can mention that the structure examined in this study is usable as a pixel for 1D optical-beam profiling, having the field-controllable sensitivity. It can also be mentioned that the increase in detected photocurrent is explained by the reflection of the photoexcited current due to the carriers laterally accumulated by spreading of the SCR with an applied bias. It is of interest that the effect of an optical spot position on the performance of MSM structures with no applied bias has been investigated previously [5]. This method, however, utilizes solely the current generation via photoexcitation of carriers like a solar cell. Therefore, the operation mechanism of this structure is essentially different from that of the structure we proposed in the present study.

V. CONCLUSION

As a novel application, a planar MSM (metal-semiconductor-metal) structure has been applied to profiling of the spatial intensity distribution of an optical beam in visible range. The Gaussian intensity distribution of the beam from a He-Ne laser was confirmed experimentally. The MSM structure proposed in this study also exhibits field-controllable sensitivity making use of lateral spreading of the SCR (space-charge-region) at the active surface. The performance of this structure is well explained by the simplified model.

***Abstract*-.This contribution reports the correlation between conditions of film preparation and magnitude of the interchain aggregation of conjugated polymer, poly[2-methoxy,5-(2′-ethylhexoxy)-1,4-phenylenevinylene] (MEH–PPV). It was found that the extent of interchain aggregation in thin films, prepared by spin casting from solutions, depended on solvents and spinning speed. Uv/vis absorption spectroscopy revealed that the use of polymer solutions in xylene resulted in the films with higher aggregate fraction compared to that of the films made from the solutions in 1,2-dichlorobenzene. The results were consistent with the measurements by atomic force microscopy, which suggested a better chain packing in the smoother films made from solutions in xylene. Increasing spinning speed was also found to promote the interchain aggregation, attributed to the stretching of main chain due to the increase of centrifugal force. The MEH-PPV films fabricated by using different conditions were fabricated into plastic solar cell, constituting of the structure Al/MEH-PPV/PSS:PEDOT/ITO/Glass. The properties of the obtained plastic solar cells were compared to explore the relationship between magnitude of interchain aggregation in thin films and the device performance.**

I. INTRODUCTION

The photovoltaic (PV) cells have become increasingly attractive to scientific community due to their potential as a clean alternative energy source. The disadvantage of the crystalline silicon-base PV mainly arises from the relatively high cost of semiconductor manufacturing. On the other hand, the polymer based PV devices provide several advantages [1]. In addition to the low cost of materials and fabrication process, polymer PV cells also exhibit properties such as mechanical flexibility and durability, which are unachievable from the inorganic counter part [2]. However, fundamental understanding about properties of the conjugated polymers used to fabricate the PV cells is essential for the optimization of its performance. The optical and charge transport properties of the conjugated polymers have been known to depend significantly on conformation of individual chain and the molecular packing in solid state . The extended chain conformation and interchain aggregation of conjugated polymers in thin films promotes charge transport, which in turn is expected to enhance the performance of solar cells [3]. Therefore it is rather important to learn how to control the degree of interchain aggregation in thin films. Since the aggregation requires significant overlapping of multiple conjugated backbones, local chain conformation affects its magnitude significantly [3]. In this study, we explore the relationship between the fabrication processes and degree of interchain aggregation in thin films of the well-known conjugated polymer, poly[2-methoxy, 5-(2′-ethylhexoxy)-1,4-phenylenevinylene] (MEH–PPV). Several studies have demonstrated that the conformation of MEH-PPV varies significantly with local polymer-solvent interactions [3,10]. Therefore, one may utilize this knowledge to adjust the MEH-PPV chains to be in the desired conformation. The films prepared from solutions using different solvents are expected to contain different fraction of aggregates. Since the fabrication process of the PV devices normally uses the spin casting technique to prepare polymeric thin films, the spinning of substrate which unavoidably applies centrifugal force to polymeric chains is also expected to play important role. These two processing parameters are investigated in this study. The performances of PV devices constituting of MEH-PPV with different degree of interchain aggregation are compared to explore its role.

II. METHODOLOGY

The MEH-PPV was synthesized according to the procedure described in literature [4]. Fresh solutions were prepared by dissolving powder sample in solvents, 1,2-dichlorobenzene (DCB) and dimethylbenzene (xylene). All solutions appeared homogeneous. The films for atomic force microscopy (AFM) measurements were prepared by dropping solutions (0.01, 0.05, 0.5 mg/ml) on a freshly cleaned silicon wafer. The cleaning of the silicon wafers were performed by soaking in a warm piranha solution (7:3 v/v mixture of conc. H_2SO_4 and 30% H_2O_2) for about 1 h. The substrate was rinsed several times by deionized water and dried by pressurized N_2 gas. All films were allowed to dry in ambient conditions for over night. The morphologies of thin films were explored by using AFM (SPI3800N Nanoscope II, Seiko Instrument Inc., Japan). The films for UV/vis absorption measurements were prepared by spin casting from solutions with concentrations of 10 and 15 mg/mL onto glass substrate. The spinning speeds were varied from 1,000 to 5,000 rpm. The absorption spectra

of each film were recorded using a Jenway 6405 Uv/vis spectrophotometer. The surface morphologies and thicknesses of spin cast films were measured by AFM.

Structure of photovoltaic solar cells in this study consists of Al/MEH-PPV/PSS:PEDOT/ITO. All devices have area of 1.6×2 cm^2. Thickness of ITO, PSS:PEDOT and Al layers are about 140, 35 and 100 nm, respectively. The thickness of MEH-PPV depends on fabrication conditions (see below). The cleaning of ITO coated on glass substrate was performed by subsequent rinsing and sonicating in deionized water and isopropanol. The substrates were dried with nitrogen gas. It is followed by spin coating a thin layer of poly(3,4-ethylenedioxythiopene)(PEDOT):poly(styrenesul fonate) (PSS) to modify the ITO surfaces. Active layers of these devices were prepared by spin casting MEH-PPV solutions (10 or 15 mg/mL) on PSS: PEDOT/ITO with resistance of 30 Ω/c.m. All films were dried by keeping them in a glove box filled with nitrogen gas for overnight. Finally, the aluminum electrode was evaporated on top of the polymeric film. The current voltage (*I-V*) curves were measured with keithley 4200 semiconductor analyzer.

III. Results and Discussion

In first section, the effects of solvent and spinning speed on the magnitude of interchain aggregation in thin films are explored by utilizing UV/vis absorption spectroscopy. Fig. 1, illustrates the absorption spectra of MEH-PPV films prepared by using different solvents and spinning speeds. All spectra exhibit a maximum absorption at about 490-500 nm with broad red-shift shoulder at about 550 nm. It has been shown that the absorbance at 550 nm corresponds to the concentration of aggregated chains, which require significant interchain stacking, while the absorbance at 490-500 nm represents the fraction of non-aggregated one [5]. It is clear that increasing spinning speed is accompanied by the growth of the red-shift shoulder as shown in Fig. 1a Using different solvents to fabricate the films while spinning speed is kept constant also results in different pattern of absorption spectra. Fig. 1b, shows that the use of xylene solvent provides absorption spectrum with relatively stronger red-shift shoulder. The increase of absorbance at about 550 nm corresponds to the higher fraction of aggregates in the films [5]. We can compare the fraction of aggregates in different films by measuring ratio of absorbance at 550/490 nm. Fig. 2, illustrates this absorbance ratio of different films. It is obvious that the films prepared form solutions in xylene consist of larger fraction of aggregates. The increase of spinning speed from 1,000 to 3,000 rpm also causes a systematic increase of aggregate fraction. Further increasing the spinning speed to 4,000 and 5,000 rpm, however, hardly affects the aggregate fraction.

The effects of solvent on the magnitude of aggregation in thin films are attributed to the different of chain conformation in each solvent. The MEH-PPV chain constitutes of phenyl rings, double bonds and alkoxy side chains, making it virtually a non-polar molecule. Therefore, it is expected that it adopts different conformation in xylene and 1,2-dichlorbenzene, a non-polar and polar solvents, respectively. In fact, study by static light scattering indicates that p-xylene is a moderate solvent for MEH-PPV [6]. In other word, the conformation of MEH-PPV in p-xylene is a random coil. The chain is expected to collapse in the more polar solvent, DCB, due to the unfavorable polymer-solvent interactions. The chain in the more open conformation is expected to promote the aggregation in thin films consistent with other studies [3]. The effects of spinning speed are also expected to arise from the change of local chain conformation during the fabrication process. The spinning of substrate means that the centrifugal force is applied to the polymeric chains. The magnitude of this force increases with spinning speed, which stretches the chain to larger extent. The stretched chains can stack more efficiently, resulting in larger fraction of aggregates in the films.

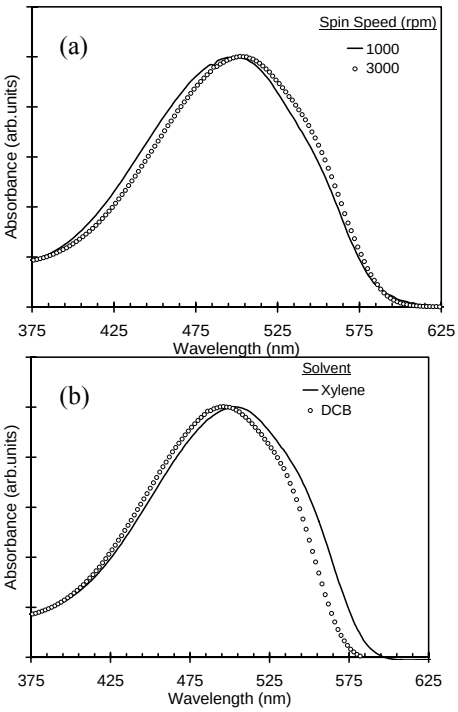

Figure 1. Normalized absorption spectra for MEH-PPV films prepared by using different (a) spin speeds and (b) solvents. The concentration of all solutions was 10 mg/mL. Solvent in (a) is xylene. Spinning speed in (b) is fixed at 4,000 rpm.

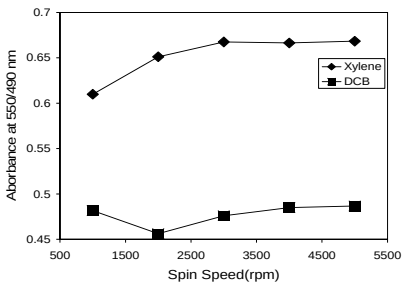

Figure 2. Plot of absorbance at 550 nm relative to 490 nm as a function of spin speed. The films were made from 10 mg/mL MEH-PPV solutions in in DCB and xylene.

The molecular packing of polymers in thin films was further explored by using AFM. The films were prepared by drop casting (i.e. self-assembling) and spin casting. The study of drop cast films provides information of film morphology forming without the perturbation of external forces. Therefore, local polymer-solvents play a major role on the molecular packing into thin film. Fig. 3, illustrates AFM topography images of the MEH-PPV films prepared by the drop casting of 0.05 mg/mL solutions of DCB and xylene. The films obtained by using the two solvents exhibit rather different surface morphologies. Using the solutions of DCB provides rather rough surface with relatively large domains distributing throughout the film. The polymer solution in xylene, on the other hand, yields much smoother film. Study of the films prepared from 0.01 and 0.5 mg/mL solutions provides consistent results. The detection of many polymer droplets in Fig. 3a, corresponds to the unfavorable interactions between DCB solvent and MEH-PPV. The polymeric chains minimize interfacial contact with solvent during the evaporation process by segregation into large domains. For the MEH-PPV chains dispersed in xylene, the magnitude of polymer-polymer interactions and polymer-solvent interactions is comparable (i.e. moderate solvent). Therefore, the formation of polymer droplets is much less in this case. This argument is consistent with the discussion in previous section, suggesting that the MEH-PPV chain is more collapsed in DCB. It is important to note that the number of polymer droplets does not reflect degree of interchain aggregation in thin films. There are other types of interchain association that do not lead to photophysical change of MEH-PPV [3, 5]. The films prepared by spin casting exhibit smoother surfaces as shown in Fig. 4,, However, the film obtained form the solution of DCB still contains more polymeric droplets compared to the film prepared from the solution of xylene.

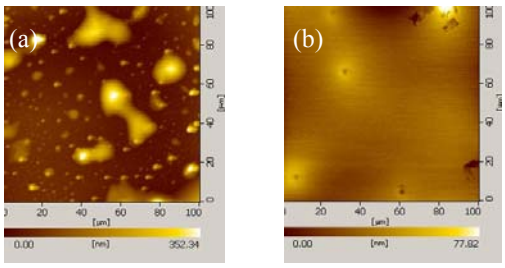

Figure 3. AFM topographic images of drop cast films prepared from 0.05 mg/mL MEH-PPV solutions. Solvents: (a) DCB and (b) xylene

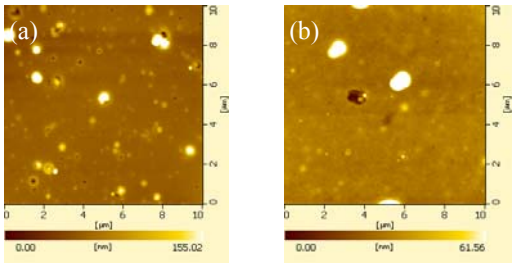

Figure 4. AFM topographic images of spin cast films prepard from 15 mg/mL MEH-PPV solutions. Solvents: (a) DCB and (b) xylene

The relationship between spin speed and thickness of MEH-PPV films are also investigated as shown in Fig. 5,. The film thickness decreases significantly upon increasing spinning speed from 1,000 to 3,000 rpm. Further increasing the spinning speed to 4,000 and 5,000 rpm slightly affects the film thickness, which range from 100 to 800 nm depending on polymer concentration and solvent. The varying of solvent and spinning speed also affects the root mean square surface roughness (RMS) of MEH-PPV films, which is one important parameter controlling the efficiency of the PV devices [8].

The higher surface roughness will give higher efficiency device which may result in a more efficient charge collection at the interface. Cause of the increase of contact area between the polymer film and metal electrode for the film with higher surface roughness [8]. It is known that the diffusion length of charge carrier in organic materials is often only a few nanometer[9] and on those carriers generated near the electrode will be collected and give rise to a photocurrent . Our results found that increasing spinning speed from 1,000 to 5,000 rpm causes the RMS roughness of MEH-PPV films prepared from 15 mg/mL solution of DCB to decreases from 18.61, 18.25, 23.94, 10.63 and 12.76 nm, respectively. The films made from solutions of xylene exhibit similar results. The RMS roughness of the films varies from 4.473, 9.091, 9.347, 2.471 and 10.81 nm upon increasing spinning speed.

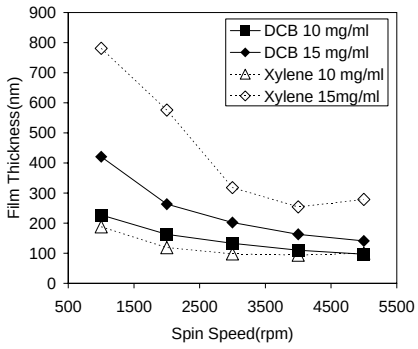

Figure 5. Film thickness of MEH-PPV film under different spin speed with concentration 10, 15 mg/ml from DCB and xylene solution.

The difference of RMS between DCB and xylene are in a range of 98%-969% relative to RMS of xylene. The difference is much. This result indicated that the area between polymer and metal electrode of devices from DCB is higher than xylene. We concluded from morphology study that device performance of the device made from DCB is higher than xylene solution.

Current density J(v) characteristics under dark and illumination modes of device fabricated from DCB and xylene solution concentration 10, 15 mg/ml are shown in Fig. 6 , and Fig. 7,Fig. 8, and Fig. 9 P_{max}, I_{sc} and FF represent maximum power output, short circuit current and fill factor, respectively, as a function of spin speeds. In this case the measured value of I_{sc} and P_{max} show an increase upon the rising spin speed, while not in the case of FF where the its trend is random. P_{max} represents for efficiency of device for this experiment because we did not measure the power incidence of the light source. P_{max} in these devices made from DCB and xylene solutions is

increaseing with the rising spin speed and film thickness but decreasing at the higher speeds of 4000 and 5000 rpm. In general, the optimum film thickness for organic solar cells is 100 nm. In our work, the film thickness for the best device performance made from DCB and xylene are 133, 100 nm with corresponding P_{max} of 0.137 and 0.033 μw, respectively. The higher optimum device performances of the film made from DCB solution is believed to have the larger contact surface area between the metal electrode and the film [8].

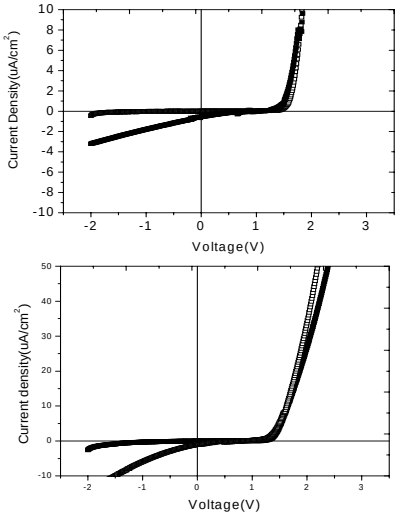

Figure 6. *I-V* characteristic under dark and illumination mode of device made from DCB (upper) and xylene (lower) concentration 15 mg/ml with spin speed 2000 rpm.

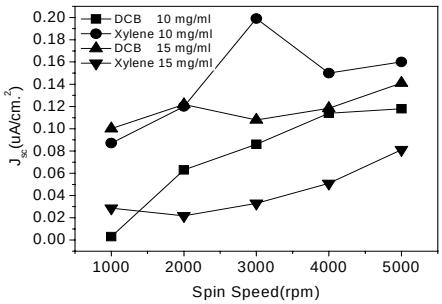

Figure 7. Short circuit current plot as function of spin speed of device made from DCB and xylene with concentration 10, 15 mg/ml.

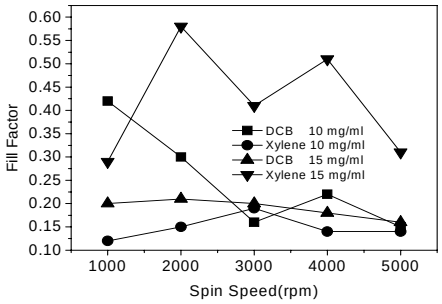

Figure 8. Fill factor plot as function of spin speed of device made from DCB and xylene with concentration 10, 15 mg/ml.

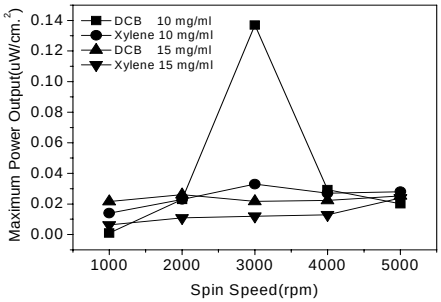

Figure 9. Maximum power out plot as function of spin speed of device made from DCB and xylene with concentration 10, 15 mg/ml.

We concluded that the RMS is an important role for the device efficiency enhancement.

Another factor for device performance is the degree of aggregation as mentioned above. It was found that the degree of aggregation in xylene solution is higher than DCB solution. Although both factors affect the performance of plastic solar cells, the RMS roughness seems to play a major role in the present case.

IV. CONCLUSIONS

We have found evidence that the degree of aggregation in solution of xylene is higher than DCB by Uv/vis and AFM study. The degree of aggregation can be controlled by factors such as spin speed and polymer concentration and choices of solvent. RMS roughness and film thickness is an important factor for optimal device performance.

Abstract **- In this paper, the opportunity and problems of human recognition through detecting body odor by using electronics nose (E-Nose) are presented. The developmental E-Nose system is a symmetrical reference-sample switching unit equipped with activated carbon cleaned air and constant high humidity produced by a humidity generator. An array consists of five metal-oxide gas sensors including humidity and temperature sensors. The measurement circuit uses the voltage divider resistor for each sensor. The principle component analysis method was used for pattern recognition. The sensitivity of the E-Nose system was compared with a human nose, to classify the strength of human body smell that can be mapped to different levels of artificial isovaleric acid normally produced by the human body. It was shown that the system can classify up to 4 levels of intensity. In this setup of air flow switching system and sensor chamber, it is only possible to detect strong human body smell. Also only two sensors have a useful reaction to the odors produced by the human body. To classify different persons it needs more dimensions of data this means more sensors that react. A classification and recognition of different persons with weak or normal body odor will be less efficient with this setup. The use of deodorant and different humidity of the samples disturb the recognition but can be solved by various techniques.**

I. INTRODUCTION

It is well known that humans recognize each other by to observe from the various characteristics of them such as face, voice or gait. The authentication in computer systems has been traditionally based on something that one has (key, magnetic or chip card) or one knows (PIN, password). However, tend to get stolen or lost and passwords are often forgotten or disclosed [1]. To achieve more reliable verification or identification we should use something that really characterizes the given person. Therefore, the biometrics system is proposed which recognizes a person based on a feature vector derived from a specific physiological or behavioral such as a fingerprint or a voice sample [2]. These characteristics are measurable, unique and should not be duplicable. One of the body odors is physical characteristics of human and scientists already have linked a collection of immunity sense with unique human body odor the able individual, and can be used to identify people [3], though this is more often done by dogs [4], However, dogs works only as well as his master and tedious work can lead to unreliability. Thus an ENoses to detect human body odor will be a suitable replacement of dogs [5]. Addition, ENoses sensitive enough to test beer, perfume sample and uncover pollution and disease. Since, an ENoses will be possible to identify persons [6]. From this idea, we interest to research about the body odor recognition and presented in this paper. The main purpose of this study was to identify persons by their body odor an ENoses must be used with opportunity and problems.

The paper is organized as follows: after the introduction presented in section I, the discussion is focused on body odor. Afterwards, the experimental setup is presented on section II and some results are presented on section III. The discussions are presented in IV. Finally, the paper conclusions are presented at section V.

II. EXPERIMENTAL SETUP

The setup is a symmetrical reference-sample switching unit with activated carbon cleaned air and constant high humidity produced by a humidity generator (bottle of water at a specific temperature within the air flow) as shown in Figure 1. The data acquisition is realized by a USB-DAQ-Card National Instruments NI USB-6008 and the measurement program is written in LabView 8.

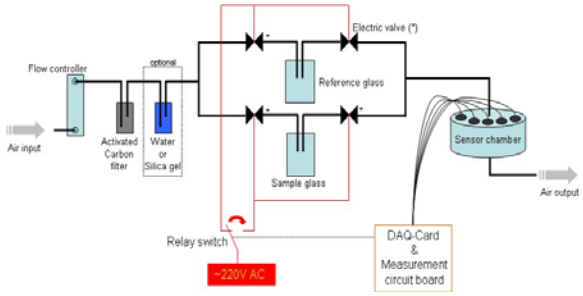

Figure 1 The reference-sample switching unit

It is necessary for this type of measurement to switch between a reference and a sample line. Therefore, four electrically controlled solenoid valves are used for this. Always two solenoid valves are open, the other two are closed. This ensures there is no mixing of the gas from the reference and sample line. It is also possible to remove the sample glass while the reference line is used without disturbance of the gas flow.

One digital output line of the DAQ card controls a "relay for remote" circuit board to switch 220V with a relay for the valves. The solenoid valves models are "Parker VE161-VE" with a magnetic coil "Parker Coil KT09 (220/230V – 9W)". The activated carbon filter remove alcohol, acetone and other aerosols from the air that can disturb the measurement if a pump and normal air of the room is used.

To control the humidity a bottle of water at a specific temperature to get a higher humidity or silica gel to reduce the humidity can be used.

A. Sensors chamber

The sensor chamber consists of a glass cylinder with a Teflon plate on top and bottom to seal the chamber. Both Teflon plates have an inlet or exhaust hole with a screw-in connector for standard plastic pipes. The top plate also holds the sensors and the connector (9-pin RS232) to connect the measurement circuit board. Under the inlet hole there is a small Teflon plate to avoid a laminar air flow from top to bottom. Under this turbulence plate there is a single-chip humidity / temperature sensor mounted. The connectors for this sensor go through the top Teflon plate but the hole is sealed with a special gum. The whole construction is set up on a cylindrical polystyrene stand for better stabilization. As show in Figure 2.

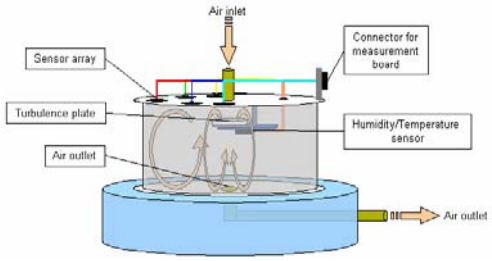

Figure 2 Sensor chamber layout

B. Sensor types

The sensors were chosen for react to body odor show in table I.

Table I: sensor was used choose

Sensor type	Detection of
TGS 813	Combustible gases
TGS 822	Organic solvent vapors
TGS 825	Hydrogen sulfide
TGS 880	Cooking vapors
TGS 2602	Air contaminants

The two possibilities to arrange the sensors for this kind of sensor chamber are first on the top plate and the second on bottom plate. It is easier to connect the sensors to a measurement board if the sensors are located on top plate of the chamber. The sensors are arranged around the air inlet and the turbulence plate will bring the gas to the sensors.

A single-chip Sensirion SHT15 sensor to measure humidity and temperature at the same time is mounted under the turbulence plate so it does not disturb the air flow to the other sensors. The turbulence plate and the SHT15 are mounted with the same screw to a small aluminum holder.

C. Measurement Circuit

The measurement circuit consists only of a voltage divider resistor for each sensor, the RS232 connector, a connector for the power supply and a connector to the DAQ card. The voltage is measured over a variable resistor to adjust a unique resistance for each sensor. The highest sensitivity to small changes of the sensor resistance is reached if the measurement resistor has approximately the same resistance like the sensor resistance with the reference gas / air. To keep the circuit and the connection to the sensors simple and use as less connectors as possible all sensors use the same voltage for the heater and the voltage divider. The connection principle show in figure 3 :

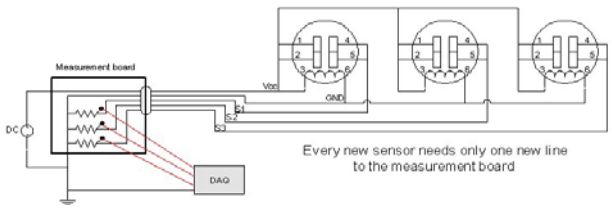

Figure 3 Measurement circuit board and connections

The sensor itself is between pin 1,2 and 4,5. The heater is on pin 3 and 5. The pin layout may differ for different sensor types but the connection principle is the same.

D. Measurement of different levels of artificial body smell

The first experiment it was necessary to find out the sensitivity of the e-nose system, especially the sensors, is comparable with a human nose.

To classify the strength of human body smell it can be compared to different levels of artificial isovaleric acid normally produced by the human body.

The subjective impression of the human nose is in a logarithmic scale and the concentrations of the isovaleric acid levels are also logarithmic to fit the subjective impression. But the sensors work linear and so the results should be recalculated into a logarithmic scale to see a linear slope of the result. A value scale in six steps from 0 to 5 is used to evaluate the intensity of the body odor which show in table II

Table II: the concentration of the isovaleric acid levels

Level	Isovaleric acid / water (ml / L)	Subjective impression
0	0	Nothing
1	0.013	Slight
2	0.053	Definite
3	0.22	Moderate
4	0.87	Strong
5	3.57	Very strong

E. Long-term measurement of armpit smell

The experiment time is 5 days with a sample collection of the armpit smell in the morning after waking up and in the afternoon 8 hours after the sample in the morning. The pad must be in direct contact to the armpit for 10 minutes for each arm and stored into a special sample glass bottles with a screw-on closure. Date and time must be noted on the sample glass bottles. The measurement should done as fast as possible after collection to avoid changes in smell due to bacteria.

The conditions for the person during time of experiment and one day before are:

- have a shower in the evening and in the morning after collecting the sample
- use of deodorant only in the morning after taking a shower and only on the right arm, leave the other untouched
- no alcohol and sex allowed
- no sports before afternoon sample collection
- no strong smelling food (e.g. durian or garlic)
- keep life and activities in same pattern

Each person has to collect the sample by itself.

III. RESULTS

The measurement results of different levels of isovaleric acid show below:

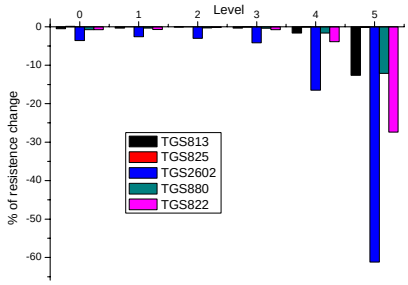

Figure 4 Different levels of isovaleric acid

Figure 4 shows that sensors can be detected on the strong smell (equal to isovaleric acid level 3, 4 and 5) and the highest sensitivity to body odor have sensor TGS822 and TGS2602. Mathematically adjusted results to eliminate the logarithmic scale of the levels by the formula: $Y = \ln(1 - \%R_S)$ which the result shows in figure 5.

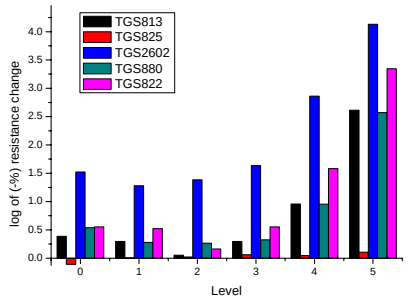

Figure 5 Logarithm of measurement result

The comparison between left and right arm on morning and afternoon (average of 5 days) show in figure 6 and 7, respectively.

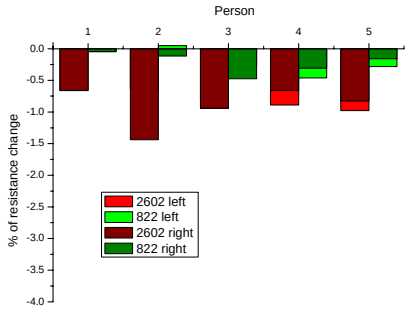

Figure 6 Morning comparison left-right arm

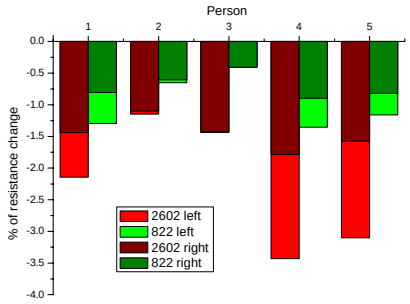

Figure 7 Afternoon comparison left-right arm

In the figure 6 and 7 show that the morning all persons have only a weak smell and there is nearly no difference between right and left arm. For some people a big difference between the left (without deodorant) and right arm (with deodorant) in the afternoon such as person 4 an 5. For person 2 and 3 have a naturally weak smelling. The effect of deodorant can be shown very good. The deodorant reduces the strength of smelling for persons with a strong smell (here in the afternoon).

The principle component analysis (PCA) method is used in this. The analysis result by PCA of: two person (person 4 and 5), afternoon, left and right armpit, over a period of 5 days show in figure 8.

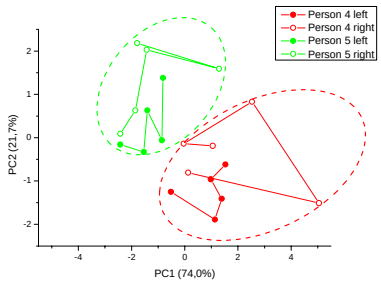

Figure 8 PCA-Graph of 2 different person

IV. DISCUSSION

The results of the isovaleric acid measurements show it is only possible to clearly detect level 4 and 5. Level 3 can be detected if the environmental conditions are very good. Not all sensors are sensitive to the isovaleric acid. The highest sensitivity have sensor TGS822 and TGS2602. The logarithmic scale of the isovaleric acid solution can be eliminated by calculations to show the sensors work linear.

For the human body smell measurements it is only possible to detect strong smells (equal to isovaleric acid level 3, 4 and 5). In the afternoon it is normal for people to have a strong smell if no deodorant is used. In the morning all persons have only a weak smell and there is nearly no difference between right and left arm. The "noise level" is at about 1% of resistance change for sensor TGS822 and 0.5% for sensor TGS2602. Maybe contaminated pipes disturb the measurement. With the PCA it is not easy to classify persons. The data of afternoon of the two persons with the strongest smell can classify these two different persons. If the data contains all persons only these two persons are different and the rest is very similar.

Also the contamination of the plastic pipes is a problem. After measuring a strong sample a weak sample produce a higher sensor response than it should do. Maybe replacing the plastic pipes with Teflon pipes reduces the effect. Also a good cleaning of the system is necessary after a measurement. . It is necessary to test different types of other sensors. The humidity is also a problem because different persons produce different humidity that can change all the time. So the best results can be reached if the background humidity is always nearly equal to the humidity of the sample.

V. CONCLUSION

The present setup is efficient to detect strong human body smell. The capability to recognize and distinguish weak body odor is yet to be explored. In this setup, only two sensors are effective to the odors produced by the human body. To classify different persons it needs more dimensions of data this means more sensors that response. A classification and recognition of different persons with weak or normal body odor is the scope of future development as well as the use of different deodorant.

Abstract— **Lighting system has been designed for enhancing orchid growth rate. Light sources have been implemented from low-cost red (λ~640nm) and blue (λ~470nm) light emitting diodes. Optical sensing and feedback techniques with active-RC lag compensator have been deployed to maintain photon flux density to the desired values 4.9 μmol m^{-2} s^{-1} and 14 μmol m^{-2} s^{-1} for blue and red lighting conditions regardless of ambient luminous condition or changes in LED output over time and temperature fluctuation. Experimental results clearly show that the orchid baby seedlings subjected to additional red and blue lights outgrow those cultivated under normal lighting condition.**

I. INTRODUCTION

It has been widely known that plants' basic need for light reside within three spectral ranges responsible for photosynthesis, phototropism and photomorphogenesis, respectively. Photosynthesis requires light in the vicinity of the absorption peaks of chlorophylls a and b (at 662 nm and 642 nm, respectively), which are the most important photosynthetic pigments. Phototropic processes, which control motion of plant organs in response to light and ensure optimization of biophysical and biochemical reactions, are triggered by light with wavelengths in the range of 400–500 nm. Finally, plant morphogenesis, encompassing processes such as shooting, pigment synthesis and healthy plant development, depends on far-red radiation in the range of ~ 730–735 nm.

For many decades, many researchers around the world have been carried out to investigate how light spectrum affect plants' growth rates and their properties based on plant's photobiology (photosynthesis, photomorphogenesis and phototropism) [1-8]. To the best of authors' knowledge, not much research has focused on cultivation of Thai orchid under various or combination of light spectrum. Thailand's export values of orchids each year exceed USD 30 million thanks to the plants' unique beauty and originalities. Techniques that help enhance orchid's growth rate and productivity would be truly beneficial to the orchid industry. The techniques may open huge possibility of commercial indoor plantation under a well-controlled environment which is no longer season dependent. The products can be continuously supplied throughout the year and satisfactorily serve for high market demand. This study presents preliminary results on how light at particular wavelength affects orchid growth. The findings presented here might change the way orchid farmers grow their plants more effectively and profitably.

II. LIGHTING SYSTEM DESIGN

Schematic of the lighting system is illustrated in Fig. 1 where a current source comprising PMOS M1 (IRF9540) and Rs is switched at the base of PNP Q1 (TIP2955) by pulse trains coming from a pulse generator to provide an appropriate amount of current to clusters of light emitting diodes (LEDs) via improved-Wilson current mirrors Q2-Q5 (one current mirror per cluster containing five LEDs). LEDs are particularly well suited for plant growth, as opposed to fluorescent or incandescent lamps, as they have an extraordinary life (about 100,000 hours), require little maintenance, and radiate little amount of heat. The pulse is generated by PIC microcontroller 16F877A (with additional circuitry for adjusting logic level from 0-5V to 0-12V) where frequency (10Hz – 100kHz) and duty cycle (0% – 100%) can be independently varied. The maximum current supplied to the LEDs can be adjusted by selecting suitable degenerate resistor Rs and gate voltage of PMOS M1 as given by (assuming that this happens when the pulse logic is low and M1 is in a saturate strong-inversion mode and Q1 is switched on to allow drain current of M1 to flow into the current mirror at the bottom)

$$I_{\max} = \frac{1}{R_S}\left(V_{CC} - |V_{TP}| - V_G + \frac{1}{R_S\beta}\right) + \frac{1}{R_S^2\beta}\sqrt{1 + 2R_S\beta\left(V_{CC} - |V_{TP}| - V_G\right)} \quad (1)$$

where V_{TP} and V_G are threshold voltage and gate voltage of M1. The parameter β being a PMOS device constant and it is approximated to be 2 for IRF9540 (extrapolated from datasheet).

The Red LED is of LTL2R3SEK model which is made with AlInGaP technology and it emits visible red light with a dominant wavelength of 640nm. The blue LED is of TOL-50aUBdCEa-ETB6 made from AlGaN/GaN rendering blue light with peak wavelength of 470nm.

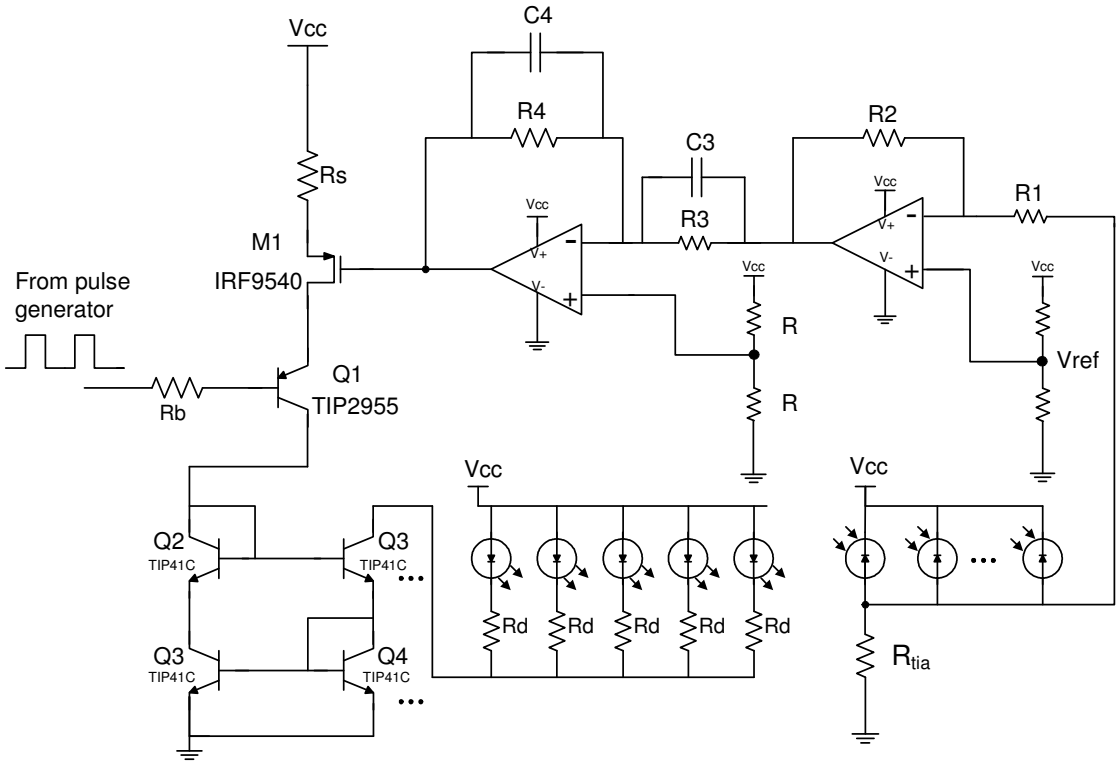

Fig. 1 Schematic of the orchid lighting circuitry.

To maintain photon flux density at desired level, a feedback loop is employed to adaptively vary gate voltage of M1 in order to encounter variation of ambient light. The output light intensity is sensed by an array of Silicon PIN photodiode (model SFH203) and the resulting voltage is compared with Vref (set at Vcc/2 = 6V) by the first amplifier. The amplifier's output voltage is then fed to a lag compensator implemented from a single opamp, R3, R4, and C3, C4 and its corresponding s-domain characteristic is simply described by

$$T(s) = -\frac{C_3}{C_4}\frac{\left(s+\frac{1}{R_3C_3}\right)}{\left(s+\frac{1}{R_4C_4}\right)} \qquad (2)$$

where $R_4C_4 > R_3C_3$. The operational amplifiers employed for this system are LF353N and they have been designed so that their nominal DC input and output voltages are at Vcc/2 = 6V.

With 1kHz pulse and 50% duty cycle, the resistor R_{tia} is selected to maintain photon flux density at 4.9×10^{-6} mol m^{-2} s^{-1} and 1.4×10^{-5} mol m^{-2} s^{-1} for blue and red lighting conditions respectively while each of both type of LEDs draws average current of 70mA from 12V supply. The design component values are listed in Table 1.

Fig. 2 confirms proper functionality of the light intensity stabilizing feedback loop where the voltage at the photodiodes' anodes can be successfully maintained at 6V despite the ambient light has been subjected to significant change (extra light source controlled by 10-Hz pulse has been employed to imitate ambient light fluctuation).

Table 1: Design parameters

Parameters	Red Lighting	Blue Lighting
Rb	1 kΩ	
Rs	5 Ω	
Rd	100 Ω	
Rtia	500 kΩ	1000 kΩ
R1	10 kΩ	
R2	100 kΩ	
R3	10 kΩ	
R4	100 kΩ	
C3	10 nF	
C4	10 nF	
R	10 kΩ	

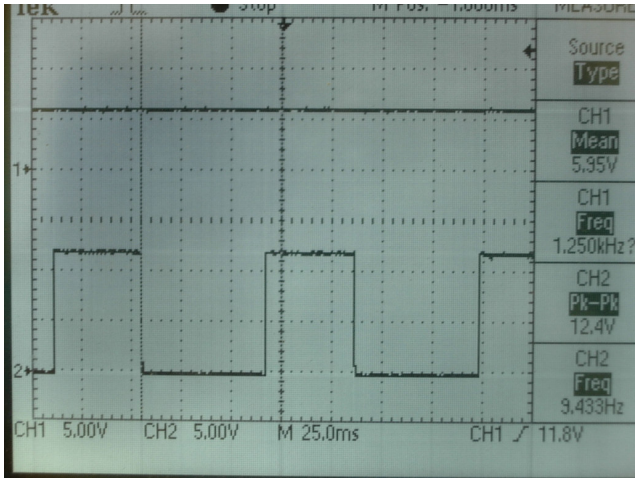

Fig. 2 Oscilloscope captures a stabilised voltage at 6V (top) at photodiode's anodes compared to the circuit without feedback (bottom).

III. EXPERIMENTAL RESULTS

The experiment setup is as shown in Fig. 3. It is important to note that the experiment has not been carried out inside a dark room. This is because we expect orchid farmers to employ this system within a usual growing environment. The main purpose is to see whether *additional* blue and red lighting can help improve orchid development compare to typical lighting condition. Orchid species under study is Rhybchostylis gigantean (or 'Red Elephant' in local name). Exposure period is between 6hr to 18hr with twenty baby seedling samples for each lighting condition (red, blue, normal).

From photographic comparison in Fig. 4, it can be seen that the seedlings subjected to blue and red light outperform those under normal lighting condition in various aspects including leaf area, number of leaves, root size, number of roots as numerically charted in Fig. 5.

IV. CONCLUSION AND FUTURE WORKS

Lighting system has been designed for enhancing orchid growth rate. Optical sensing and feedback techniques with opamp-RC lag compensator have been deployed to stabilise photon flux density to the desired values taking into account ambient lighting fluctuations, LED properties that drift with temperature or time. Preliminary experimental results clearly show that the orchid baby seedlings with additional red and blue lighting exposure outgrow those cultivated under normal lighting condition. Due its modularity of the implemented building blocks, the system can be straightforwardly expanded for the purpose of mass production. Future work should include investigation on different species of orchids at various stages of its life. Multiple wavelength sources (red, green, blue and infrared) could be combined to produce specific spectrum requirement for the experimental purpose in order to figure out the optimum light mixture for particular species of orchid. It is also of great interest to not only foster plant growth, but to *control* plant growth. The supplementation of specific wavebands or skewing of overall spectrum may help modulate the progression of plant development events. The possibility that combinatorial light regimes may help to optimize growth and control developmental transitions makes the presented concept particularly attractive to the design of controlled environments targeted to plant production for aesthetic applications, or applications relevant to human nutrition. If spectral quality alone can delay or hasten the floral transition it may have profound effects on modulating the delivery of nursery goods or perhaps affect the availability of consumable produce in a finite, controlled environment.

***Abstract*- In this work, we have developed a gas sensor array for effective odor monitoring, measuring, recognizing and analyzing systems. The odor sensing system consists of four main components: gas flow system, gas sensor array circuit, microcontroller, and computation. The system is made compact and portable by suitable electronic design. Several small commercial gas sensors and simple voltage-divider sensing circuit are employed. A low cost microcontroller system is designed to process time-multiplexed sensor signals, calculate gas concentration, generate output to the computer, and analyze gas concentration. Principal Components Analysis (PCA) technique is used to investigate relationships between the individual points in the data set. The system has been tested toward orange juice odor. It has been able to recognize and distinguish different odors of fresh and rotten orange juice with satisfactory accuracy.**

I. INTRODUCTION

Recently, the demand of various gas sensing applications including alcohol driver testing, environmental monitoring, and agricultural product's odor testing have been considerably increased. Thus, effective monitoring and controlling systems for detection and quantification of various gases or vapors have gained much attention. Analytical instruments such as gas chromatography /spectroscopy, which provide precise analysis, are time consuming, expensive, and non-portable. Semiconductor gas sensor is among the most widely used commercial gas sensors due to their low cost, high sensitivity, fast response, and simple electronic interface. However, a single gas sensor cannot be used to identify the specific gas and determine the corresponding concentration because it has limited gas sensing selectivity. The concept of gas sensor array has been proposed for effective gas monitoring, measuring, recognizing and analyzing systems and a number of such systems have been developed. In this work, we have developed an electronic nose with compact electronic design comprising only one microcontroller that generates a basic function to implement Principal Component Analysis (PCA) with the commercial complier. Principal Components Analysis (PCA) technique is used to investigate relationships between the individual points in the data set. In this case, we have developed e-nose system particularly for agricultural product testing. It can be used to distinguish odors between fresh orange juice and ripe orange juice. The objectives of this application are to improve the quality of fruit products of Thailand and utilize a new technology to reduce the farmer problem in the future.

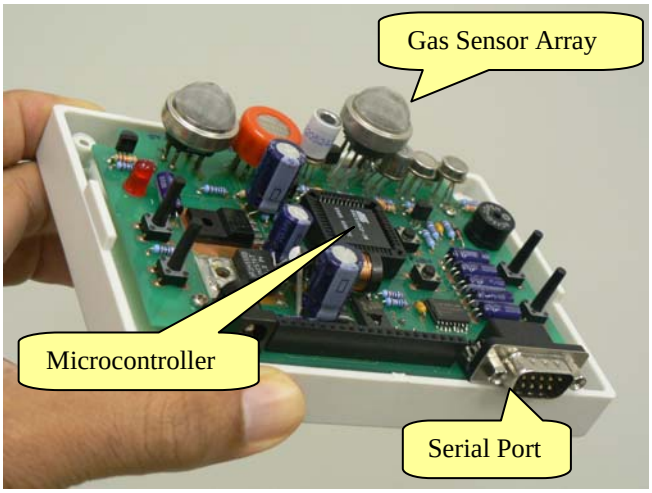

Figure 1. Photograph of an Electronic Nose System.

II. GAS SENSOR OPERATING PRINCIPLE AND CHARACTERISTICS

A. General

Gas sensor is generally operated based on a change of its electrical characteristics as a result of gas interaction with the sensing element. Semiconductor gas sensors utilizing the transduction of a chemical reaction between the gas species and semiconductor materials into electrical resistance change are the most widely used commercial gas sensors.

Semiconductor gas sensor is typically a resistor made of metal oxide materials that is sensitive to different target gases. The common sensing materials are SnO_2, WO_3, etc., typically containing a wide variety of dopants or catalysts to enhance

gas-sensing sensitivity and selectivity. In addition to gas sensing material, there must be a built-in heater to heat the gas sensor to operating temperature between 200 and 400 °C. The heating element is usually made of Pt thin film or NiCr wire.

B. Sensing Circuit

The resistance of the gas sensor is measured through a simple voltage divider circuit given by.

$$R_S = \frac{V_{CC} + V_{RL}}{V_{RL}} \quad (1)$$

where V_{RL} is the voltage across of the load resistor, R_L, and V_{CC} is the supplied voltage.

The gas sensor is heated to a fixed operating temperature, which is typically 300-350 °C by the V_{CC} heating voltage. The heating voltage is controlled by on-off mechanism to maintain a constant temperature.

C. Calibration

The characteristics of commercial semiconductor gas sensor are largely varied depending on material and fabrication process. Due to base line drift behavior of these sensors, their characteristic is characterized in term of relative resistance change, which is known as sensitivity. Gas-sensing sensitivity, S, of a semiconductor gas sensor is normally defined as the ratio of resistance with no gas sample to that with gas sample:

$$S = \frac{R_S}{R_O}, \quad (2)$$

where R_S is the resistance with gas sample and R_O is reference sensor resistance at a given gas concentration. The sensitivity strongly depends on gas concentration and operating temperature of the sensor.

D. Algorithms

A microcontroller is used to process sensor signal, calculate gas concentration, and generate output to computer. The algorithms for microcontroller software have 2 modes. First, the controller is initialized by waiting for 10 seconds to let the sensor be heated to its operating temperature. During the calibration mode, the microcontroller calculates the input resistance, maps the results to the known input concentration, and stores the calibrated data into the sensor's characteristic table. In the normal operating mode, the microcontroller continuously samples and reads output voltage, V_{RL}, from sensing circuit via Analog-to-Digital Converter (ADC). The ADC has multiple channels so that it can be connected to multiple sensing circuits for various sensors and the microcontroller can time-multiplex different sensor input signals by simple periodic addressing. Software programmed in the controller then performs calculation to convert the voltage into resistance, sensitivity, and gas concentration. The gas concentration is determined from calibration table. The final data set output are secured and convert into a protocol message send to computer serial port with computer interface unit. The computer analyzes data set using PCA technique in order to recognize odor. The calculated results are displayed on the PCA graph with the odor group.

III. GAS SENSOR ARRAY

A single gas sensor cannot be used to identify the specific gas and determine the corresponding concentration because it has limited gas sensing selectivity. The gas sensor array is the array of difference type of gas sensors. Each sensor is highly responsive to different a target gas while each sensor has lower response to other gases. At a result, it can provide the identified output characteristics of each odor similar to the human nose. The list of commercial gas sensors in the array is shown in TABLE I.

TABLE I
LIST OF GAS SENSOR IN THE ARRAY

No	Sensor	Target Gas
1	TGS2620	Alcohol
2	TGS825	Hydrogen Sulfide
3	TGS826	Ammonia
4	MQ3	Alcohol
5	MiCS2710	Nitrogen Dioxide

IV. GAS FLOW SYSTEM

The main structure of gas flow system is shown in Figure 2. First, sample air is entered into this system by a pump whose flow rate is controlled by a mass flow controller in order to obtain more accurate detection. In the next progress, air sample flows directly into the filters that consist of 2 parts, activated carbon filter to clean the air and water/silica gel to provide the steady humidity. After that, purified air will be drained into reference gas or sample gas chambers by 2 different valves controlled by an electronic selector to prevent surplus gas return. As valve1 and valve2 are opened, the purified air is passing through the reference gas chamber and then into the mixing chamber. On the other hands, if valve3 and valve4 are opened, process will be the same. During these steps, Valve1 and valve3 will be closed to block returning air. In the last progress, the reference gas or sample gas will flow into the mixing chamber that consists of many types of gas sensors for monitoring, measuring, and analyzing signals fed from sensors.

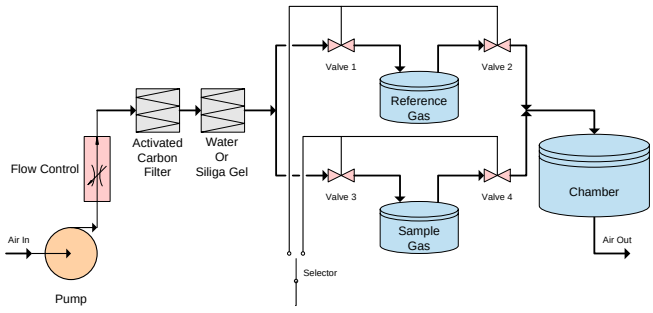

Figure 2. Diagram of a gas flow system.

V. Principal Component Analysis (PCA)

Principal Component Analysis is a useful statistical technique for applications in various fields, such as face recognition, image compression, and pattern recognition for data of high dimension such as odor. Statistic is based around the idea to analyze them in terms of the relationships between the individual points in a big set of data.

The mean X used to indicate the average value of each data set. It does not tell us a lot about the data except for a scale of data. The spread of data is difference. The standard deviation (s) of a data set is a measurement of how spread out the data is. Variance (s^2) is simply the standard deviation squared and almost qualitatively identical to the standard deviation.

$$s = \sqrt{\frac{\sum_{i=1}^{n}\left(X_i - \overline{X}\right)^2}{(n-1)}} \tag{3}$$

The two measures are purely 1-dimensional. In contrast, covariance is always a measure between 2-dimensions.

$$\mathrm{cov}(X,Y) = \frac{\sum_{i=1}^{n}\left(X_i - \overline{X}\right)\left(Y_i - \overline{Y}\right)}{(n-1)} \tag{4}$$

If we have a data set more than 2-dimensions, a higher dimension measure is defined by

$$C^{n\times n} = \left(c_{i,j}, c_{i,j} = \mathrm{cov}\left(Dim_i, Dim_j\right)\right) \tag{5}$$

Where $C^{n\times m}$ is a matrix with n rows and m columns, and Dim_x is the x^{th} dimension. This matrix consists of the relationships between the data sets. We shall look at eigenvectors and eigenvalues of a given matrix. These are rather important, as tell us useful information about our data. Eigenvectors appear as diagonal dotted line on the plot. It provides information about the patterns in the data while eigenvalues are the ones that pointed down the middle of the data. It is the most significant relationship between the data dimensions.

The PCA process consists of five main steps. The first step is data acquisition. In this case, gas concentration data set is read from each sensor via ADC and the data is stored in 2-D array versus sampling time. Subsequently, data for each sensor is subtracted by their mean values and covariance matrix of the subtracted data is computed. The eigenvectors and eigenvalues of the covariance matrix are then calculated. Finally, the principle components are chosen and featuring vectors are formed.

VI. Experimental

During the start-up period when the power has just been applied to the sensor and system, the sensor is heating up and not stable for operation. The stable waiting time must be determined to notify the user that the sensor is ready for operation. In general, the gas sensor characteristic will enter a stable period after applying heating power for ~ 5 seconds.

The electronic nose system was then tested for fresh and rotten orange juice vapor detection by standard flow through technique. Synthetic air is bubbled through that odor solution in water with a flow rate of 0.5 liter/min and flow through the gas sensors. The sensor output is continuously calculated to obtain gas concentration and sent to the computer by the microcontroller. Typical dynamic response of gas sensing measurement toward fresh and rotten orange juice vapor obtained from the mobile gas-sensing system is shown in Figure 3 and Figure 4. From the typical dynamic response, the difference in data set between fresh and ripe orange juice odor cannot be noticed. To identify the difference, the data sets are analyzed by Principal Component Analysis technique. Figure 5 demonstrated the corresponding results from PCA analysis. The results show that the data from fresh and rotten orange juice can be effectively identified by PCA because two data sets can be completely separated in the PCA domain.

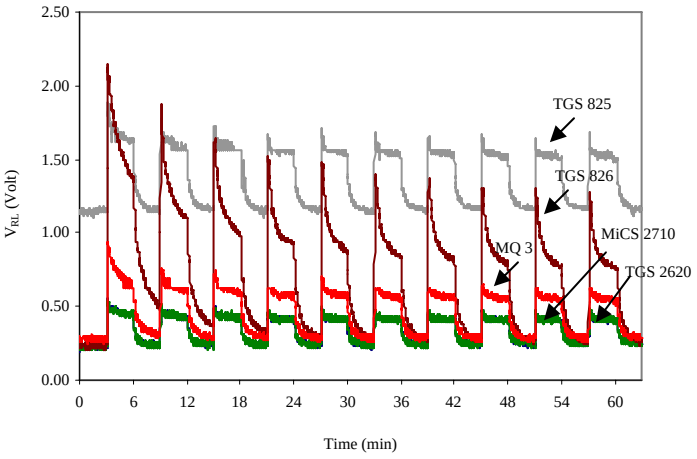

Figure 3. Typical dynamic fresh orange juice sensing response.

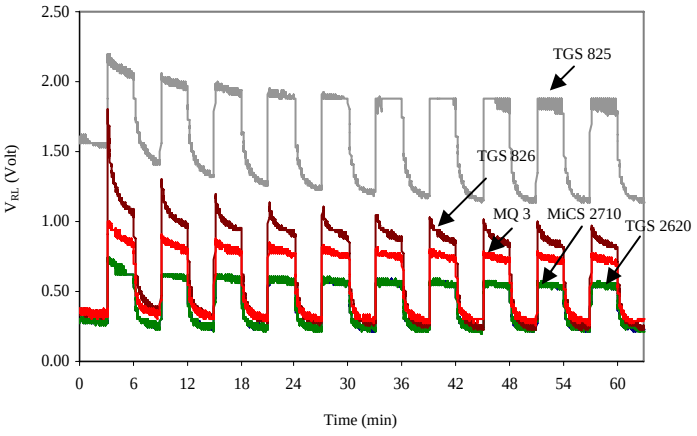

Figure 4. Typical dynamic ripe orange juice sensing response.

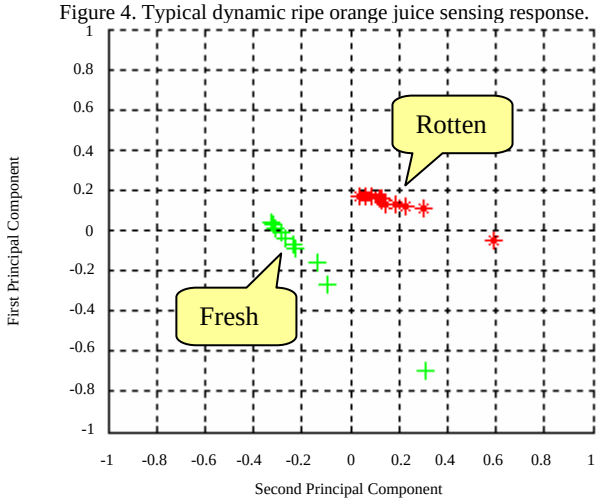

Figure 5. A plot of PCA result data.

VII. Conclusion

In conclusion, we have developed an electronic nose for effective fruit juice freshness recognition by deployment of commercial gas sensor array with compact electronic design for portable uses. The portable electronic nose system employs several small commercial gas sensors and low cost microcontroller system. The system processes sensor array inputs by time division multiplexing, calculates gas concentration, generates output to computer, and analyze gas concentration by applying Principal Components Analysis (PCA) technique used to investigate relationships between the individual points in the data set. In this case, the system is able to recognize between fresh orange juice and rotten orange juice. The tested system has shown satisfactory performance for typical ethanol vapor sensing. The successful application of the portable e-nose system will improve the quality of fruit products of Thailand and increase the use of new technology for farmer problem reduction.

***Abstract*- This paper presents the design and implementation of a heart rate monitoring system. This microcontroller-based system is developed for researches on fitness exercises, such as a a study of the relation between heart rates, energy expenditures, and intensity levels of aerobic exercises. The proposed system can be used for a long distance and support multi users where as most commercial heart rate monitor products support only short distance (using magnetic resonant from coil to communicate between transmitters and receivers) and are designed for individual or personal uses. The developed system, based on RF 2.4 GHz GFSK transceiver modules, can support multi channels up to 125 users. A simple threshold level detection algorithm is used to measure R-R interval of inputs from an ECG simulator. Results of heart rates computed from this algorithm correspond well with the known heart rates from ECG simulator. Single channel tests demonstrate that data can be transmitted and received successfully. Indoor and outdoor effective distances tests verify that the system can be used acceptably well up to a distance of 10 meters indoor and 100 meters outdoor. Multi channel tests yields proper functions and performances as expected.**

***Keywords*- Microcontroller, Electrocardiograph, Wireless system, Heart rate monitor**

I. INTRODUCTION

In sport sciences, it is well known that suitable exercise is a crucial factor to become healthy. One popular indicator for good health and appropriate intensity exercise is heart rate. A heart rate monitor (HRM) is a device used to 1) measure exercise stresses or intensity levels 2) monitor patients with obesity during their weight loss programs 3) monitor patients during their cardiac rehabilitation. Commercial HRMs [1] are widely available at various prices depend on specified features. Most commercial HRMs support only short distance monitoring since their main communication technology between transmitters and receivers is based on magnetic resonant from coil. Although HRMs can be developed in various ways [2]-[6], in general, they are designed for individual or personal uses.

Our main objective for this work is to design and implement a HRM system for fitness exercise researches. For this application, a HRM needs some additional features such as long operating distance and it must support multi users. For example, in aerobic exercises, there are many HRM users at the same time within a close distance. In such case, each device interferes other near by devices. With these specific requirements, commercial products are not suitable for our purposes. We propose to use RF 2.4GHz GFSK transceiver modules which support multi devices up to 125 channels, operates at much lower power consumption when compare with other 2.4 GHz devices such as Bluetooth or WLAN, and can be used for our long range requirement (up to 100 meters). Table I gives a general comparison of wireless technologies.

TABLE I
COMPARISON OF WIRELESS CONNECTION TECHNOLOGIES

Type	Coil	RF module	Bluetooth	Wireless LAN
Range	1 m	100 m	10 m	100 m
Speed	N/A	250kbps - 1Mbps	1-2 Mbps	11-54 Mbps
Power Consumption	Low	Low	Medium	High
Frequency	5 kHz	2.4 GHz	2.4 GHz	2.4 GHz
Cost	Low	Low	Medium	High

Figure 1 illustrates the overall concept of the HRM system developed for fitness exercise researches. Each pair of TX and RX must be set at different frequencies and addresses. Heart rate data on each receiver is transferred to a PC for further analyses, in either online (real-time) and offline modes.

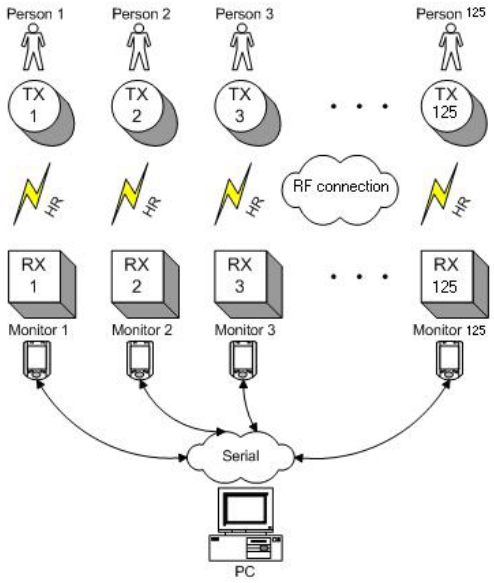

Figure 1. Heart rate monitor system for fitness exercise researches

II. MATERIALS AND METHODS

A detail of one channel HRM, composes of transmitter (TX) and receiver (RX), is shown in Figure2.

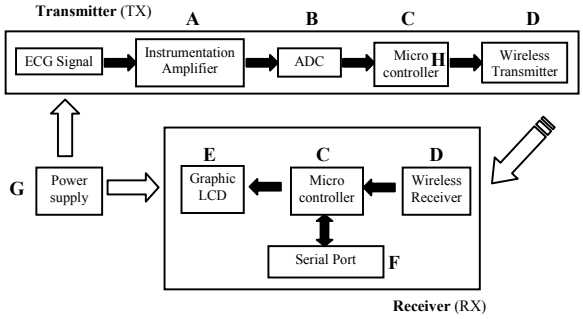

Figure 2. Block diagram of the single channel system

A. *Electrocardiograph (ECG) Instrumentation amplifier*

The ECG level is quite low in the range of a few mV. It has to be amplified to match with the input level of an analog to digital converter (ADC) for better resolution. A high precision and low offset instrumentation amplifier MAX4194 from Maxim Integrated Products, Inc [7] has been selected. This IC operates with a single 3 volts power supply.

The ECG amplifier gain can be set by selecting the value of one resistor (R_G). For our application R_G is initially set to 100 ohms to give a voltage gain of 500.

B. *Analog to digital converter*

The amplified ECG signal is digitized by the microcontroller internal 10 bits ADC. The ADC has maximum sampling rate of 15ksps, 1.5LSB absolute accuracy, 1LSB and 0.5LSB integral and differential nonlinearity respectively.

In this work the sampling rate is set at 500sps at 10 bits resolution which is 5 times of the ECG signal bandwidth (typically around 100 Hz).

C. *Microcontroller*

In this system, a microcontroller, is used in two separate parts of the system; Transmitter (TX) and Receiver (RX).

For the transmitter, the microcontroller processes ECG signals and detect heart rates using simple threshold level algorithm. After R-R intervals are detected, it is then used to calculate for instantaneous heart rates. Then the heart rate data is sent to the RF part for wireless transmission.

For the receiver, the microcontroller receives data from the RF part. Then data is sent to be displayed through a graphic LCD. Further analysis of the heart rate data on a PC can be done by interfacing these data through a serial port.

Microcontroller used in this system is ATMEL ATMEGA16 [8]. This chip includes flash memory 16 kB, internal RAM 1 kB, and a 10 bit ADC. In our application the microcontroller runs at 8 MHz clock and operates at 3 V supply. All program codes are in C programming language.

D. *RF transmission*

Laipac TRW-2.4G [9] wireless RF modules are used for sending and receiving data between transmitters and receivers. The operating frequency is 2.4 - 2.524 GHz ISM band, GFSK, and the data rate can be configured at either 250kbps or 1Mbps. This module supports frequency hopping and multi channel up to 125 channels. An interface to a microcontroller is obtained via a 3-wires serial bus. The RF output power can be adjusted from -20dBm to 0dBm (5dBm/step).

In this application, data rate is set at 250kbps and the output power is set to maximum (0dBm).

E. *Graphic LCD Display*

A Nokia 3310 Graphic LCD spare part [10] which is low cost and commonly available locally is selected to display heart rates and show menu of the heart rate monitor. This display has resolution of 84x48 pixels and can be interfaced through SPI bus. It can be configured to show characters in text mode as 14 columns x 6 rows.

F. *Serial Interface*

A PC interface to a microcontroller is required for acquiring either real time (online) or offline data for further analysis. In this work, the microcontroller interfaces to a PC via a serial port at 38400 bps, in 8 bits data format, no parity bit, and using 1 bit stop bit. At the PC, a LABVIEW program is used to display real time ECG signals.

G. *Power Supply*

This system operates with only a single 3 volts power supply from 2 AA batteries. The average current consumption of the system is approximately 20 mA.

H. *Heart Rate Calculation*

Figure 3 depicts the calculation of instantaneous heart rate from the R-R interval measurement (time between peak to next peak of ECG signals).

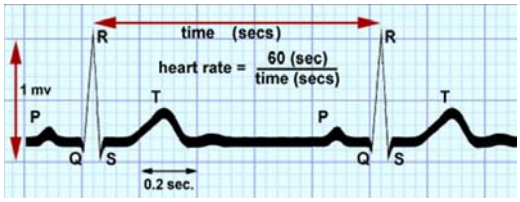

Figure 3. Heart rate calculations from R-R interval

III. EXPERIMENTS AND RESULTS

Experiment to verify system operations was divided into 3 parts; transmitter, wireless connection, and receiver parts.

1. *Transmitter(TX) part*

The amplified ECG signal measured by a 200 Msps DL1520 Yokogawa oscilloscope, as shown in Figure 4, shows that the gain of 500 is adequate for signals from an ECG simulator used initially in this experiment.

From Figure 4, the R-R interval = 496ms, using equation in Figure 3, gives heart rate = 60/0.496 = 120 beats/second.

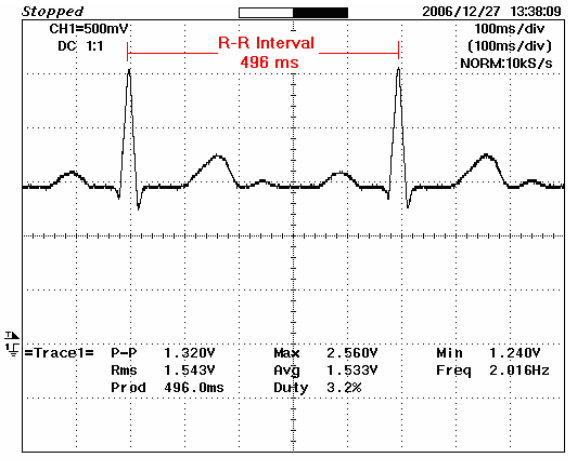

Figure 4. ECG signal at the instrumentation amplifier output

To verify that the ADC part is working properly, the digitized signal is sent through a serial port to be displayed on a PC. Figure 5 shows the digitized data, plotted by LABVIEW, from the microcontroller.

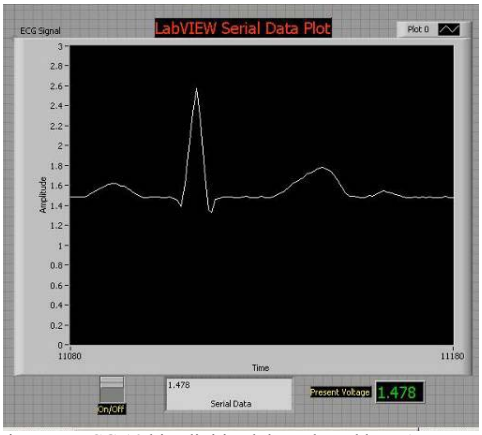

Figure 5. ECG 10 bits digitized data plotted by LABVIEW

The digitized ECG signal is then fed to the microcontroller which is running R-R interval detection program. The algorithm used to detect R-R interval is a simple threshold level detection method. More sophisticated and more robust algorithms can be used with the trade off of computational times. But for this initial test we will employ a simple algorithm to verify the concept of the proposed system. Figure 6 shows some heart rates which correspond well with those calculated from ECG simulator displayed in Figure 4.

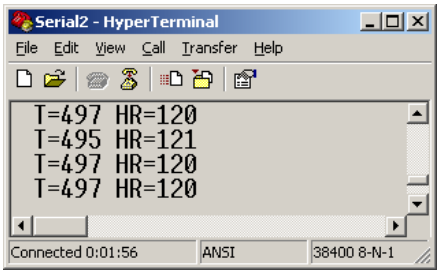

Figure 6. Heart rate calculates from microcontroller.

2. *Wireless connection part*

2.1 Operating Ranges Test

2.1.1 Indoor range, the RF wireless connection was tested for operating range with maximum RF output power, 0 dBm. By monitoring and comparing 350 Bytes data at serial ports of the transmitter and receiver. Byte-to-byte comparison is performed while the distance is varied until data differences occur. An indoor operating range of 10 meter can be achieved without data differences. Figure7 shows that the 350 bytes of sampling data at the transmitter and receiver are exactly the same at a 10 meters distance.

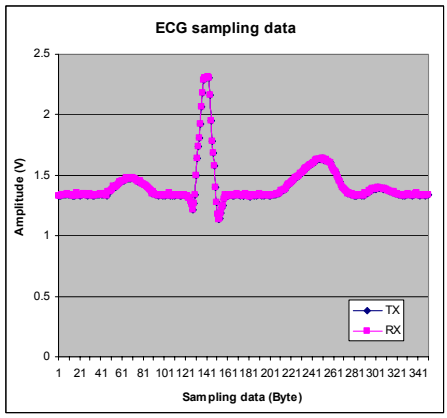

Figure 7. ECG sampling data from transmitter and receiver

2.1.2 Outdoor range, experiments were repeated for outdoor at the same RF output level. Test results show that maximum effective range is approximately 100 meters. This is considerably lower than the given specifications of the RF modules (200 meters for 250 kbps data rate). This may be caused by the test conditions and surrounding environment is not optimum. However, this operating range should be enough for our applications which are mostly outdoor activities.

2.2 Multi Channel Tests

Multi channel experiments, with 2 transmitters and receivers, are performed to verify their functionalities. This test can be divided into 6 cases as given in Table II.

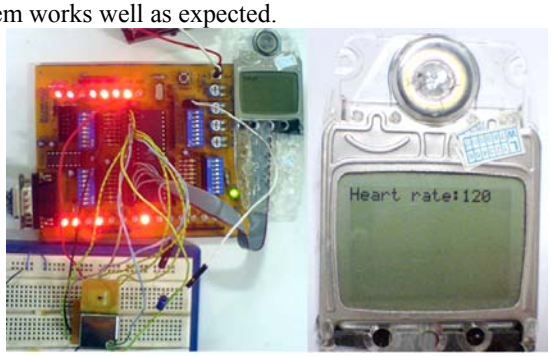
TABLE II
MULTI CHANNEL TESTS FOR RF WIRELESS CONNECTION

Conditions	Configurations	Results
Same frequency Same address	TX1 ↓ RX1& RX2	Both RX get same data
	TX1&TX2 ↓ RX1	RX1 get some cross data from TX2
Same frequency Different addresses	TX1 ↓ RX1& RX2	Only RX1 (same address with TX1) get data
	TX1&TX2 ↓ RX1	RX1 get some data from TX1 due to interferences from TX2
Different frequencies Same address	TX1 TX2 ↓ ↓ RX1 RX2	Both perform well No interference & cross channel
Different frequencies Different addresses	TX1 TX2 ↓ ↓ RX1 RX2	Both perform well No interference & cross channel

From test results in table II, when multiple devices are used with different frequencies, the system works well and there is no interference between near by devices. But for the case which using the same frequency, such as single RX and multiple TXs, the RX gets interfered data or loses some data. And for a single TX and multiple RXs case, all RXs can get all correct data without interfering other devices. Address setting is used to set identity of each pair of TX and RX.

3. Receiver(RX) part

The overall system is tested by feeding ECG signals from an ECG simulator to a transmitter and monitoring data at the receiver. Figure 8 (a) shows a receiver board that displays heart rate on a Nokia 3310 graphic LCD. The displayed heart rate, in Figure 8 (b), is the same as calculated previously at the transmitter part in Figure 6. This result shows that the overall system works well as expected.



(a) (b)

Figure8. a) A receiver board b) A Nokia 3310 graphic LCD display showing the received heart rate.

IV. Discussion

For the ECG instrumentation amplifier part, the actual measured gain is 495 which a little bit lower than the calculated value due to the tolerance of the resistor R_G. This is not critical since we can change the gain to any desired values by changing the resistance of R_G.

For low power consumption operation, we design to use a microcontroller to operate at a low voltage supply (3V) and reduce clock speed to run at 8 MHz clock. System performances can be improved by trading off of the power consumption constrains.

According to the RF 2.4GHz GFSK transceiver modules datasheet, this module has features for switching frequency channel which support multi devices. However, from our experiments, it is found that adjacent channel frequencies may interference each other. For optimal and error free connection, the system should be set so that there is a frequency space (1-2 MHz) between adjacent channels. This will reduce the total number of channels that can be used at the same time. However, this problem can be fixed by employing frequency hopping to share bandwidth between channels.

Since this system is powered by 2 AA batteries, voltage drop may occur if used for a certain period of time. This affects the level of reference voltage at the ADC and may result in sampling data error. A boost converter circuit with battery voltage monitor should be incorporated for better regulation of the supply voltage.

Further development of this system is to measure actual human ECG signals via electrode chest strap and to investigate more accurate and robust algorithms for R peak detection and R-R interval calculation.

The system is intended to be eventually used in the study of the relation between heart rates, energy expenditures, and intensity levels of aerobic exercises. This is a collaboration research between the Department of Electrical Engineering, Faculty of Engineering, the Department of Pharmacology, Faculty of Medicine, and the Department of Physical Education, Faculty of Education, Khon Kaen University.

V. Conclusion

In this paper, a microcontroller-based system for heart rate monitor is presented. This multi users HRM system is aimed for fitness exercise researches such as the study of relation between heart rate and intensity levels of aerobic exercises. For our application which requires long distance operation, 2.4 GHz RF wireless transceiver modules is chosen for communication between transmitters and receivers. These modules can support multi users up to 125 users which is enough for our purposes.

Test results with an ECG simulator show that both multi users and single user configurations are working as required. From the system effective distance tests, the proposed system works well within the 10 meters indoor range and 100 meters outdoor range.

Acknowledgment

This work is partly supported by the graduate school of Khon Kaen university. Some sample devices are provided from Maxim Integrated Products, Inc.

***Abstract*- Dental restoration is the designed materials used to replace the missing teeth to restore function and morphology. One of the most common types is a bridge, which consists of one or more pontic or artificial teeth anchored by crowns at each end. To fill the gap between the pontic and the crowns, the open space must be bridged to avoid teeth shifting. This bridge is specifically designed for each patient and takes long time to create. Therefore, this paper presents the method for computer aided design using Borland C++ Builder® and OpenGL to connect this open space by 3D object modeling from 3D scanned dental data for design the crowns and bridges. Our technique starts from opening files of the scanned teeth in STL format and selecting the desired surfaces of both end teeth by defining the landmarks and fit them with cubic spline algorithm. Next, the landmarks are rearranged for point matching by comparison of the direction of cross product of the topmost point and the next point on both surfaces. Then the cylinder-like model is created for bridging the space. The bridge can be adjusted size and shape by scaling sections associated with the cubic spline algorithm. The 2D cross section can also be seen using the transformation from 3D frame to 2D contour. The result has shown that our method can be used to create the bridge and leads to the application on adding offset functions, which can be applied for the design of crowns and bridges to fit on individual. This can reduce the production time and also ease to transfer to computer aided production equipment.**

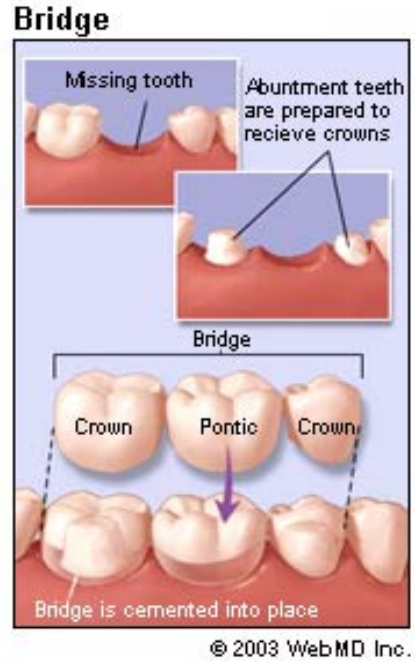

Figure 1 The characteristic of the dental bridge [2]

I. INTRODUCTION

When teeth are missing, the space must be filled to restore the beauty and to avoid several oral complications. The remaining teeth may drift out of position, which causes the change of patient's bite. This change may affect the ability to eat, speak and may produce pain in the jaw joint leading to gum disease or tooth decay [1]. Normally, the methods for tooth restoration are removable denture, bridge and implant. In this paper, the dental bridge is issued due to its reasonable stability, cost, and esthetic. Bridges are nonremovable appliances that are used to replace one or more missing teeth. A typical dental bridge is made up of a pontic (a false tooth) attached to two crowns that cover the surrounding abutment teeth as depicted in Fig. 1. Therefore, the bridge needs the appropriate design to fit on individual. Conventionally, the crowns and bridgework requires the skill and experience of dental technician. It also needs many processes and takes long time to complete. The novel techniques with computer aided design and fabrication have been developed for various dental applications. However, the commercial systems for design crowns and bridgework such as CEREC [3], DentalDesigner™ [4], etc., still have high cost and show no revealed source code. For this reason, the software tool for design the replacement teeth for the bridge application is initially developed in order to help the reduction of the software import to Thailand. In this paper, the focus is on the algorithm used for creating the connector that bridges the gap between each replacement teeth.

II. METHODS

A. Dealing with 3D Model

First of all, 3D tooth model must be imported to the program. Patient's cast model is scanned by the CT scanner and reconstructed into 3D computer model in STL file format which contains surface geometry information of a three

dimensional object. Our software has been written using Borland C++ Builder® and OpenGL to manage this STL model. It also has the user interface for viewing the 3D model with rotation, zoom and translation functions as shown in Fig.2.

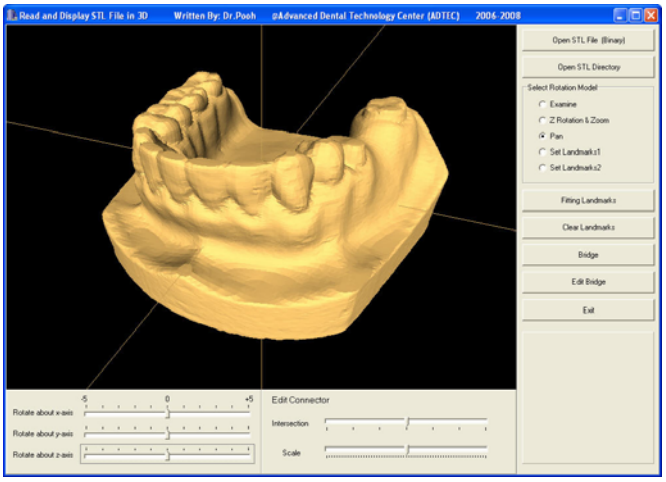

Figure 2 The viewing window of the program

B. Creating Connector

For the bridge part, the suitable standard tooth model is selected to place at the missing tooth, called a pontic. However, there is the gap between the crown and the pontic needed to be connected. Therefore, the algorithm for 3D object connection is performed for bridging them together. First, the desired surfaces for creating the connector of both sides are selected by defining the landmarks with any number of points and the program will fit curve to the circular shape with cubic spline interpolation based on the technique in *Numerical Recipes in C* [5]. One dimensional cubic spline fitting can be explained as in Eq. (1) – Eq.(6). But in our work, some modification has been applied on the interpolation of one dimension to three dimensions. With this method, a series of unique cubic polynomials is fitted between each of the data points with the condition that the curve obtained be continuous and appears smooth. This spline consists of weights attached to a flat surface at the points to be connected. A flexible line is then bent across each of these weights, resulting in a smooth curve. The first step of this approach is applying the three dimensional cubic spline where the one dimensional cubic spline line can be expressed as *G(x)* in Eq. (1) [6, 7].

$$G(x)=\begin{cases} g_1(x) & \text{if} \quad x_1 \le x < x_2 \\ g_2(x) & \text{if} \quad x_2 \le x < x_3 \\ \vdots & \\ g_{n-1}(x) & \text{if} \quad x_{n-1} \le x < x_n \end{cases} \tag{1}$$

where g_i is a 3rd degree polynomial defined by

$$g_i(x)=a_i(x-x_i)^3+b_i(x-x_i)^2+c_i(x-x_i)+d_i \tag{2}$$

for $i = 1, 2, \ldots, n\text{-}1$.

Since the piecewise function $G(x)$ will interpolate all of the data points, we can conclude that

$$G(x_i)=y_i \tag{3}$$

for $i = 1, 2, \ldots, n\text{-}1$. Since $x_i \in [x_i, x_{i+1}]$, $y_i = g_i(x_i)$

The coefficients a_i, b_i, c_i, and d_i in (2) are determined from the first and second derivatives of the n-1 equations of $g_i(x)$. The routine must ensure that $g_i(x), g_i'(x)$ and $g_i''(x)$ are equal at the interior node points for adjacent segments. Substituting a variable S_i for the $g_i''(x_i)$ and y_i for $s_i(x_i)$ will reduce the number of equations and simplify the tasks.

Given the spacing between successive data points is

$$h_i = x_i - x_{i-1} \tag{4}$$

Finally, the variables a_i, b_i, c_i and d_i in (2), or termed the weights of each n-1 equations, will be

$$\begin{aligned} a_i &= \frac{S_{i+1}-S_i}{6h} \\ b_i &= \frac{S_i}{2} \\ c_i &= \frac{y_{i+1}-y_i}{h} - \left(\frac{S_{i+1}+2S_i}{6}\right)h \\ d_i &= y_i \end{aligned} \tag{5}$$

When substituting these weights in (2), its 1st and 2nd derivatives, and including the condition of natural spline where 2nd derivative is equal to zero at the endpoints ($S_1 = Sn = 0$), the system can be determined in matrix equation as follows

$$\begin{bmatrix} 4 & 1 & 0 & \cdots & 0 & 0 & 0 \\ 1 & 4 & 1 & \cdots & 0 & 0 & 0 \\ 0 & 1 & 4 & \cdots & 0 & 0 & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots & \vdots & \vdots \\ 0 & 0 & 0 & \cdots & 4 & 1 & 0 \\ 0 & 0 & 0 & \cdots & 1 & 4 & 1 \\ 0 & 0 & 0 & \cdots & 0 & 1 & 4 \end{bmatrix} \begin{bmatrix} S_2 \\ S_3 \\ S_4 \\ \vdots \\ S_{n-3} \\ S_{n-2} \\ S_{n-1} \end{bmatrix} = \frac{6}{h^2} \begin{bmatrix} y_1 - 2y_2 + y_3 \\ y_2 - 2y_3 + y_4 \\ y_3 - 2y_4 + y_5 \\ \vdots \\ y_{n-4} - 2y_{n-3} + y_{n-2} \\ y_{n-3} - 2y_{n-2} + y_{n-1} \\ y_{n-2} - 2y_{n-1} + y_n \end{bmatrix} \tag{6}$$

Therefore, Eq. (6) is used to find the interpolation values in all dimensions. In this paper, data points can be any number with 10 control points on each segment such that the surface from defined landmarks can be drawn smoothly.

Next, the landmarks on both surfaces are rearranged for point matching by finding the highest point and comparison of the direction of cross product of the topmost point and the next point as illustrated in Fig.3, where $\vec{\mathbf{V}}_1$ is a cross product of $\overrightarrow{\mathbf{O_1A_1}}$ and $\overrightarrow{\mathbf{O_1A_2}}$ and $\vec{\mathbf{V}}_2$ is a cross product of $\overrightarrow{\mathbf{O_2B_1}}$ and $\overrightarrow{\mathbf{O_2B_2}}$. If the result of the dot product between $\vec{\mathbf{V}}_1$ and $\vec{\mathbf{V}}_2$ is

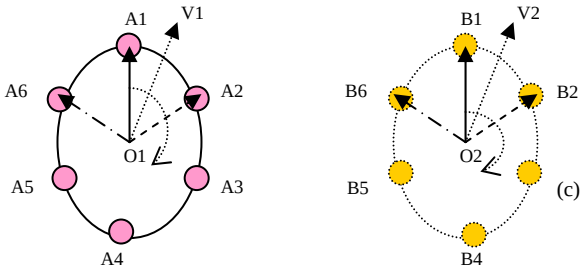

Figure 3 The landmark models from 2 surfaces.
Left, A1-A6 show the landmarks of surface1.
Right, B1-B6 show the landmarks of surface2.

more than zero, the landmarks of two surfaces are arranged in the same direction, otherwise they are reverse. Then the cylinder-like model is created for bridging the space with these arranged points as shown in Fig. 4. To illustrate this model in OpenGL, three points from both surfaces are matched to draw triangular primitive connectedly to form the 3D cylinder. The 3D viewing also involves the lighting that applies on each triangle. An amount of light that object receives at its vertices is determined from the orientation of the normal vector. The normal vector is calculated from the normalized cross products of two vectors on that surface. Due to the flat surface, all three vertices defining a surface share the same normal vector. Therefore, the normal vector needs to be specified only once for each set of three vertices [8].

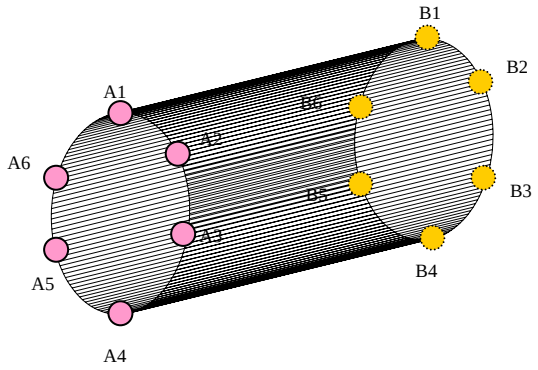

Figure 4 Creating the connector from arranged landmarks.

Moreover, the connector can be adjusted to the most suitable size and shape. The program is able to segment the connector into 1-10 sections by scaling the size of the cylinder according to the user interface. Each section can be scaled its cross section and shown in 2D by the transformation from 3D frame to 2D contour as shown in Fig.5. At first, the 3D positions in world coordinate (F_W) must be transformed to object coordinate (F_O) so that the cross section can be shown perpendicularly on the screen coordinate frame (F_S).

The 3D to 2D projection can be calculated from the generalized equations as the following [9]:

$$S_x = O_x * XSCALE / O_z + X_{Center}, \quad (7)$$
$$S_y = -O_y * YSCALE / O_z + Y_{Center}, \quad (8)$$

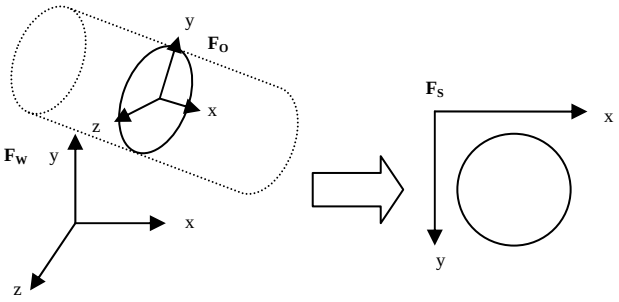

Figure 5 The transformation from world coordinate (F_W) to object coordinate (F_O) and to screen coordinate (F_S).

where S_x and S_y are positions in screen coordinate,
O_x, O_y, and O_z are positions in object coordinates,
XSCALE and *YSCALE* are Field Of View in x and y direction.
X_{Center} and Y_{Center} are half the screen width and half the screen height which are used to correct the alignment because the upper left of the screen is (0, 0). The selected segment is also adjusted at the 2D cross section and affects the size of that segment by inverse transformation.

In addition, the modification in shape in one section also changes curve of the cylinder so that cubic spline interpolation is used again to find three more control points between each segment for smooth the freeform connector.

III. Results

The experiment results with our tooth library have shown that the program can be used to view the 3D tooth model from STL files according to the user interface viewing.

For the 3D tooth connecting section (Fig. 6), user can define the landmarks with any number of point in circular direction (Fig. 6a), and obtain the closed surface, which has to be done

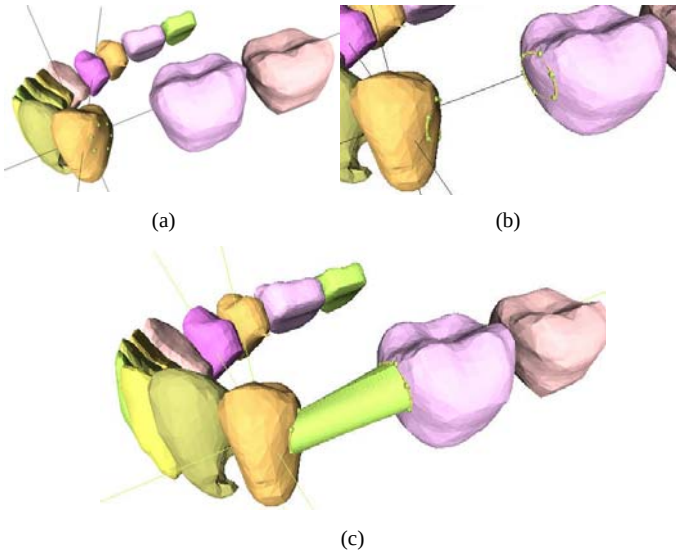

Figure 6 Steps for creating the connector.
(a) Define landmarks, (b) Fit curve on landmarks, and (c) Connect 2 surfaces

on both objects (Fig. 6b). Then 3D connector between 2 objects is generated from these surfaces (Fig. 6c). Moreover, to adjust size and shape of the connector to the most appropriate one, user is allowed to segment the connector and increase or decrease size of that cross section. Without the cubic spline algorithm, each segment was combined directly, which made the adjusted bridge bent sharply as shown in Fig. 7. Therefore, this method was not applied for the design. Alternatively, our program has the cubic spine interpolation step, which can adjust the outer surface of the connector smoothly as can be seen in Fig. 8. The example of the program for connecting two teeth with 10 smoothly adjustable segments is shown in Fig. 9 where the main window illustrates the 3D connector in mesh view and the small window presents the contour of selected section in 2D.

IV. Discussion and Conclusion

The results of the program have expressed that the discussed algorithm can be the basic for the development of the software for the dental bridge design. However, the program still needs further improvements on the 3D measurement and more user friendly on the adjustment functions. Moreover, the dental bridge also consists of the crown parts, which involve the 3D segmentation and offset on the prepared abutments. The integration of these 2 parts has been developing to present the most accurate size, shape, and anatomical features for computer aided design which will be an alternative choice replacing the conventional manual process afterwards.

Adaptive Thresholding for Iris Recognition

Peeranat Thoonsaengngam and Somying Thainimit
Kasetsart Signal and Image Processing Laboratory (KSIP Lab),
Department of Electrical Engineering, Kasetsart University,
50 Phaholyothin Rd. Jatujak, Bangkok, 10900, Thailand

***Abstract*-This paper presents an intensity-based iris recognition system. The system exploits intensity distributions of iris textures. The textures are enhanced and extracted using local histogram equalization and quotient thresholding. This thresholding technique partitions an iris image into regions of foregrounds and backgrounds such that a ratio between these two regions is the same for all iris images in a database. The extracted iris features are encoded in a way to accommodate a fast matching using a table lookup technique. Computational cost of our proposed 1:1 matching is 9 millisecond. The accuracy of the proposed system evaluated using CASIAv.1.0 iris database is 0.001413%EER.**

I. INTRODUCTION

The term 'biometrics' refers to the science and technology of authentication using physiological or behavioral characteristics of human such as fingerprints, signatures, faces, and irises. Among the biometrics, an iris pattern is a highly accurate and reliable characteristic. Flom and Safir [1] reported that the iris patterns are unique to individual and stable over time and across environments (e.g. occupations, humidity ect.). The uniqueness of iris patterns is the product of dense collections of iris structures and textures such as pigment frills, furrows, freckles, and crypts. These textures can be perceived easily. In addition, an iris is a protected organ located behind the cornea, but in front of the lens. This makes personal authentication possibilities life long.

The most successful commercial iris recognition system is a ramification of an algorithm proposed by John Duagman [2]. He uses 2D Gabor filters to extract phase information of an iris. Matching score of two iris codes is evaluated using hamming distance. After his work, several works are introduced. Wildes [3] analyzes iris features using 2-level Laplacian pyramid. Correlation of the obtained images is used to evaluate their similarity. Ma [4] analyzes and extracts iris features using circular symmetry filters. Sun [5] uses zero-crossings of wavelet transform to extract iris features. He represents the features using five geometric moments. Wen Yang [6] suggests using a group of 2D Gabor filters to detect a set of points, named key points. These points represent local iris texture. K. Miyazawa [7] analyzed an iris using 2D DFT. Only the obtained phase components are used to evaluate the match between two irises.

In this paper, we propose an intensity-based iris recognition system. The system aims to extract visible iris textures, which generally have low intensity level. These iris textures are extracted using local histogram equalization and a quotient thresholding [8]. In quotient thresholding, the threshold values for each image in the database are adapted to illumination of the image. Differences between our work and work in [8] are:

- We proposed to use intensity position of the extracted iris features instead of using its shape information. In [8], the extracted features are fitted with various sizes of circles. Diameter of the fitted circle describes the iris features.
- A new and fast matching technique is introduced in this paper. The proposed iris code is encoded to accommodate matching method, also to compensate effects of elastic distortion.
- The proposed method works on an unwrapped iris image, instead of an iris ring. This is to ease matching implementation.

The rest of this paper is organized as follows: section 2 describes our proposed iris recognition. Section 3 illustrates our experimental results and discussions. The last section, section 4 is our conclusion.

II. THE PROPOSED IRIS RECOGNITION

Our iris recognition approach is composed of five main steps: localization, normalization, feature extraction, feature encoding and matching. Their details are described in the following sections.

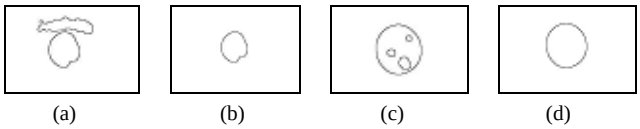
A. Iris Localization

Iris localization is to locate inner and outer boundaries of an iris. The inner boundary of an iris is a boundary separating the iris from the pupil, whereas the outer boundary is a boundary separating the iris from the sclera zone. Both boundaries can be located by exploiting intensity differences among organs (pupil, iris, and sclera) and a prior knowledge of circular-like shape of pupil and iris.

Since intensity level of a pupil is typically low and falls separately from intensity range of other eye components, pupil is detected using thresholding operation. Then, edge detection and edge thinning operations are applied over the thresholded regions. These operations yields edges belong not only to edges of the pupil but also of the other components such as eyelashes and reflected lights as shown in Fig. 1(a) and 1(c), respectively. To obtain only edges belong to the pupil, irrelevant edges are removed by examining its circular and diameter property. Fig. 1(b) and 1(d) shows corresponding results of Fig. 1(a) and 1(c), respectively. The obtained edges are fitted using circular model. The fitting results in two

parameters: r-inner and center, which denoted radius of an iris inner boundary and its center position, respectively. The obtained center position is used as reference point for the rest processes of our recognition system.

The iris outer boundary is detected by exploiting intensity difference between iris and sclera. Contrast enhancement algorithm [9] is applied to the image in order to improve contrast nearby the boundary of iris and sclera. The outer boundary is located by searching for abrupt change of average intensity of pixels along arc defined in Fig.2. The search is started nearby the inner boundary and moving outward. The outer boundary is located where the first abrupt change of the obtained average intensity occurs.



(a) (b) (c) (d)

Figure 1. Example results of pupil detection.

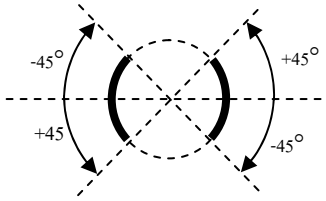


Figure 2. Arcs used in iris outer boundary detection.

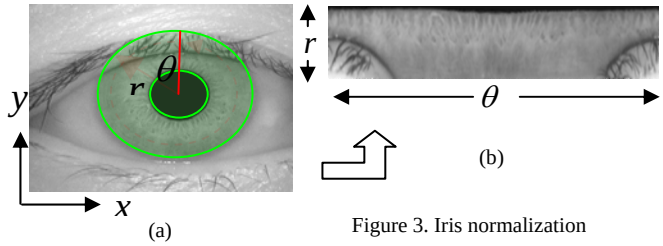
B. *Iris Normalization*

Generally, acquired images of one iris have different iris sizes depending on an amount of incoming light. To compensate this variation, the localized iris is normalized into a fixed size rectangle using (1).

$$r_{input} = \{(i/N)\times(R_{outer} - R_{inner})\} + R_{inner},$$
$$\theta_{input} = (2\pi \times j)/M \qquad (1),$$

where, $(r_{input}, \theta_{input})$ is a polar coordinate of a point (x,y) on an input image as shown in Fig.3(a). R_{inner} is an iris inner boundary. R_{outer} is an iris outer boundary. A point (i,j) is a corresponding point of $(r_{input}, \theta_{input})$ on the rectangle that has a size of $N \times M$. Fig. 3(b) depicts an example result of the conversion.



(a) (b)

Figure 3. Iris normalization

C. *Iris Feature Extraction*

In this paper, iris features are extracted using quotient thresholding (QT) technique. The QT technique is an adaptive thresholding proposed in [8]. The technique aims to extract dark pigmented iris textures such as crypts, freckles and moles. As these textures are visible and generally have low intensity values, thresholding technique can be used to extract these textures. However, thresholding operation is sensitive to image illumination. In order to obtain similar but distinguishable iris features, algorithm in [8] was proposed to compensate non-uniform illumination inhibited within an iris image using local histogram equalization (LHE) and proposed to compensate non-uniform illumination occurred across iris images in a database using quotient thresholding (QT).

The LHE is used not only for compensating non-uniform illumination, but also for enhancing informative iris features. The QT is an adaptive thresholding technique aiming to compensate uneven illumination among iris images. The compensation is done by varying the threshold values resulting in image partitioning, based on its histogram. The threshold value is varied until a ratio between the obtained foregrounds and backgrounds reach a pre-specified value. This value is fixed for all images in a database. By fixing this ratio instead of fixing a threshold value, similar iris patterns could be extracted from images of an iris captured under different lighting conditions.

(d) Four divided parts for QT encoding

Figure 5. Image results from algorithm's progressive

In [8], the described process is applied over a segmented iris ring directly. This paper, we propose to apply the LHE and QT over a normalized iris image instead. This is to facilitate iris feature encoding and matching procedures. In addition noise

reduction using median and mean filters are applied prior the LHE. Fig. 4 shows our proposed feature extraction algorithm. Fig. 5(c) shows a result obtained from applied the proposed feature extraction on a normalized image shown in Fig. 5(a).

As our proposed is an intensity-based method, noises caused from eyelids and eyelashes can significantly degrade our system performance. To reduce this degradation, the proposed algorithm is performed only on area nearby pupil zone as indicated in Fig 5(b). Since eyelashes have very low intensity, they are usually segmented as one part of iris features. To reduce noisy pixels in our iris feature code, we invert the thresholded image before encoding the features. Surrounding pixels of dark iris textures are concerned in our proposed feature encoding and matching algorithm instead.

D. Feature Encoding

Instead of describing the obtained QT feature using its shape properties as in [8], we proposed to describe the QT features using its intensity position. Positions of the obtained foreground pixels, which represent iris features, are used to find the match between two irises. Its matching score is proportional to a number of matched foregrounds.

The encoding process is started from dividing the obtain QT image into 4 sections, indicated in Fig. 5(d). Each section has a size of 64 × 35 pixels. The background pixel is encoded as "0" and the foreground pixel is encoded as "1". For each section, one row of QT image generates a 64-bit QT code. Therefore, one iris image generates a template of 1120 bytes of QT code.

E. Feature Matching

This step is to find similarity of two QT codes. Its similarity is measured by counting a number of matches between foregrounds extracted from two irises. As we encode the foregrounds as "1", counting a number of matched foregrounds is equivalent to counting a total number of "1" resulted from performing AND operation between two QT codes.

Fast implementation of finding a total number of matched foregrounds is accomplished through a table lookup technique. A lookup table, called a matching score array, is created prior. Each cell of the array contains a normalized matching score, which is associated to a number of matched "1" between two binary QT codes. These two codes are row and column index of the cell.

To have a small size array, each row of the QT code, which is 64 bits, is separated into 4 parts. Each part is a 16-bit long. Thus, a matching score array of size 16x16 is used instead of an array of size 64x64.

Rotation and translation invariance can be achieved by shifting each part of the QT code in range of ±17 pixels horizontally and ±10 pixels vertically, independently. The maximum matching score of the shifted QT code represents its matching score. System matching score is a summation of the four best matching scores obtained from the four parts. The proposed method requires 102,900 times to perform AND operations. Therefore, $102{,}900 \times 4 = 411{,}600$ lookups are carried out.

III. EXPERIMENTAL RESULTS

We validated our proposed system using two databases: CASIA v.1.0 [10] and KSIP DB01R iris database [11]. The system performance is measured in term of Equal-Error-Rate (EER), which is equilibrium error of Fault Accept Rate (FAR) and Fault Reject Rate (FRR).

CASIA iris database is a public iris database. The database contains 756 iris images captured from 108 individual eyes, 7 images for each individual. This database requires $7c2 \times 108 = 2{,}268$ comparisons for generating the distribution of the intra-class matching distance and requires $108c2 \times 7^2 = 283{,}112$ comparisons for generating the distribution of the inter-class matching distance.

KSIP DB01R database contains 1920 iris images captured from 120 Thais volunteers. Eight images of their left and right eyes are captured. For this database, $8c2 \times 240 = 6{,}720$ comparisons are required for the distribution of the intra-class matching distance generation and $240c2 \times 8^2 = 1{,}835{,}520$ comparisons are required for inter-class matching distance generation.

TABLE 1
SYSTEM PERFORMANCE OF THE PROPOSED METHOD

QT ratio	CASIA v.1.0	KSIP DB01R
0.05	0.234734	0.818184
0.10	0.003532	0.605192
0.15	0.003355	0.524651
0.20	0.001413	0.484872
0.25	0.007771	0.515969
0.30	0.066726	0.586786
0.35	0.081708	0.657789
0.40	0.094629	0.740491

Our first experiment is finding QT ratio, which yields the best system performance. Table I indicates the obtained EER for each QT ratio. Empirically, the best system performance is obtained when QT ratio equals to 0.20. It yields 0.001413% EER using CASIA database and 0.484872% EER using KSIP database. The distribution of intra-class and inter-class matching distance obtained using the QT method with 0.2 QT ratio is shown in Fig. 6.

It is clearly seen that the proposed QT method is well perform with the CASIA iris database, but not with the KSIP iris database. This is due to inaccurate iris localization and occlusion problems. Irises in KSIP database is more difficult to locate, as pupils in CASIA database are manually filled with black circles and several pupils in KSIP database have their shape closed to an ellipsoid, not a circle. Fitting ellipsoid with circle often includes dark pupil regions within the segmented iris. In addition, KSIP irises are often occluded by eyelashes.

A reason for us to validate our system using CASIA database is that most existing iris recognition system evaluated

their systems using this database. Table II indicates our proposed system performance comparing to existing methods

Computational cost of our proposed system is shown in Table III. Our system is carried out in C++ on PC Pentium IV 2.4 GHz with 512 MB RAM. Matching time of our proposed method is reduced by half when comparing to one in [8], which reported 17 millisecond. for 1:1 matching. Even though, the 1:1 matching time is reduced significantly. The proposed system still needs 9 seconds for 1000 irises comparisons. This timing should be reduced further for large database usage.

IV. CONCLUSION

A new intensity-based iris recognition system is proposed in this paper. Intensity variations of iris textures are enhanced using local histogram equalization and are extracted using an adaptive quotient thresholding. Quotient thresholding partitions an iris image into regions of foreground and background such that a ratio between foregrounds and backgrounds is the same for all iris images in a database. Spatial corresponding between the obtained foreground pixels of the two irises is counted and used to measure its similarity. Effects of elastic distortions of an iris are reduced by partially match the extracted iris features. A system speed is reduced using a table lookup technique for searching for a matching score of two iris codes. Computational time of our proposed 1:1 matching algorithm is 9 msec. The proposed system accuracy is 0.001413%EER using CASIAv.1.0 and 0.484872%EER using KSIP DB01R.

***Abstract*-We propose an on-line signature verification method based on time-frequency characteristics of barycenter trajectory. The barycenter is determined from the center point of signature and two adjacent pen-point positions with respect to time in handwriting process. The time-frequency characteristics of the barycenter trajectory are extracted by expanding the time sequences of velocity and trajectory of the barycenter into wavelet series. Then the corresponding wavelet coefficients are used as the input and output of the FIR(finite impulse response) system characterizing the handwriting motion in handwriting process. The impulse response of the FIR system is used as the individual feature for the particular signature. Finally, signature can be verified by using the K-L expansion of the obtained impulse response. Signature verification experiments are performed on database consisting of 600 signatures. As the results, the average of Type I(false rejection) and Type II(false acceptance) error rates were 2.66% and 1.33%, respectively.**

I. INTRODUCTION

In many countries, signature is the customary way to verify an individual in daily operations such as withdrawing cash from back account and making contract. Visual examination is popular method for signature verification. However, it usually takes long time for operation and there are occasions for the examiners to make some mistakes by the visual examination. In order to verify the signature effectively, an automatic system for signature verification is required. Signature verification is largely classified into two classes. One is off-line method based on only static visual information , the other is on-line method based on dynamics of handwriting process and has a major advantage that it very difficult to forge or copy the dynamics, which are not visible.

Many methods for on-line signature verification or writer recognition have been reported[1]-[8]. In those methods, dynamic features of handwriting have been used such as x, y coordinates of pen-point movement, pen-point velocity and its acceleration. In the work[4][5], the time-frequency characteristics of handwriting process were extracted by using pen-point position in handwriting process. It is considered that using pen-point position directly is not effective to extract the feature of handwriting. We use the barycenter determined from the center point of signature and two adjacent pen-point positions for the feature extraction. In the work[6][7][8], the handwriting feature was extracted by using Fourier approximation of handwriting process. We consider that such a method in [6][7][8] is not enough to extract the feature of handwriting. In this paper, the features of handwriting are extracted by expanding the time sequence of the trajectory and velocity of the barycenter of pen-point movement into wavelet series to extract the time-frequency characteristics of handwriting process. Furthermore, it is considered that the handwriting motion is an individual feature for signature verification. In this paper, the difference between the handwriting motions can be represented by that between FIR systems. Then the FIR system characterizing the handwriting motion is realized by considering the wavelet coefficients of the velocity and trajectory of the barycenter as the input and output of the FIR system, respectively. In order to represent the difference between the handwriting motions, the impulse response of the FIR system is used. Because it can be seen that the FIR system can be completely characterized by its impulse response[9]. In this case, the obtained impulse response is used as an individual feature of a particular signature. Finally, the K-L expansion of the impulse is used to verify signature.

II. PREPROCESSING

It is assumed here that signature is written on a graphical tablet to verify signature. The horizontal and vertical components of pen-point movement at a time, $t = \tau(\equiv t_n)$, in handwriting process are denoted here as $x(t_n)$ and $y(t_n)$, respectively, where τ is a constant sampling rate. In this section, in order to reduce fluctuation of handwriting, three kinds of normalization with respect to the size, location and duration time in handwriting process of signature are performed as follows:

First, in order to make a standard size of signature, the horizontal and vertical components, $x(t_n)$ and $y(t_n)$ are normalized as

$$\hat{p} = \frac{p(t_n) - p_{\min}}{p_{\max} - p_{\min}}, \quad (p = x, y), \tag{1}$$

where $p_{\min} = \min_{0 \le n \le N-1} p(t_n)$, $p_{\max} = \max_{0 \le n \le N-1} p(t_n)$ and N is a total number of sampled points of pen-point position. In the following $p(t_n), (p = x, y)$ are used to represent the normalized components of pen-point position.

Secondly, the location of signature is normalized as

$$c_p = \frac{1}{N}\sum_{n=0}^{N-1} p(t_n), (p = x, y), \quad (2)$$

$$\hat{p}(t_n) = p(t_n) - c_p, (n = 0,1,2,..., N-1), \quad (3)$$

where c_p is the center point of signature.

Thirdly, in order to reduce a fluctuation of pen-point movement in handwriting process, a trajectory of the barycenter determined from the center point of signature and two adjacent pen-point positions with respect to time in handwriting process, is used. The coordinates $r_x(t_n), r_y(t_n)$ of the barycenter are calculated as

$$r_x(t_n) = \frac{\hat{x}(t_n) + \hat{x}(t_{(n+1)})}{3}, r_y(t_n) = \frac{\hat{y}(t_n) + \hat{y}(t_{(n+1)})}{3}. \quad (4)$$

Furthermore, in order to reduce another fluctuation such as duration time in a part of handwriting process, a segmentation of handwriting process is performed. The pen-up signal is used as the segmentation point for separating a signature trace into a set of components strokes. Then in order to represent the handwriting process for each stroke, we define the followings

$$z_i(t_n) = r_x^{(i)}(t_n) + j r_y^{(i)}(t_n), \quad (5)$$

$$v_i(t_n) = z_i(t_{(n+1)}) - z_i(t_n), j = \sqrt{-1}, \ (i = 1,2,..., L), \quad (6)$$

where $z_i(t_n)$ represents barycenter trajectory and $v_i(t_n)$ corresponds to an average of the velocity between the two adjacent barycenter, L is the total number of stroke in a handwriting process after segmentation. In order to normalize the duration time in the part of handwriting process a piecewise-linear function(PLF) of $z_i(t_n)$ and $v_i(t_n)$ are determined by connecting their components with a straight line. The PLF can be described as

$$q(t) = \sum_{n=0}^{N} q(t_n)\phi_n(t), \ (q = z_i, v_i), \ t \in T_i, \quad (7)$$

where

$$\phi_n(t) = \begin{cases} \dfrac{t - t_{(n-1)}}{t_n - t_{(n-1)}}, t \in [t_{(n-1)}, t_n] \\ \dfrac{t_{(n+1)} - t}{t_{(n+1)} - t_n}, t \in [t_n, t_{(n+1)}] \\ 0, t \notin [t_{(n-1)}, t_{(n+1)}] \end{cases}$$

and T_i is the duration time in the i-th part of handwriting process. Using (7), the duration time in the i-th part of handwriting process is normalized as T_i^N . The T_i^N is determined by using training data for a particular signature.

III. FEATURE EXTRACION

In this section, in order to extract the time-frequency characteristics of the handwriting process, the $z_i(t_n)$ and $v_i(t_n)$ obtained in the preceding section are expanded into wavelet series as

$$q(t) = \sum_{l=0}^{M}\sum_{k=0}^{2^M-1} a_{l,k}^{(q)}\psi_{l,k}(t), \quad (q = z_i, v_i), \quad (8)$$

where $\psi_{l,k}(t)$ is orthonormal wavelet:

$$\psi_{l,k}(t) = 2^{l/2}\psi(2^l t - k), \quad l, k \in Z, \quad (9)$$

$$< \psi_{l,k}, \psi_{m,n} > \equiv \int_{-\infty}^{\infty} \psi_{l,k}(t)\psi_{m,n}(t)dt = \delta_{l,m}\delta_{k,n}, \quad (10)$$

where Haar function is used as mother wavelet $\psi_{l,k}(t)$, $\delta_{l,p}$ is Kronecker' delta and $a_{l,k}^{(q)}, (q = z_i, v_i)$ is the wavelet coefficients obtained through the inner product $a_{l,k}^{q} =< q, \psi_{l,k} >$ as shown in Fig. 1.

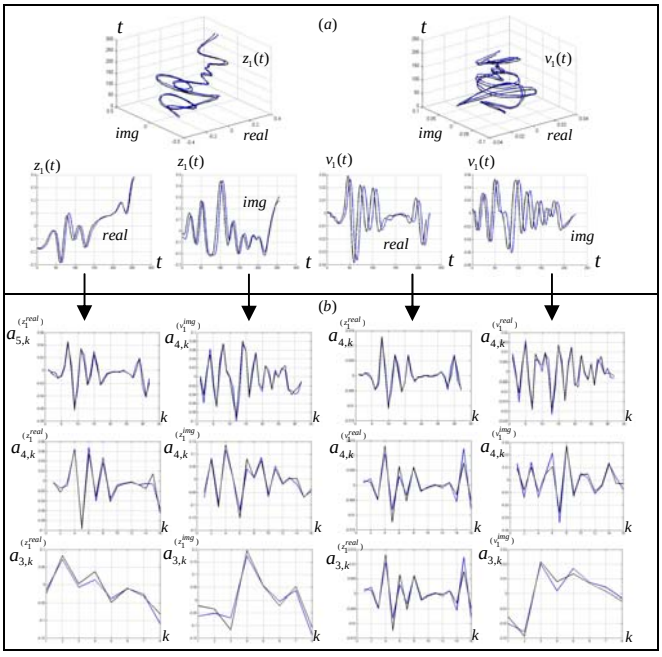

Figure 1. Z_i, V_i and their wavelet coefficients

For the simplicity of explanation, we define the following functions.

$$a_{M,k}^{(q)} = a_{M,k}^{(q^{(real)})} + j a_{M,k}^{(q^{(img)})}, (q = z_i, v_i), \quad (11)$$

$$\boldsymbol{a}_{\boldsymbol{M}}^{(\boldsymbol{q})} = [a_{M,1}^{(q)}, a_{M,2}^{(q)}, ..., a_{M,2^{M-1}}^{(q)}]', \quad (12)$$

$$\boldsymbol{f}_i = [\boldsymbol{a}_1^{(v_i)}', \ \boldsymbol{a}_2^{(v_i)}', ..., \boldsymbol{a}_M^{(v_i)}']' = [f_i(1), f_i(2), ..., f(\underline{N})]', \quad (13)$$

$$\boldsymbol{g}_i = [\boldsymbol{a}_1^{(z_i)}', \ \boldsymbol{a}_2^{(z_i)}', ..., \boldsymbol{a}_M^{(z_i)}']' = [g_i(1), g_i(2), ..., g(\underline{N})]', \quad (14)$$

where $a_{M,k}^{(q)}$ is wavelet coefficient, $\underline{N}$ is a total number of element in $\boldsymbol{f}_i$ and $\boldsymbol{g}_i$, $[.]'$ means the transposition. We consider a handwriting system characterizing the handwriting motion in the handwriting process. The handwriting system consists of subsystem describing the dynamic features in the corresponding part of handwriting process. The subsystem is realized by considering the wavelet coefficients $f_i(k)$ and $g_i(k)$ as the input and output of the i-th subsystem,

respectively. Fig. 2 shows the FIR system characterizing the handwriting system.

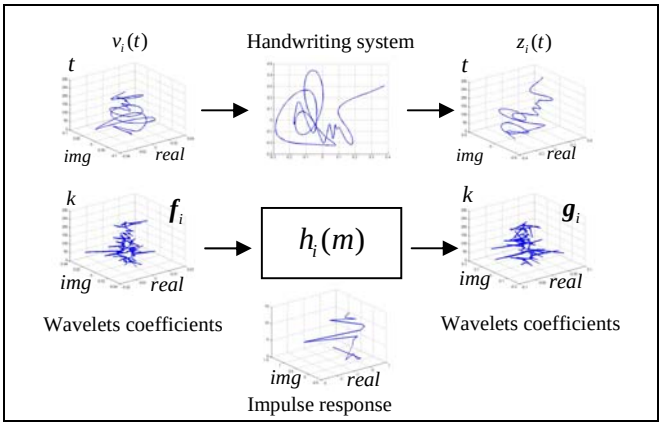

Figure 2. FIR system characterizing the handwriting system.

It is assumed that the subsystem can be described by

$$\hat{g}_i(k) = \sum_{m=0}^{M_i} h_i(m)\, f_i(k-m), (k = 0,1,...,K_i - 1), \quad (15)$$

where $\boldsymbol{h}_i' = [h_i(0), h_i(1), .., h_i(M_i)]$ is an impulse response of the subsystem, M_i is the order of the subsystem and $\hat{g}_i(k;\boldsymbol{h}_i)$ is an approximation of $g_i(k)$. $\boldsymbol{h}_i'$ means the transposition of $\boldsymbol{h}_i$. The impulse response $\boldsymbol{h}_i$ can be obtained by minimizing the least-square error at M_i as

$$E_i = \sum_{k=0}^{K_i-1} \left| g_i(k) - \hat{g}_i(k;\boldsymbol{h}_i) \right|^2 \to \min. \quad (16)$$

The details to determine the impulse response are reported in the work[7]. In order to characterize the handwriting motion in a whole handwriting process, the impulse responses of subsystems are combined as

$$\boldsymbol{h}^{\#} = [\boldsymbol{h}_1', \boldsymbol{h}_2', \boldsymbol{h}_3', ..., \boldsymbol{h}_L']', \quad (17)$$

where $\boldsymbol{h}^{\#}$ is a feature parameter vector used as the feature of handwriting. Fig. 3 shows the impulse response of the FIR system obtained from genuine signature and forgery. It can be seen from Fig. 3 that the impulse responses of the FIR system obtained from genuine signatures are quite similar and different from that obtained from the forgeries. Therefore it is considered that the obtained impulse response can be used as the individual feature of the particular signature.

IV. Signature Verification

In this section, the K-L expansion of the feature parameter vector obtained in the preceding section is used to verify signature. The signature verification procedures are given below.

1) Calculate the following covariance matrix R:

$$R = \frac{1}{P}\sum_{i=1}^{P} (\tilde{\boldsymbol{h}}_i^{\#} \tilde{\boldsymbol{h}}_i^{\#\prime}), \quad (\tilde{\boldsymbol{h}}_i^{\#} = \boldsymbol{h}_i^{\#} - \bar{\boldsymbol{h}}^{\#}), \quad (18)$$

$$\bar{\boldsymbol{h}}^{\#} = \frac{1}{P}\sum_{i=1}^{P} \boldsymbol{h}_i^{\#}, \quad (19)$$

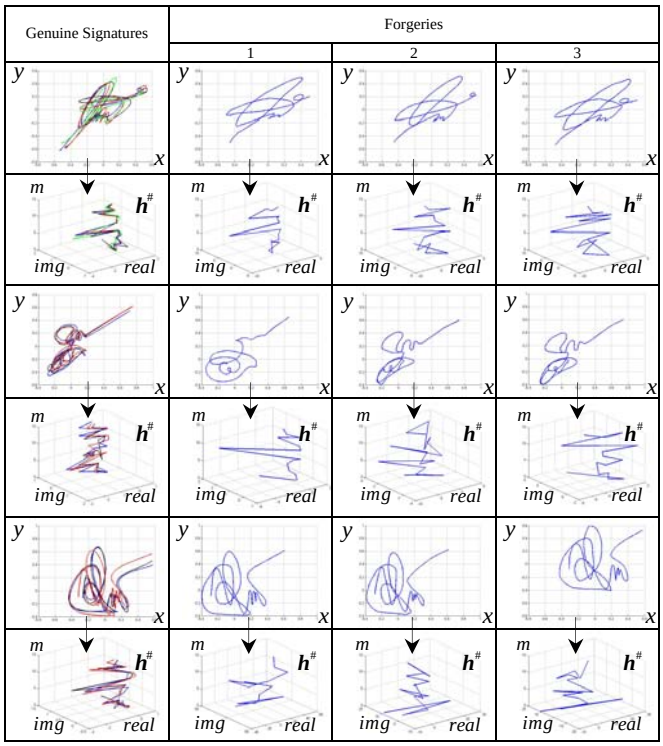

Figure 3. Impulse response obtained from genuine signatures and forgeries.

where $\boldsymbol{h}_i^{\#}$ is the feature parameter vector obtained from training data for the particular signature, P is a total number of training data.

2) Calculate the eigenvalues λ_k and the corresponding eigenvectors $\boldsymbol{u}_k$ of the covariance matrix R:

$$R\boldsymbol{u}_k = \lambda_k \boldsymbol{u}_k. \quad (20)$$

3) Form the transformation matrix U from the N^* eigenvectors corresponding to the largest eigenvalues of R as follows

$$U = [\boldsymbol{u}_1, \boldsymbol{u}_2, ..., \boldsymbol{u}_{N^*}] \quad (21)$$

where

$$\lambda_1 > \lambda_2 > ... > \lambda_{N^*}.$$

4) Compute the K-L coefficients $\boldsymbol{c}$

$$\boldsymbol{c} = U'\,\tilde{\boldsymbol{h}}^{\dagger} \equiv [c_1, c_2, ..., c_{N^*}], \quad \tilde{\boldsymbol{h}}^{\dagger} = \boldsymbol{h}^{\dagger} - \bar{\boldsymbol{h}}^{\#}, \quad (22)$$

where $\boldsymbol{h}^{\dagger}$ is the feature parameter vector obtained from the signature to be verified and $\bar{\boldsymbol{h}}^{\#}$ is obtained from (19).

5) The signature is verified as

$$\begin{array}{ll} \text{True} & \text{if } \|\boldsymbol{c}\| < \eta, \\ \text{False} & \text{otherwise,} \end{array} \quad (23)$$

where $\|\,.\,\|$ is Euclidean norm and η is a predetermined threshold value determined using training data set for a particular signature

V. EXPERIMENTS

Signature verification experiments were performed on database consisting of 300 genuine signatures and 300 forgeries collected from 10 particular writers for one year. In the experiments, the training data set of the feature parameter vectors was determined using 4 signatures selected randomly from the database for a particular signature. Fig. 5 shows the examples of Euclidean distance obtained from (23) using the signatures in our database. In the experiments, we use the threshold value at the point where the two types of error rates are nearly equal for a particular signature. Comparison of the experimental results for the proposed method and the method in the work[8] were shown in Table I. It can be seen in Table I that the proposed method is able to verify signature with better error rates in comparison with the work[8]. Fig. 4 shows the comparison of the impulse responses obtained from the proposed method and method in the work[8]. It can be seen from Fig. 4 that the impulse response obtained from the method in this paper is more suitable for signature verification than that obtained by using method in the work[8].

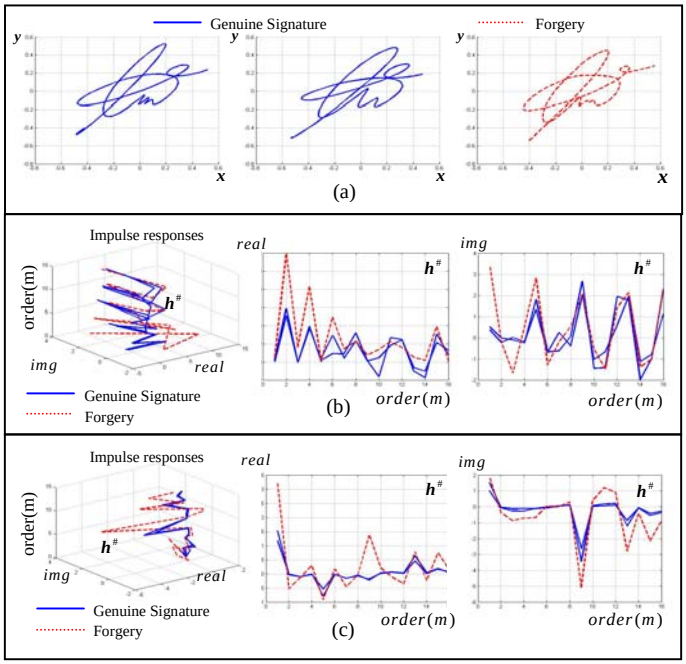

Figure 4 . (a) Genuine signatures and forgery, (b) impulse response (method in the work[8]) , (c) impulse response (the proposed method).

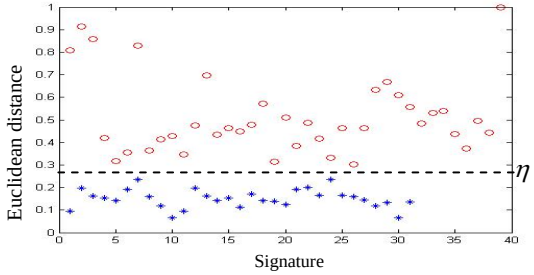

Figure5. Euclidean distances

TABLE I ERROR RATES

Persons	Number of data		Error rates (%) (proposed method)		Error rates (%) (method in work[8])

VI. CONCLUSIONS

We proposed an on-line signature verification method based on time-frequency characteristics of barycenter trajectory of pen tip in signing process. In the proposed method. Haar wavelet was used to describe the above time-frequency characteristics. In order to extract the individual signing feature for a particular person, the wavelet coefficients of the velocity and the barycenter trajectory in signing process were used as the input and output of a FIR system characterizing the signing process. Then the impulse responses of the FIR system were defined as the individual signing feature. Signature verifications were performed by evaluating the difference between the impulse responses for genuine signature and forgery. It was found from our experimental results that the impulse responses can characterize the individual signing feature clearly and available for signature verification.

***Abstract*- This paper presents a signature identification using linear prediction code (LPC) coefficients and Neural Network. The 2-D signature signal obtained from the tablet digitizer is separated into two 1-D signals. Each signal represents the information in horizontal and vertical direction versus time, (X,T) and (Y,T) respectively. These signals are modeled by the linear prediction system where the LPC coefficients represent the extracted features. The obtained feature vectors are fed as the input to the neural network for training and verification. The test results show that the average accuracy achieves 98.33% when using only either the (X,T) or the (Y,T) signals and 87.67% accuracy when using both of them to verify owner signature. In addition, for fraudulent situation, the proposed system provides 45% and 84% of accurate verification when inspecting either the (X,T) or the (Y,T) signals and both of signals, respectively.**

I. INTRODUCTION

Nowadays, there are many methods to identify person. Especially, the method of biometric which makes use of biology characteristic of each person such as, fingerprint, eye's pattern and ECG (Electro Cardiogram) to identify the uniqueness of human. However, a conventional way such as personal signature is still be the most popular one. For example, in banking system, the signature is employed to identify the owner of banking account. Another example is in an e-passport system; even though the biometric information such as fingerprint is an addition requirement but the conventional signature is remain used.

As stated above, personal signature which is handwriting of each person thus still be important. It is a simple, and a low cost technique which provides a high accuracy of identification. Conventionally, the decision of signature verification is done by a human (e.g. a bank teller); however, this task would be more convenient if it can be accomplished by an automated system.

In literature, the signature personal verification systems are classified into two methods, the first one is an off-line (statistical) technique and the second one is an on-line (dynamic) technique [1-11]. For the off-line technique, a 2-D image X-Y plane or horizontal and vertical data of signatures is collected and compared with image of owner signature that is previously collected. But this technique is easily fraudulent because the dynamic feature of the signature is not taken to be accounted. Therefore, the on-line technique is an alternative method. The data (X, Y, T) of a signature are collected where (X, Y) is a co-ordinate of each data point and T represents time at that point, respectively. For dynamic system (on-line), both similarity and stroke of the obtained signature are simultaneously used for personal verification. As a result, it is very difficult for one who attempts to fraud the signature without stoke information. Hence, most employed personal identification systems are based on dynamic handwritten technique.

In general, the dynamic method colleted signature signals with a tablet digitizer. The obtained signals are preprocessed (such as magnitude normalization, time normalization and DC canceling) by microprocessor and then discriminated their features for example velocity, and/or accelerate of signature signal [1],[3], or pressure, variation, vibration and consistency [2]. These features are then fed to be input of a decision process such as Hidden Markov Model, NNW (Neural Network) [12].

In this paper, the dynamic signature verification system is proposed where the handwritten feature extraction is based on linear predictive coding (LPC). The 2-D signature signal collected by a tablet is arranged into two of 1-D signals which are a (X, T) signal and a (Y, T) signal. The two groups of the LPC coefficients respectively obtained from a (X, T) signal and a (Y, T) signal are fed to be the input of a perceptron learning rule neural network for training and/or making a decision of signature verification.

The organization of this paper is given as follows. In section 2, the proposed handwritten identification system and preprocessing detail are described. The results are presented in section 3 where the conclusion and future work are summarized in section 4.

II. THE SIGNATURE IDENTIFICATION SYSTEM

In this work, the signature verification system is presented which is shown in Fig.1. As can be seen, the system is composed of three important procedures; the first one is the preprocessing such as time and magnitude normalization and DC filtering. For the second one, it is the feature extraction process. The LPC coefficients of each signal are determined in the last procedure. Finally, features of the signature signal in the form of LPC coefficients are kept for reference and/or verified.

A. Pre-processing

The 2-D signature signal obtained from the tablet (as an example shown in Fig. 2) is divided into two 1-D signals. These signals which are the (X,T) and the (Y,T) signals

representing information of the signature signal in horizontal and vertical direction, respectively.

Both 1-D signals are DC rejected by subtracting its mean value. In addition, they are normalized to have magnitude scale between -1 and 1 and time scale between 0 and 1000. The preprocessed version of the horizontal signal (X,T) and the vertical signal (Y,T) are illustrated in Fig. 3 (a) and (b), respectively.

B. LPC coefficients

Linear prediction is well-known to be a method for signal source modelling. It is not only dominant in speech signal processing but also wide-spread applied in other areas. The detail of linear prediction will be briefly reviewed as follows.

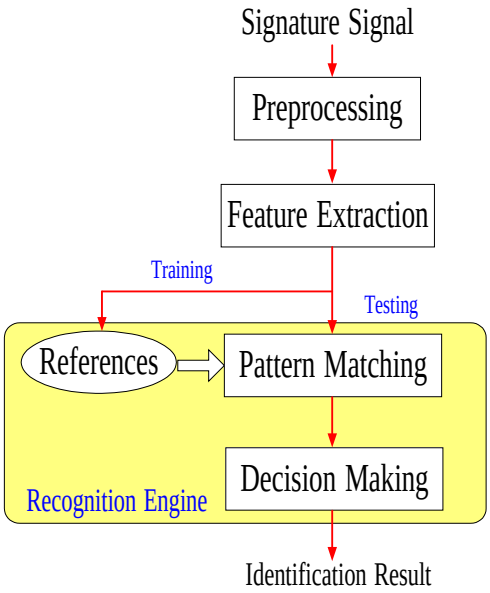

Figure 1. The procedures of the proposed signature verification system.

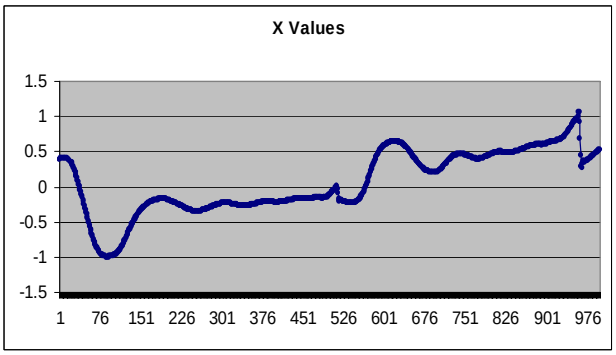
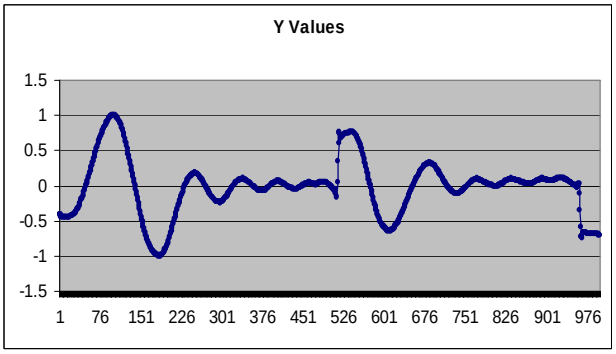
Figure 2. Example of test signature.

The objective of linear prediction is to form a model of a linear time-invariant digital system through the observation of input and output sequences. In other words, it attempts to estimate a set of coefficients which best describe the behaviour of an LTI system.



(a)



(b)

Figure 3. The preprocessed version of the signature signal
(a) The horizontal signal
(b) The vertical signal

Particularly, linear prediction determines a set of coefficients which provide *a prediction* for a forthcoming output sample $y'[n]$ given knowledge of previous input ($x[n]$) and/or output ($y[n]$) samples. This prediction can be expressed as the following difference equation

$$y'[n]=\sum_{k=0}^{p} a_k x[n-k]-\sum_{k=1}^{q} b_k y[n-k] \quad (1)$$

where a_k and b_k are *predictor coefficients*. It is noted that this estimator provides an inherent sensible way to model its properties even though the order of the system has not known in advance. In general, the most common form of linear prediction used in signal processing is one which the b_k coefficients are zero, so that the output estimate is made entirely on the basis of previous output samples, namely

$$y'[n]=-\sum_{k=1}^{q} b_k y[n-k] \quad (2)$$

which is called an *all-pole* model.

By using the relationship shown in (2), q is equal to order of coefficients, the resulted LPC coefficients of the pre-processed horizontal signature signal (X,T) and the pre-processed vertical signature signal are illustrated in Fig. 4(a) and (b), respectively.

C. *Artificial Neural Network*

An artificial neural network (ANN) is a mathematical structure which is designed for mimic information processing. The structure may have one neuron or multilayer perceptrons. For a one-neuron structure, the network is composed of a set of connected neuron. The neuron receives information through a number of input nodes and then internally processes it to produce a response. An example of a single layer perceptron network with four input nodes is demonstrated in Fig. 5. The process of neural network is typically divided into two stages. The first stage is a linear combination of inputs which is

$$w_{i1}x_1 + w_{i2}x_2 + w_{i3}x_3 + \mathrm{L} + w_{im}x_m$$

which w_{im} and x_i are weight and input vector, respectively. The obtained a linear combination of inputs is then used as the argument of a nonlinear activation function, $Y = f(V)$ which each output node is given by

$$y_i = g\left(\sum_{j=1}^{N} w_{ij}x_j - \mu_i\right) \qquad (3)$$

where

w_{ij} : Connection weight of branch *(i,j)*

x_j : Input data from node *j* in the input layer

μ_i : Threshold value of node *i* in the output layer

g : Activation function

N : Number of input nodes.

III. Simulation Results

In this section, the proposed procedures given in Fig. 1 are examined where one-hundred signature signals obtained from 20 persons (5 signatures from each person) are employed. As can be seen in Table I, by inspecting either the horizontal signature signal (X,T) or the vertical signature signal (Y,T), the results show that the proposed verification system can correctly identify signature 100% of accuracy for q = 10 and 20 and 95% for q = 30. For the case of using both signals ((X,T) and (Y,T) signals) in the inspecting process, the tested results provide 95% for q = 10, 90% for q = 20 and 78% for q = 30.

In addition, two situations of fraudulent signature which are the case that stroke, timing and sequence of the tested signature are unknown and known, respectively, are examined. The fraudulent signatures of these cases are forged by other 5 persons (5 signatures/person/case). The tested results of these situations where q = 10, 20 and 30 are given in Table II – IV, respectively. For the first case, the test results show 64% of accurate verification for q = 10, 20 and 30 when inspecting only the horizontal (X,T) or vertical (Y,T) signals and 88% of accuracy when inspecting both directions of signal for q = 10, 20 and 30. In the second case when stroke, timing and sequence of the signature are known, the test results show that the accurate verification decreases to 24% for q = 10, 26% for q = 20 and 28% for q = 30 when inspecting only the horizontal (X,T) or vertical (Y,T) signals. In addition, when inspecting both horizontal (X,T) or vertical (Y,T), the accuracy decreases to 80% for q =10, 20 and 30.

TEST RESULTS FOR FRADULENT SIGNATURE (q = 30)

Fraudulent signatures	Percentage of accurate verification	
	Inspecting in the (X,T) or the (Y,T) signals	Inspecting both the (X,T) and the(Y,T) signals
Unknown stroke, timing and sequence	64	88
Known stroke, timing and sequence	32	80

IV. SUMMARY

In this paper, the signature verification system based on LPC coefficients is proposed. The information of the signature signal in horizontal direction and vertical direction (both are respected to time), respectively, (X,T) and (Y,T) are feature extracted by using LPC technique. The obtained LPC coefficients are fed to be the input of the ANN for verification. For owner signature verification, the test results show 98.33% of accuracy in average when either the (X,T) or the (Y,T) signals are inspected. But it provides averagely 87.67% of accurate verification when both of the (X,T) and the (Y,T) signals are inspected. For the fraudulent situation, the percentage of accuracy decreases to averagely 45% when either the (X,T) or the (Y,T) signals are inspected and to averagely 84% when both of the (X,T) and the (Y,T) signals are verified. For the future research, the number of LPC coefficients that is suitable for this system is further studied. Additionally, more signature signals are verified to prove accuracy of the proposed system in practical.

***Abstract*- The problem of signature verification is a pattern recognition task used to discriminate two classes, genuine and forgery signature. In this paper, we propose on-line signature verification using n-tuple learning machine developed on entropy method. The n-tuple networks have predominantly been used as fast pattern classification and generalization ability, make the signature verification system particularly powerful that when verifying skilled forgeries. To increase the generalization ability of the network, we optimized the network synapses by the entropy estimation of all data that are trained to the n-tuple. Some network inputs will be connected to positions of the data that give the high entropy. In this work, we trained all parameters as binary patterns to the network. The results show the total error rate(TER) at 3%.**

I. INTRODUCTION

Personal identity verification has a great variety of applications including access to computer terminals, buildings, credit card verification. Algorithms for personal identity verification can be roughly classified into four categories[1] depending on physical/behavior and biometric/object as shown in figure 1.

Visual examination is the most popular approach for signature verification, yet there are many occasions for the examiners to make mistakes or lower their thresholds of acceptance. For instance, a previously written signature signed on the back of a credit card in a commercial transaction is more or less a challenge to the clerks. As a result, large financial losses may occur. It is clear that signature verification through visual examination can only judge the authentication roughly. Without expertise, human eyes can hardly analyze the detailed writing features. So there is a need for the machine to do this job instead.

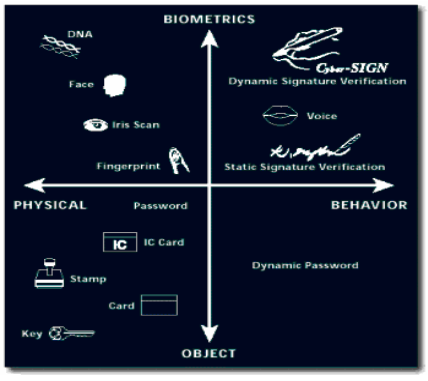

Figure 1. Personal identity verification.

Signature verification can be performed through the machine on-line or off-line. These two approaches and several other practical aspects related to the more general theme of handwriting recognition are discussed at length in the survey from Plamondon[2]. On-line signature verification methods can be further divided into two groups[2], direct methods (using the raw function of time) and indirect methods (using parameters). In the first case, the signature is stored as a discrete function to be compared to the standard from the same writer, that is previously computed during an enrolment stage. Such methods simplify data acquisition but the comparison process can become a hard task. On the other hand, the indirect methods require a lot of effort in preparing data to be processed, but the comparison process is quite simple and efficient. We used the later one with on-line signature verification.

In the rest of the paper, we describe the data acquisition in section 2, the pre-processing in section 3. The connection optimization is explained in section 4. The model of n-tuple used in this work is described in section 5. Experiments and results are shown in section 6. Finally, section 7 provides the conclusion.

II. DATA ACQUISITION

To acquire data in the dynamic verification system, we used a digital tablet, capturing dynamic information of signatures such as x-y position, pressure of pen and altitude of each sampling period as shown in figure 2. In this system, we use a WACOM Intuos size 12x12 inches.

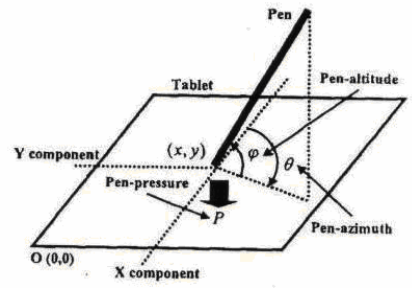

Figure 2. Parameters of the on-line signature.

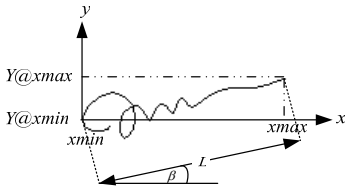

Figure 3. The angle between 0 to 45 degree

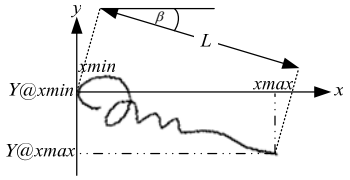

Figure 4. The angle between -45 to 0 degree

III. PREPROCESSING

Generally the preprocessing of signature verification includes the normalization of rotation, scaling, sampling points and binary image conversion, as follows.

A. *Rotation*

Set the angle of each signature to the most extensive.

Case I : the angle between 0 to 45 degree as shown in figure 3 ($Y@x\max - Y@x\min$ is positive).

$$L = X\max\cos\beta + Y@x\max\sin\beta \quad (1)$$

where β beginning with 0 increasing until 45 degree cause; L being maximum value. The signature is then rotated by (2) and (3).

$$X^*(t) = x(t)\cos\beta + y(t)\sin\beta \quad (2)$$

$$Y^*(t) = y(t)\cos\beta - x(t)\sin\beta \quad (3)$$

where $X^*(t)$ and $Y^*(t)$ are the positions of the signature data after rotation and β is the stable angle of signature obtained from (1).

Case II : the angle between -45 to 0 degree as shown in figure 4 ($Y@x\max - Y@x\min$ is negative).

$$L = X\max\cos\beta - Y@x\max\sin\beta \quad (4)$$

where β gives the maximum value of L. Then, the signature is rotated by (5) and (6).

$$X^*(t) = x(t)\cos\beta - y(t)\sin\beta \quad (5)$$

$$Y^*(t) = y(t)\cos\beta + x(t)\sin\beta \quad (6)$$

B. *Scaling*

Set the sizes of each signature to 10 cm on x-axis and 5 cm on y-axis.

$$x^*(t) = \frac{x(t) - x\min}{x\max - x\min} \times sizex \quad (7)$$

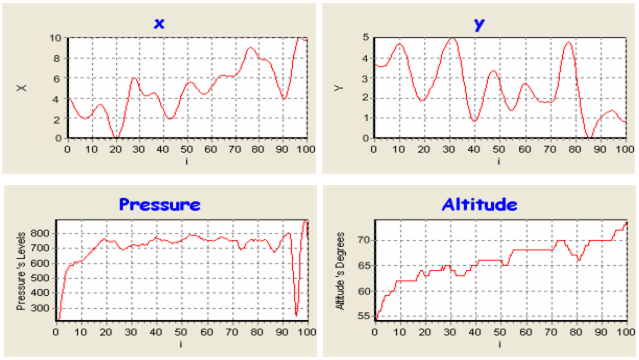

Figure 5. Images of all data after rotation and scaling

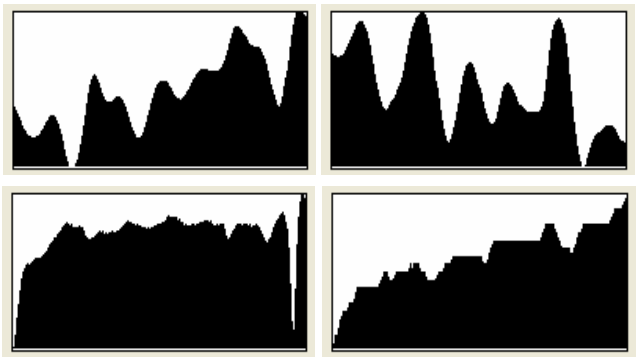

Figure 6. Binary images of all data

$$y^*(t) = \frac{y(t) - y\min}{y\max - y\min} \times sizey \quad (8)$$

where *sizex* and *sizey* are the sizes of signature on x-axis and y-axis respectively.

C. *Sample points*

Resampling 100 points from the individual x position, y position, pressure and altitude respectively.

D. *Binary image conversion*

Convert all feature graphs to binary image files namely bitmap of 200 x 100 pixels as shown in figure 6.

IV. CONNECTION OPTIMIZATION

The merit of n-tuple machine is the use of smaller number of connection by partially connected to the input field, which cause to increase the generalization ability.

Recently, the methods of network feature optimization in signature verification by used genetic algorithm(GA) has been proposed by[3]. The genetic algorithm is based on natural selection, the process drives biological evolution through inheritance, mutation, selection and recombination.In this work, we used entropy method to optimize the best horizontal input connected to the network.

Entropy Theory

The concept of Shannon's entropy[4][5] is the central role of information theory sometimes referred as measure of

uncertainty. The entropy of a random variable is defined in terms of its probability distribution[4] and can be shown to be a good measure of randomness or uncertainty.

The uncertainty is associated with the required amount of data so it can also be thought of as an information measure or quantifier. The value that quantifies uncertainty originally related to random variables which take different probabilities among a set of states. Shannon's entropy has become a very useful way of evaluating structure and pattern in the data.

To optimize the number of horizontal connections, the entropy is used by computing the probability distribution of data for each column of the input field from

$$P_{ij} = \frac{E_{ij}}{E_i} \tag{9}$$

where P_{ij} is the probability distribution at the sample point *i* pattern *j*. E_{ij} is the data at the sample point *i* pattern *j*. E_i is all data at the sample point *i*. The entropy (*H*) is defined in (10) and shown in figure 7.

$$H = -\sum_{j=1}^{n} P_{ij} \ln P_{ij} \tag{10}$$

where *n* is the number of patterns.

The columns of the input field that give the highest entropy will be connected to the network.

V. VERIFICATION PROCESS

Conventional n-tuple systems[6][7] have the desirable features of super-fast single-pass training, super-fast recognition and conceptual simplicity. In n-tuple machines, the basic model of a neuron is a standard Random Access Memory(RAM).

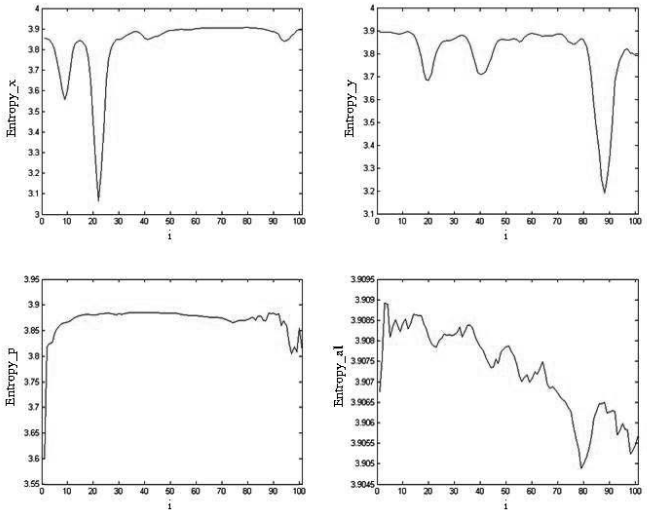

Figure 7. The entropy of all training data

The inputs to the neuron are binary values, which are used to form an address to the RAMs, while the output of the neuron is the data value stored at this address. By this configuration, the n-tuple network will have ability to generalization. The n-tuple is composed of a single layer feed forward as shown in figure 8.

In the training phase, all RAM locations are initially cleared or in undefined-state(u-state) as shown in figure 9. Training the n-tuple network is a single-pass process in which each discriminator is trained individually on a set of patterns as content addressable memory[8]. During the training all the sets of discriminator, which are addressed by the training parameters of the pattern, are set to 1. The process is repeated until all patterns of the training data are trained.

Testing the n-tuple network is performed by presenting an unknown pattern to network inputs. The Hamming distance(HM) proposed by Allinson and Kolcz[9] is used to measure the difference between the unknown binary bit strings and the stored memory. The address that gives the nearest in HM will fire the output.

Thresholding

The outputs of all nodes firing are collected. If the number of output nodes is greater than the preset value, the unknown image is approved, otherwise rejected. The threshold is the value under surface of standard normal score graph as shown in figure 10, we used 95% (-2 < z < 2)[10]. The threshold values are computed as

$$TH = \overline{X} + (Z \times SD) \tag{11}$$

where *TH* is the threshold value, $\overline{X}$ and *SD* are mean and standard derivation of the genuine signature scores.

Figure 9 Training phase of the n-tuple

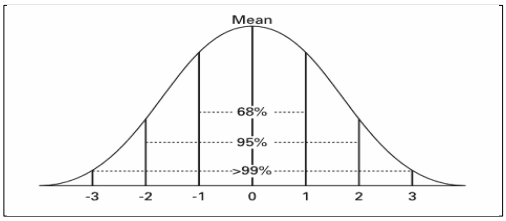

Figure 10. Standard score graph

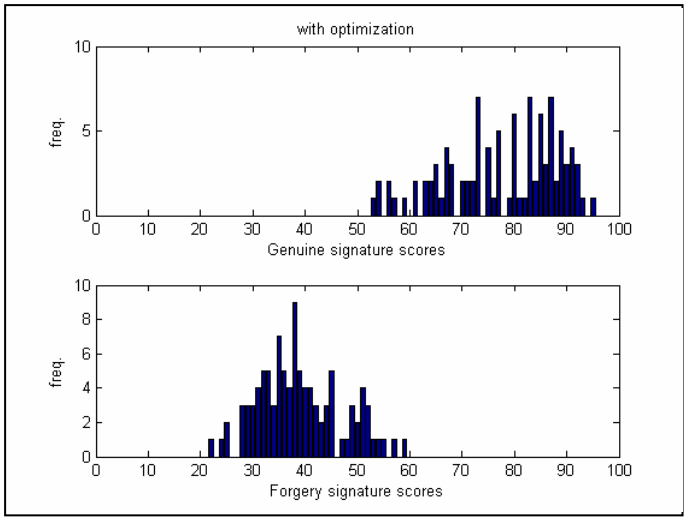

Figure 11. Scores of all testing data with optimization

VI. Experiments and Results

In the experimental, the database consists of totally 300 signatures, with 200 genuine signatures and 100 forgeries from five forgers. We use 100 genuine signatures to train the n-tuple and 100 genuine signatures and 100 forgeries for testing.

The n-tuple contains 100 tuples with 10 fan-ins each. Each tuple has 1 score, there for, the network has maximum 100 scores

In this paper, the higher entropy positions are connected to some synapses and a few number of synapses for lower entropy connections. From the experiment, the scores of all testing data with and without optimization are shown in figure 11 and 12 respectively, which the scores without optimization have large overlapped area than the optimization. As a result, the genuine signatures score have $\overline{X}$ = 77.6, SD = 10.7 and TH = 56. The system give the total error rate(TER) 3 %, false acceptance rate(FAR) 3 % and false rejection rate(FRR) 3 %.

VII. Conclusions

On-line signature verification using n-tuple has been proposed in this paper. The n-tuple networks have predominantly an ability of fast pattern classification and generalization. To increase the generalization, we optimized the network synapses by using the entropy technique, some of the network inputs will be connected to the positions of the data that give the highest entropy. The experiment has shown to support the assumption. To improve the network performance, we try to reduce the overlapped area between the genuine and forgery signature scores.

***Abstract*-We describe an automated method detection and extraction of blood vessels in retinal images. The proposed algorithm is composed of three steps: gaussian filtering, entropy thresholding and label filtering. First, the gaussian filter technique is to enhance visualization of the blood vessels in retinal image. Secondly, the entropy thresholding is to keep the spatial structure of vascular tree segments and remove a kind of lesion (i.e., hard exudates). Finally, label filter technique is used to remove misclassified pixels. The algorithm has been tested on ten hard exudates in ocular fundus images, and experimental results are compared with clinically generated vessel segmentation and are evaluated in terms of sensitivity and specificity. This method performs well in analyzing anatomical structures in retinal image.**

I. INTRODUCTION

The automatic detection of blood vessels in the retinal images can help physicians for the purposes of diagnosing ocular diseases, patient screening, clinical study, and etc. Information about blood vessels in retinal images can be used to detect the severe retinal diseases such as diabetic retinopathy from an abnormal retinal image. A typical fundus image of patient along with normal components such as arteries, veins, fovea and the optic disc is shown in Fig. 1. The example of lesion (i.e., hard exudates) can be observed on the retinal image.

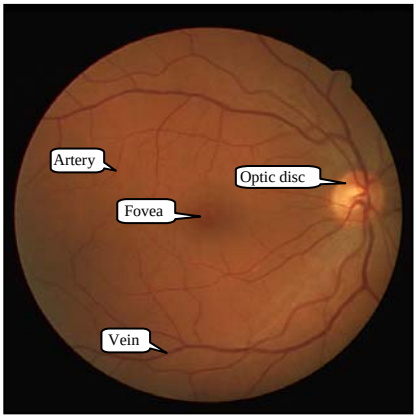

Figure 1. Magnetization as a function of applied field.
Note how the caption is centered in the column.

There are many previous works on extracting blood vessels in retinal images. In edge detection-based method [1], An efficient piecewise threshold probing technique was proposed in [3] where the matched-filter-response (MFR) image is used for mapping the vascular tree. A set of criteria is tested to determine the threshold of the probe region, and ultimately to decide if the area being probed is a blood vessel. Therefore, the different threshold techniques can be applied throughout the image for mapping blood vessels.

In this paper, we propose a new algorithm to remove hard exudates and extract blood vessels in ocular fundus images. The segmentation results are compared with clinically generated vessel segmentations and assessed in terms of their sensitivity and specificity of vessel identification.

II. THE PROPOSED ALGORITHM

The proposed algorithm is composed of three steps. Since blood vessels usually have lower reflectance compared with the background, we separate a green component of retinal image as shown in Fig. 2, we apply green component of retinal image with the gaussian filter to enhance blood vessels with the generation of a GMF image. Secondly, an entropy thresholding scheme can be used to distinguish between vessel segments and the background and remove hard exudates in the GMF image. A label filtering technique is used to remove misclassified pixels.

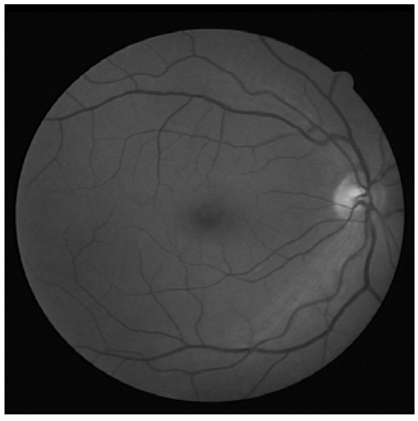

Figure 2. Green component of retinal image

A. Gaussian Filter

The section of a blood vessel is intensity profile which can be approximated by the Gaussian curve [6]. A single intensity

profile of the vessel is cross section, a significant improvement can be achieved by matching a number of cross sections of identical profile simultaneously. Thus, a kernel can be used which mathematical expression is as follows

$$f(x,y) = \frac{1}{\sqrt{2\pi}\sigma}\exp\left(-x^2/\sigma^2\right) \quad \text{for } |y| \le L/2, \qquad (1)$$

where L is the length of the segment for which fixed orientation has been assumed. The direction of the blood vessel here is assumed to be aligned along the y-axis. Because a vessel may be oriented at any angle, the kernel needs to be rotated for all possible angles. A set of twelve 15x16 pixel kernels is applied to convolve with the retinal image, and at each pixel only the maximum of their responses is retained, its GMF image is shown in Fig. 3, where we can see blood vessels are significantly enhanced.

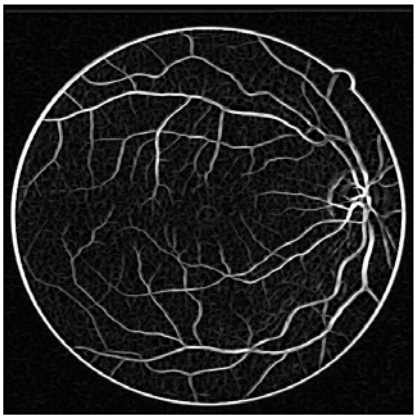

Figure 3. Gaussian filtering result with $\sigma = 1$

B. Entropy Thresholding

Secondly, the GMF image is processed by a proper thresholding scheme in order to extract the vessel segments from the background. An efficient entropy thresholding algorithm. We implement a entropy thresholding technique, described in [2] which can well preserve the spatial structures in the binarized/thresholded image. The co-occurrence matrix of the image F is an P x Q dimensional matrix $T = [t_{ij}]_{PxQ}$ that gives an idea about the transition of intensities between adjacent pixels, indicating spatial structural information of an image. Depending upon the ways in which the gray level i follows gray level j, different definitions of co-occurrence matrix are possible. Here, we made the co-occurrence matrix asymmetric by considering the horizontally right and vertically lower transitions. Thus, t_{ij} is defined as follows:

$$t_{ij} = \sum_{l=1}^{P}\sum_{k=1}^{Q}\delta \qquad (2)$$

where

$$\delta = 1 \quad if \begin{cases} f(l,k) = i & and \quad f(l,k+1) = j \\ f(l,k) = i & or \\ & and \quad f(l+1,k) = j \end{cases}$$

$$\delta = 0 \quad otherwise$$

The probability of co-occurrence p_{ij} of gray levels i and j can therefore be written as

$$p_{ij} = \frac{t_{ij}}{\sum_i \sum_j t_{ij}} \qquad (3)$$

If s, $0 \le s \ge L-1$, is a threshold. Then a can patition the co-occurrence matrix into 4 quadrants, namely A, B, C and D show in Fig. 4.

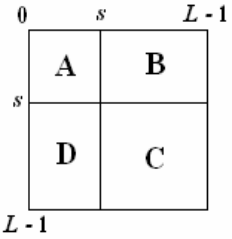

Figure 4. Partition of co-occurrence matrix

Let us define the following quantities:

$$P_A = \sum_{i=0}^{s}\sum_{j=0}^{s} p_{ij}$$
$$P_C = \sum_{i=s+1}^{L-1}\sum_{j=s+1}^{L-1} p_{ij} \qquad (4)$$

Normalizing the probabilities within each individual quadrant, we get the following cell probabilities for different quadrants:

$$P_{ij}^C = \frac{p_{ij}}{P_C} = \frac{t_{ij}}{\sum_{i=s+1}^{L-1}\sum_{j=s+1}^{L-1}} \qquad (5)$$
$$\text{for } s+1 \le i \le L-1, s+1 \le j \le L-1$$

Similarly,

$$P_{ij}^A = \frac{p_{ij}}{P_A} = \frac{t_{ij}}{\sum_{i=0}^{s}\sum_{j=0}^{s} t_{ij}} \qquad (6)$$
$$\text{for } 0 \le i \le s, 0 \le j \le s$$

The second-order entropy of the background can be defined as follows:

$$H_C^{(2)}(s) = -0.5 \sum_{i=s+1}^{L-1} \sum_{j=s+1}^{L-1} P_{ij}^C \log 2\, P_{ij}^C \quad (7)$$

Similarly, the second-order entropy of the object can be written as

$$H_A^{(2)}(s) = -0.5 \sum_{i=0}^{s} \sum_{j=0}^{s} P_{ij}^A \log 2\, P_{ij}^A \quad (8)$$

Hence, the total second-order can be written as

$$H_T^{(2)}(s) = H_A^{(2)}(s) + H_C^{(2)}(s) \quad (9)$$

The gray level corresponding to the maximum of $H_T^{(2)}(s)$ gives the optimal threshold for object and background classification. For the entropy thresholding result is shown in Fig. 5 where we can see blood vessels are clearly segmented from the background.

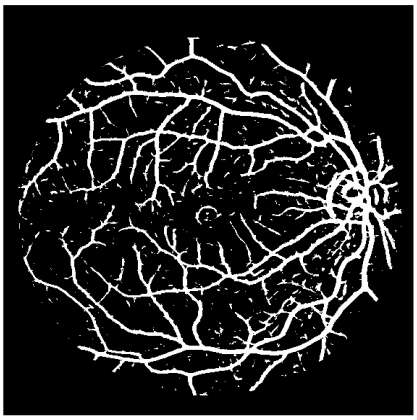

Figure 5. Entropy thresholding result

C. *Label filtering*

Label filtering is used to remove some misclassified pixels in image as shown in Fig. 5, we want to clean image and complete vascular tree structure. Label filtering is used to remove isolated pixels by using the concept of connected pixels labeling. The Label filtering tries to isolate the individual objects by using the eight-connected neighborhood and label propagation [5].The result after label filtering shows in Fig. 6.

III. Experiment and Results

On Pentium 4, CPU 2.6 GHz, using Matlab version 7.3, the computational time of the whole algorithm takes approximately a few minutes for each retinal image. We use the twenty sets are images of normalities. The retinal images and blood vessel ground truth data are obtained from the Image Sciences Institute [10]. In order to compare our of algorithm results with the state-of-the-art results obtained from [10] and hand-labeled groundtruth segmentations as shown in Fig. 7.

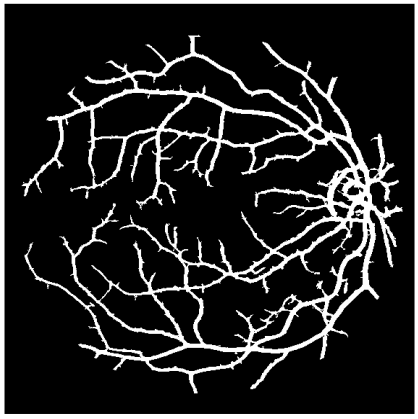

Figure 6. Label filtering result

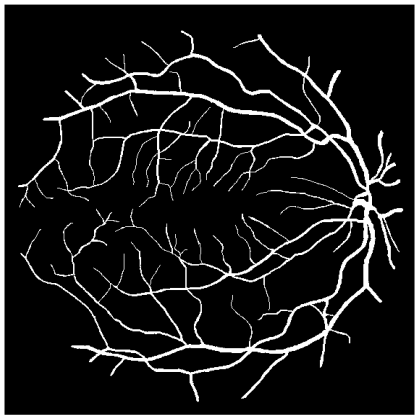

Figure 7. Hand-labeled ground truth segmentations of [10]

The performance of the blood vessel segmentation algorithm is conventionally measured using sensitivity and specificity. The definitions of the two indices are follows:

$$Sensitivity = \frac{Total\ number\ of\ \ positive\ correctly\ identified}{Total\ number\ of\ \ positives} x100 \quad (10)$$

$$Specificity = \frac{Total\ number\ of\ \ negatives\ correctly\ identified}{Total\ number\ of\ \ negatives} x100 \quad (11)$$

The resulting extracted blood vessel in terms of sensitivity and specificity using a stand set of hand-labeled segmentation data. The performance achieved is very promising, showing sensitivity and specificity of 78.16% and 95.75% respectively, and show the average sensitivity and specificity of the twenty test images obtained using other algorithms, the some result from other is shown in Fig. 8.

IV. CONCLUSIONS

In this paper, we have introduced an efficient algorithm for fully automated blood vessel detection in retinal image using the entropy thresholding scheme. It can be helpful in monitoring of the angiogenesis process stimulated more than otsu thresholding scheme [9]. The result of algorithm is compare otsu thresholding is shown in Fig. 9, and in this Fig. 9(e) can see thick blood vessel and thin blood vessel better than Fig. 9(d). In the future we can use algorithm help the doctor to analyse diabetic retinopathy.

***Abstract* — This paper presents an identification approach for an early-state cervical cancer called carcinoma *in situ* (CIS). Size of nucleus and cytoplasm of a squamous cell in the Pap (Papanicolaou's) smear image is related to the cancer in CIS state. Segmentation techniques for the single squamous cell and the combined squamous cells are proposed. A proportion of the segmented nucleus area and the segmented cytoplasm area is computed and used as an indicator of the normal cells and the abnormal cells. To evaluate a performance of the proposed approach, 20 Pap smear images with 30 cells, 10 abnormal cells and 20 normal cells, have been tested. Experimental study with real ground-truth-known images demonstrated the feasibility and promising of the proposed techniques in discriminating between normal cell and abnormal CIS cell. The results reveal 80% accuracy approximately.**

I. INTRODUCTION

Cervical cancer is the second most common cancer in women worldwide, exceeded only by breast cancer [1]. The mortality related to cervical cancer can be reduced if this disease is detected at its carcinoma *in situ* (CIS) state, known as squamous intraepithelial lesion (SIL) [2].

Currently, the primary screening tool for detection of cervical cancer and its precursor is the Pap (Papanicolaou's) smear test [3]. In the Pap test, a large number of cervical cells obtained by scraping the cervical epithelium are smeared onto a slide which is then fixed and stained for cytologic examination. Each smear is then examined under a microscope for the presence of neoplastic cells [4]. Figure 1 shows an example of the Pap smear test [5]. The Pap smear is unable to achieve a concurrently high sensitivity and high specificity [6]. The accuracy of the Pap smear is limited by both sampling and reading errors [7]. Approximately 60% of false-negative smears are attributed to insufficient sampling, while the remaining 40% are due to reading errors. Because of the monotony and fatigue associated with reading Pap smears (50,000–300,000 cells per slide), the American Society of Cytology has proposed that a cyto-technologist should be limited to evaluating no more than 12,000 smears annually [8]. As a result, accurate Pap-smear screening is labor intensive and requires highly trained professionals.

However, Pap smear test is popular at this time even though the accuracy is limited. Because, it can be a final decision of pre-cancer and carcinoma *in situ*, while another method can not make these decisions.

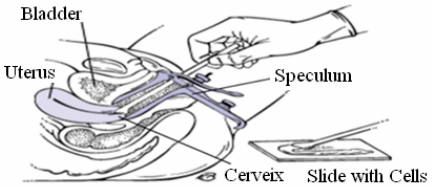

Figure 1. Pap smear test [5].

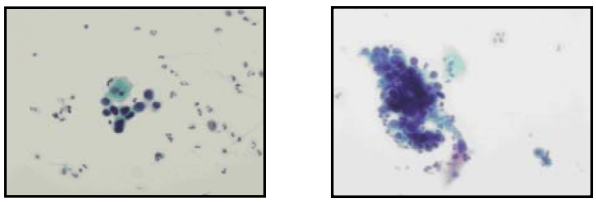

(a) (b)

Figure 2. Examples of Pap smear images: (a) single cells (b) combined cells.

Carcinoma *in situ* is the cervical cancer in the first stage, which is an abnormal deep-basal cell. This cell is a class of squamous cell. Therefore, if a final decision can be made accurately at the moment stage, the physician can be protect patient in due time. The incidence of cervical cancer mortality will be dramatically reduced. Figure 2 shows examples of Pap smear images with squamous cells.

From histological knowledge, the cytologist can make a final decision of carcinoma *in situ* by comparing between nucleus and cytoplasm in the cell.

There were some research works trying to find the comparison. For instance, Bak *et al.* [9] proposed an efficient segmentation method that exploits local information for automated cell segmentation. This method is proved to be resistant to the heavy noise and is not restricted to a particular noise environment represented by specific noise distribution form. Luck *et al.* [10] proposed the model and segmentation algorithm for reflectance confocal images of *in vivo* cervical tissue. Lassouaoui and Hamani [11] proposed genetic algorithms and multifractal segmentation of cervical cell image. Alan *et al.* [12] proposed segmenting cervical epithelial nuclei from confocal images by using Gaussian Markov random

fields. There is trying in several research papers in this field to develop the process. This paper applies shape-based approach by using a region size of cytoplasm campared to nucleus (C/N). Adaptive thresholding and segmentation of squamous cell is proposed. Carcinoma *in situ* cell is then identified.

In rest of this paper is arranged as follows. Section II discusses on the data collection and basis concept. The proposed method is in Section III. The experimental results are presented in Section IV. The paper ends in Section V with a summary.

II. Data Collection and Basic Concept

Class of squamous cell consists of deep basal cell, parabasal cell, intermediate cell and superficial cell, as shown in Figure 3. We have to know the structure of each cell in each class of squamous cell, because carcinoma *in situ* is the cervical cancer that happens in this class of deep basal cell. Table I shows comparison of size, color of cytoplasm, size of nucleus and ratio of cytoplasm and nucleus (C/N) of each normal squamous cell.

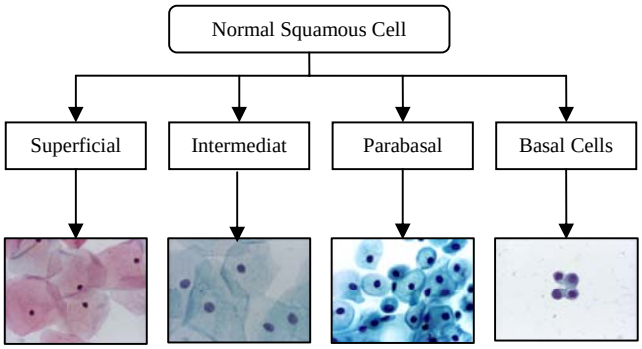

Fig.3. Types and structures of squamous cell.

Table I
Comparison of Size and Color of Normal Squamous Cell

	Deep basal	Parabasal	Intermediate	Superficial
Size of Cell	8-10µm	15-25µm	30-60µm	40-60µm
Color of Cytoplasm	dark blue	blue	pink or blue	orange
Size of Nucleus	7-9µm	8-13µm	10-12µm	5-7µm
Cytoplasm / Nucleus (C/N)	10/8	10/5	10/2	10/1

Table I shows a standard size, color of cytoplasm, size of nucleus and cytoplasm/nucleus (C/N) which is the data pointing to normal squamous cell and abnormal squamous cell. That is to say that if deep basal cell has a size of cytoplasm compared to nucleus less than 10/8 (C/N), it is carcinoma *in situ.*

This paper proposed an approach based on this basic concept. There are two problems of identifying squamous cells to be considered. Case I is for the cells with unclear border. Case II is for the overlapped cells.

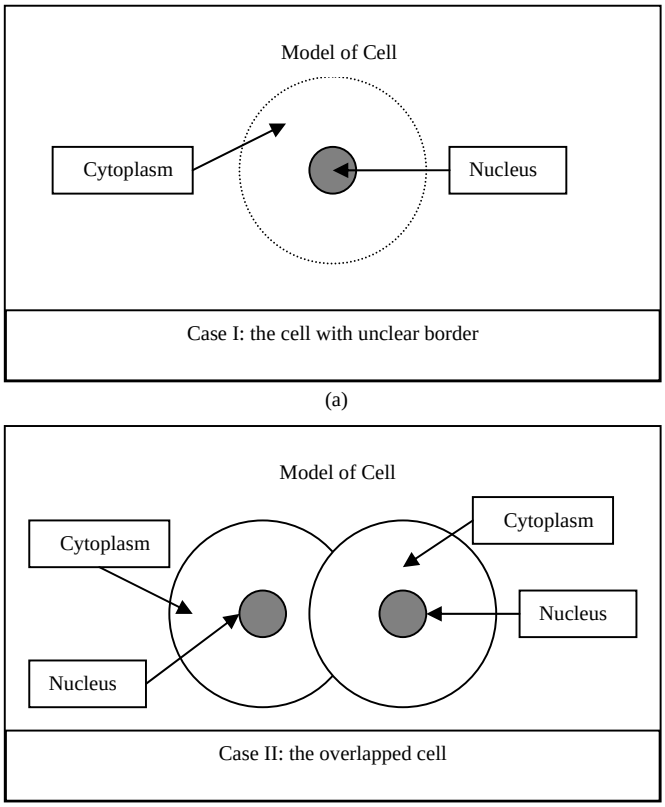

Figure 4. The problem conditions.

In the Figure 4 (a), the problem of this case is that the border of the cell cannot be detected clearly. Therefore the cell's area enclosed by this border is not clear. In Case II, shown in Figure 4 (b), the cells are overlapped.

III. Proposed Method

This paper proposes an identification approach for carcinoma *in situ* cervical cells according to the basic concept. The proposed approach can be described step by step as follows.

Step of software flow diagram in Figure 5 is:

Step 1: Input cell image,
Step 2: Grey level image is adjusted to reduce the background,
Step 3: Adaptive thresholded image for clear border cell,
Step 4: Binary image for cutting the remaining background,
Step 5: Image segmentation for detecting contour and area of the cell, and
Step 6: Classifying cell based on searching area by using basic set operation.

Each set may represent one object, as shown in Figure 6. Each pixel (x,y) has its status: belong to a set or not belong to a set. In the Case II, the logical operation is shown in Figure 7.

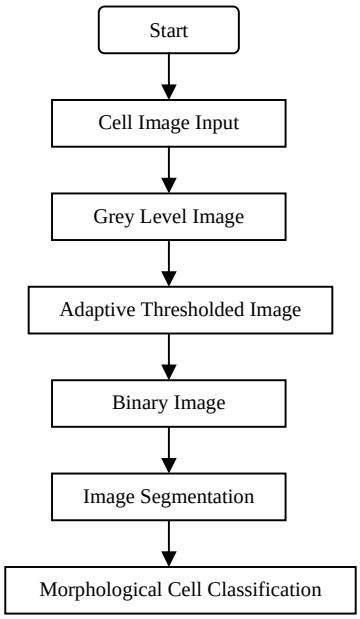

Figure 5. Software flow diagram.

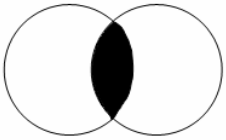

Figure 6. Case II for the intersection of A and B

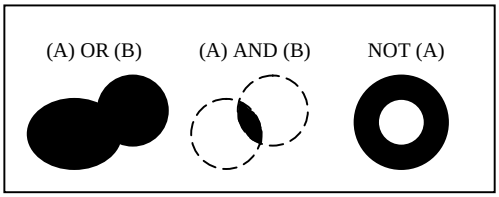

Figure 7. The morphological separation of the intersection of A and B.

IV. Experimental Results

A. Case I Results

In this case, the proposed approach is based on the basic concept that is to resolve the unclear border of the cell. The results are shown in Figure 8.

B. Case II Results

In this case, the results of the proposed approach based on the basis concept to separate the overlapped cells are shown in Figure 9.

The classification results of carcinoma *in situ* cells and normal cells are in the Table III, which C/N Range is a ratio of cytoplasm and nucleus (C/N). In the table, it shows a percentage of tested normal cells and tested abnormal CIS-cells. Fig. 10 shows the classification rate of normal cells and CIS cells from Table III. Twenty real Pap smear image with clinical ground-truth-known is used in the experiments. There are 30 cells: 20 normal cells and 10 carcinoma *in situ* cells. The C/N values are computed and ranged to find the relationship of the carcinoma *in situ* incidence. Figure 10 shows that the CIS cells with smaller C/N can be separated from the normal cells significantly.

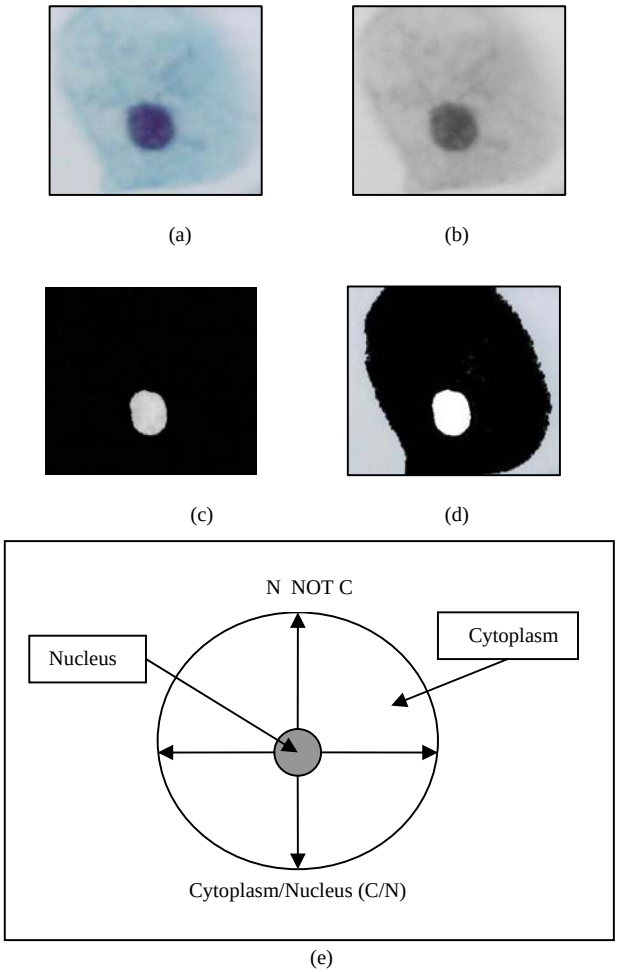

Figure 8. (a) Original image (b) gray level image (c) binary image of nucleus (d) binary image of cytoplasm and (e) nucleus subtracted from cytoplasm for searching nucleus area compared to cytoplasm area.

V. Conclusions

This paper proposes an identification approach for carcinoma *in situ* of Pap smear cervical-cell images. The segmentation of cytoplasm and nucleus of squamous cells is proposed. The results demonstrated that the proposed basis concept and approach reveal promising results from the experiments with the real samples cells.

***Abstract*- This paper shows the fluctuation of some stability parameters. The real data from QST tester shows no significance but the data analysis shows an interested sign. The standard error mean represents the possibility of error at higher applied field. The GMR boundary difference indicates the gap between lower 95% and upper 95% and its fluctuation represents the slider-bar quality. It is found that once the external field is applied, these two analyzed data step up and stay stable. That means some soft ESD may occur and possibly recover after the field is removed.**

I. INTRODUCTION

The recording head with GMR/TMR sensor has been recognized as the most sensitive device for the electrostatic discharge (ESD) effect. In the beginning of magnetoresistive film application for recording heads, the AMR sensor was used and the degree of ESD damage was in orders of 10 V [1-2]. However, the damage of recording head was less important due to its low sensitivity than that in recent years.

It has been currently alert that ESD effect is one of the most crucial effects to recording head when GMR sensor has been firstly manufactured. Many forms of damage such as the breakdown of read element and the bubble of insulator element have been presented [3-4]. They were all called as hard damage which is measurable in terms of resistance and amplitude changes. The visible abnormal increase of resistance and decrease of amplitude can be recognized as a head is totally damaged.

Many experiments have shown that it is due to worker activities and so, the human body model (HBM) has been used to model and simulate this phenomenon [5-6]. Since the dimension of head is scaled down, the ESD damage is becoming more severe.

In manufacturing, many protective possibilities are exercised and hard ESD damage of recording head is currently controllable. Nevertheless, in some process of manufacturing, it is found that some metallic or conductive devices are utilized. This possibly causes an electron move.

Corresponding Author: Apirat Siritaratiwat, Tel/Fax: +66-4334-7442
E-mail: apirat@kku.ac.th

Although an explicit damage cannot be detected by resistive and amplitude measurements, the contour of these two parameter curves are observable or some strange changes are shown. The resistance may be slightly decreased and suddenly increased as the U-shape. Finally it is stable as normal.

When using SEM or TEM to characterize the head, no damage could be observed. However, the soft ESD damage will be exhibited after using for a while. The charged device model (CDM) according to ESDA standard has been simulated to verify this effect.

In our previous demonstrations, a particular process, called "deshunting process", is clearly presented a use of conductive device. It is shown that the direct charge device model (DCDM) can cause a soft ESD effect due to the head conductor contacts [7-8]. This process that was once believed to reduce the ESD effect has been consciously considered in most recording-head production companies.

For more than a decade of ESD studies in recording heads, the Head Gimble Assembly (HGA) has been mainly subjected. This is because that there are many possible processes can be attacked by ESD. A small number of ESD study in Head Stack Assembly (HSA) and Hard-Disk Drive Assembly (HDA) has been published [9-10].

This firstly reports an ESD effect in slider bar level. The aim of this study is to ensure that the ESD effect will not be involved in the slider bar level, prior to transfer to the HGA level. Although standard means and deviations are set for measurements, their standard deviations have never been deeply considered.

II. EXPERIMENTAL SETUP

A couple of parallel charge plates are placed in variable distances and applied by voltage sources. An electric field produced by these two conductive plates is stable and continuous throughout the gap. A sample of slider bar is then inserted into a gap and placed on anti-static sticker as shown in Fig. 1. The voltage sources applied for these plates are DC in order to study the effect of applied field. The Quasi-Static Tester (QST) is used to measure static parameters such as resistance, amplitude, asymmetry and slope of the transfer curve. A number of samples are subjected in order to make sure that it is repeatable.

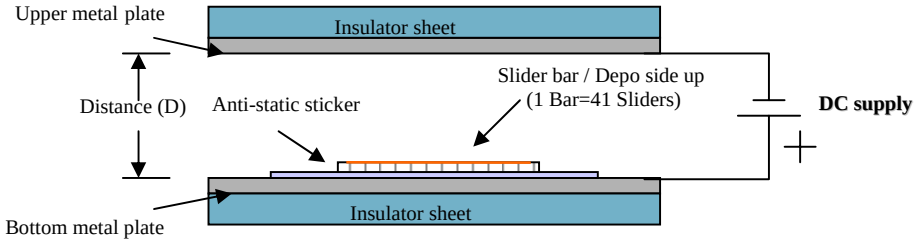

Figure 1 A couple of parallel conductive plates to apply a stable and continuous electric field.

III. RESULTS AND DISCUSSION

A voltage source of 3 steps; 10, 20 and 30 V is applied to fixed 10 cm gap conductive plates within 2 minutes. After applying a voltage of each step, a number of 35 samples are measured for static parameters by using the QST.

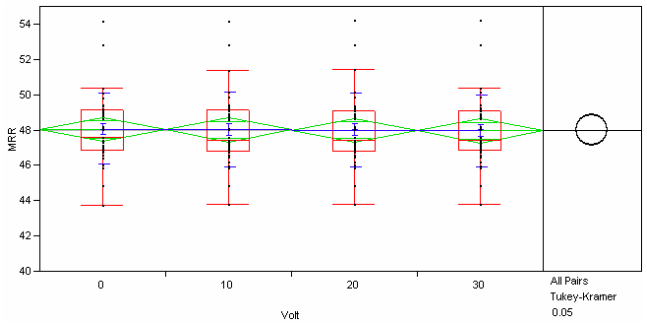

Figure 2 MRR measurements for E = 100-300 V/m.

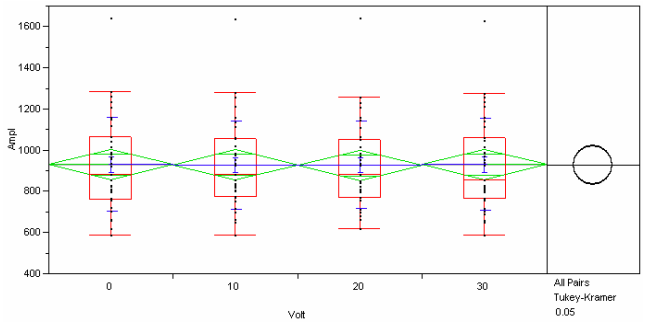

Figure 3 AMP measurements for E = 100-300 V/m.

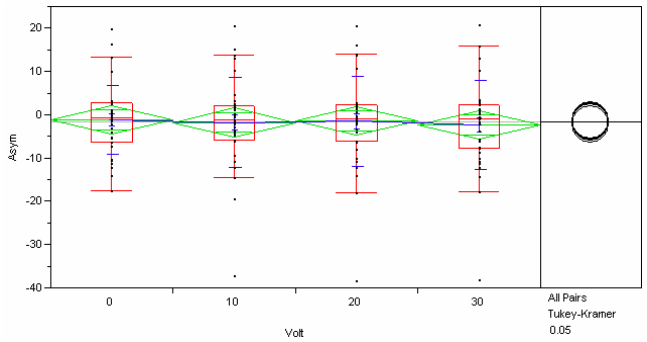

Figure 4 ASYM measurements for E = 100-300 V/m.

The results shown in Fig 2-5 are resistance (MRR), amplitude (AMP), asymmetry (ASYM) and slope (SLOPE). The Tables 1-4 show the means and standard deviations of each experiment.

30	-2.2293	10.2613	1.7345	-5.754	1.2955

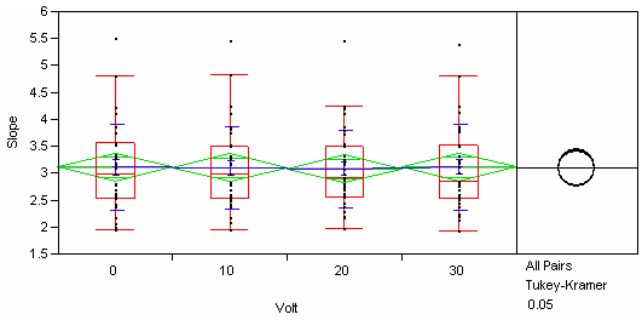

Figure 5 SLOPE measurements for E = 100-300 V/m.

It is expectedly found from Fig 2-5 and Table 1-4 that when an external electric field in an order of 100-300 V/m is applied to a covered slider-bar GMR head these stability parameters are not significantly changed. This is made under the consideration of mean and standard deviation measurements. The standard error mean is statistically calculated where the lower and upper 95% values are correlated with the mean.

The mean of MR is about 48 ohm and a slight fluctuation in a range of 47.9797-48.0600 ohm can be observed. The mean of AMP is about 930 µV with minimum and maximum of 927.941 and 932.656 µV.

The ASYM is varied in a negative range between -1.0765 and -2.293 %. It represents the asymmetry of transfer curve at varied magnetic field and is calculation by [11]

$$\text{ASYM} = \left[\frac{V^+ - V^-}{|V^+| + |V^-|} \right] \text{x}100\% \qquad (1)$$

The SLOPE parameter is calculated in ratio of changes between AMP and applied magnetic field. In this experiment, it changes from 3.09143 to 3.12160 µV /Oe.

It is seen from these results that, in particular, the direct measurement of electrical changes, MR and AMP, shows no obvious evidence because of covered head and very-high electric field protection. An indirect measurement in term of magnetic change is however in possibility and so, the other two parameters are studied.

It is seen in the ASYM measurement as shown in Table 3 that standard-deviations and standard-error means jump immediately after an electric field is applied and the GMR-BD (GMR Boundary Difference), calculated in equation (2), is stepped up as shown in Fig. 6. They seem to be stable under an applied field.

$$\text{GMR-BD} = (\text{Upper } 95\%) - (\text{Lower } 95\%) \quad (2)$$

In addition, the SLOPE measurement fluctuates after 20 V applied field. This is quite explicitly agreed with the ASYM measurement.

TABLE IV
MEAN AND STANDARD DEVIATION OF SLOPE MEASUREMENT

Vap.	Mean	Std. Dev.	Std. Err. Mean	Lower 95%	Upper 95%
0	3.12037	0.809469	0.13683	2.8423	3.3984
10	3.11389	0.764252	0.12918	2.8514	3.3764
20	3.09143	0.725575	0.12264	2.8422	3.3407
30	3.12160	0.792157	0.13390	2.8495	3.3937

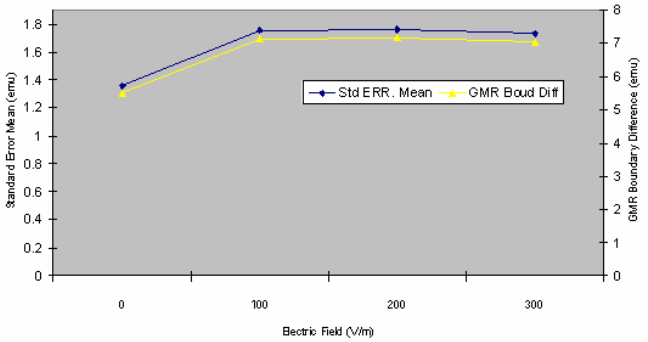

Figure 6 Relationships of applied field, standard-error mean and GMR boundary difference of ASYM measurement.

IV. Conclusion

It is seen from this experiment that 4 testing static parameters can be considered in detail because the raw data give no initiative sign. The measurements of MRR and AMP show no obvious changes but those of ASYM and SLOPE indicate some noticeable data. After evaluation of these last 2 measurements, it is found that the Standard Error Mean and GMR Boundary Difference seem to increase after an external electric field is applied. However, they tend to be stable for higher applied field. It is predictable that this change will be recovered after taking out an electric source. This is possibly due to the soft ESD effect and it will be predictably change again if a field is supplied. However, if the electric field gains higher, some change may be at risk.

***Abstract*- This work is to study the effect of Radio Frequency Identification (RFID) system on MR recording heads, particular in writing process. The variations of current and antenna radius are compared with the angle between a 125 kHz RFID position and HGA. It is found from this result that a current flowing in loop antenna is rather effective than the other. This causes an additional current of 0.4% flowing in HGA compared with an ordinary 50 mA writing current. Although this will not apparently damage a head, it may interfere a writing process especially in a smaller head of the becoming technology.**

I. INTRODUCTION

Radio Frequency Identification (RFID) system is the convenient technology to identify specific data of objects. RFID technology is used in many applications such as livestock, commerce, security and industrial tasks. Generally, RFID system has two important parts which are Reader and Transponder (or Tag). The principle work of RFID is that a reader transmits energy with data in form of an electro magnetic field to a tag for data expression as show in Fig.1. The energy is changed to electric energy and then distributed to the tag circuit. The data with frequency carrier modulation is then reverse to reader for demodulate and reading data.

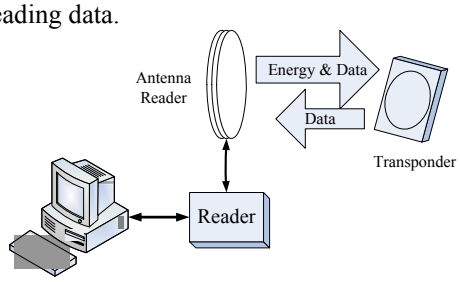

Figure 1. RFID system.

In hard disk drive industry, RFID technology has been applied for accuracy, rapidity and production time saving. However, the production process of hard disk drive components needs to be safely awared a temporary because of its high risks to be damage. Especially magnetoresistive heads (MR Heads) can be destroyed by a very low level of electrostatic discharge, electromagnetic interference etc. Therefore, the utilization of RFID may cause damage in the production components.

This work studies the effect of angle position, distance of RFID installation, current flow in loop antenna and antenna radius of RFID reader that may cause some change in writing process of MR heads. This advantage result show that how to choose an appropriate RFID equipment in the hard disk industry.

II. THEORY

A. Radiated Fields from RFID

To calculate the fields radiated by loop antenna of RFID, the potential function of loop antenna is expressed in (1) and explained in Fig. 2 [1].

$$\vec{A}(x,y,z)=\frac{\mu_o N}{4\pi}\int_c \vec{I}_e(x',y',z')\frac{e^{-jkR}}{R}dl'=\vec{A}_r+\vec{A}_\theta+\vec{A}_\phi \quad (1)$$

where $\vec{A}$ is a potential function of loop antenna,
(x,y,z) is a position of observation point,
μ_o is permeability of free space,
N is a number of turn of loop antenna,
$\vec{I}_e$ is a electric current in loop antenna,
(x',y',z') is an arbitrary position an loop antenna,
R is a distance from (x',y',z') to (x,y,z),
dl' is a tiny arc of loop antenna,
k is wave number,
$\vec{A}_r,\vec{A}_\theta,\vec{A}_\phi$ are potential functions in r-, θ- and ϕ- direction components, respectively.

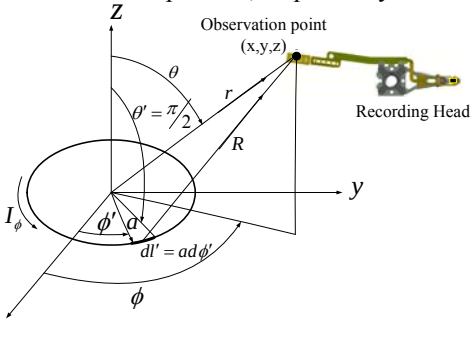

Figure 2. Position of loop antenna reader to observation point.

An electric current, $\vec{I}_e$, is normally composed of 3 component as show in (2)

$$\vec{I}_e=\bar{a}_r I_\phi \sin\theta\sin(\phi-\phi')+\bar{a}_\theta I_\phi\cos\theta\sin(\phi-\phi') \quad (2)$$

where ϕ is an angle between x-axis and observation point on the x-y plane,
ϕ' is an angle between x-axis and arbitrary position on loop antenna.

Since the loop antenna is initially assumed to be on the xy-plan, an electric current, $\vec{I}_e$, is therefore considered in the ϕ - component only as derived in (3).

$$\vec{I}_e = \vec{I}_\phi = I_o \tag{3}$$

where I_o is a current applied into a loop antenna.

The distance, R, can be calculated by (4)

$$R = \sqrt{r^2 + a^2 - 2ar\ \sin\theta\cos\left(\phi - \phi'\right)} \tag{4}$$

where r is a distance between the center of loop antenna and observation point,

a is a loop-antenna radius,

θ is a vertical angle between z-axis and r.

Due to the field is radiated in a free space, a wave number, k , is then computed by (5)

$$k = \omega\sqrt{\frac{\mu_o\varepsilon_o}{2}\left[\sqrt{1+\left[\frac{\sigma}{\omega\varepsilon_o}\right]^2}+1\right]} \approx \omega\sqrt{\mu_o\varepsilon_o} \tag{5}$$

where ω is an angular frequency,

ε_o is a permittivity of free space.

According to the assumption that a loop antenna is placed on the xy-plan the potential function, in (1), is then only composed of ϕ component as show in (6.1) and (6.2)

$$\vec{A}_\theta = \vec{A}_r = 0 \tag{6.1}$$

$$\vec{A}_\phi = \frac{a^2\mu_o NI_o\sin\theta}{4}\left(\frac{jk}{r}+\frac{1}{r^2}\right)e^{-jkr} \tag{6.2}$$

The radiated magnetic field of loop antenna, $\vec{H}$, can be calculated based on Maxwell's equation, in (7),

$$\vec{H} = \frac{1}{\mu}\nabla\times\vec{A} = \vec{H}_r + \vec{H}_\theta + \vec{H}_\phi \tag{7}$$

Since the potential function, $\vec{A}$,has only the ϕ-component, magnetic field in (7) is therefore composed of ϕ - components only as derived in (8.1), (8.2) and (8.3)

$$\vec{H}_r = j\frac{ka^2NI_0\cos\theta}{2r^2}\vec{a}_r\left[1+\frac{1}{jkr}\right]e^{-jkr} \tag{8.1}$$

$$\vec{H}_\theta = -\frac{(ka)^2\ NI_0\sin\theta}{4r}\vec{a}_\theta\left[1+\frac{1}{jkr}-\frac{1}{(kr)^2}\right]e^{-jkr} \tag{8.2}$$

$$\vec{H}_\phi = 0 \tag{8.3}$$

The radiated electric field, $\vec{E}$, can be calculated based on a Maxwell's equation as defined in (9)

$$\nabla\times\vec{H} = \vec{J} + j\omega\varepsilon\vec{E} \tag{9}$$

This electric field is radiated in free space and so, the term of $\vec{J}$ can be neglected due to the conductively of free space, σ , is approximately zero.

It is previously assumed that $\vec{H}$ components are only in r- and θ- directions. Thus, from (9), an electric field, $\vec{E}$, is that only in ϕ - direction as derived in (10.1) and (10.2)

$$\vec{E}_r = \vec{E}_\theta = 0 \tag{10.1}$$

$$\vec{E}_\phi = \eta\frac{(ka)^2\ NI_0\sin\theta}{4r}\vec{a}_\phi\left[1+\frac{1}{jkr}\right]e^{-jkr} \tag{10.2}$$

where η is an intrinsic impedance of free space or about $\approx 120\pi$.

The voltage drop, V_w, across a pair of HGA writing traces, as shown in Fig. 3, can be calculated by (11)

$$V_w = -\int_{r_1}^{r_2}\vec{E}\cdot d\vec{l} \tag{11}$$

From (11) can be easily written in (12)

$$V_w = -\left|\vec{E}\right|\cdot s \tag{12}$$

where s is a gap of HGA writing traces.

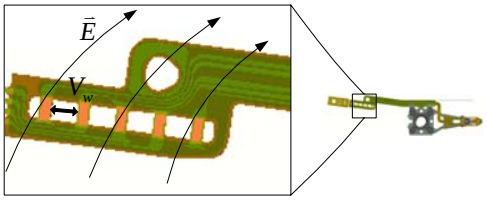

Figure 3. HGA traces.

B. Equivalent circuit of recording head in writing process.

An image of HGA is shown in Fig. 4 and its equivalent circuit of writing component is expressed in Fig. 5.

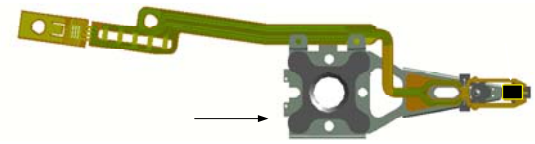

Figure 4. HGA sample.

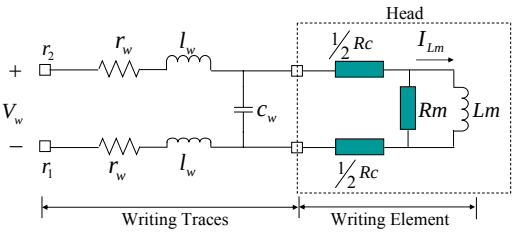

Figure 5. Equivalent circuit of HGA writing component.

In Fig. 5, the required parameters of 2 parts; writing traces and writing element, are that

r_w is resistance of writing trace,

l_w is an inductance of writing trace,

c_w is a capacitance of writing trace space,

R_c is the DC resistance of the coil,

R_m is resistance magnetic losses on the yoke,

L_m is impedance of the head inductance.

The formulas of r_w, l_w and c_w can be found from [2] and expressed in (13) - (15) where the values of R_c, R_m and L_m are defined by their specifications,

$$r_w = \frac{l}{\sigma_w . A_w} \tag{13}$$

$$l_w = \frac{Z_c}{v} \tag{14}$$

$$c_w = \frac{1}{v . Z_c} \tag{15}$$

where l is the length of writing traces,

σ_w is the conductivity of writing traces,

A_w is the cross-section area of writing traces,

Z_c is characteristic impedance of writing traces,

v is velocity of propagation in writing traces.

The characteristic impedance of writing traces, Z_c, can be defined in (16).

$$Z_c = \frac{30\pi}{\sqrt{\varepsilon_r'}} \frac{1}{\left[\frac{W_e}{s} + 0.441\right]} \tag{16}$$

where ε_r' is an effective relative permittivity of polyimide, expressed in Fig. 6,

$\frac{W_e}{s}$ is an effective width of the center conductor.

An effective width of the center conductor, $\frac{W_e}{s}$, can be defined in (17).

$$\frac{W_e}{s} = \begin{cases} \frac{w}{s} & ; \ \frac{w}{s} \geq 0.35 \\ \frac{w}{s} - \left(0.35 - \frac{w}{s}\right)^2 & ; \ \frac{w}{s} \leq 0.35 \end{cases} \tag{17}$$

where w is a wide writing traces,

s is a writing traces space.

The velocity of propagation in writing traces, v, can be defined in (18).

$$v = \frac{1}{\sqrt{\mu_0 \varepsilon_0 \varepsilon_r'}} \tag{18}$$

Therefore, a current, I_{Lm}, flowing in a pair of writing element calculated as a voltage, V_w, divided by a total impedance, as derived in (19)

$$I_{Lm} = \frac{R_m X_{cw} V_w}{(R_m + X_{Lm})\left(R_c + \frac{R_m X_{Lm}}{R_m + X_{Lm}} + X_{cw}\right)\left(\frac{\left(R_c + \frac{R_m X_{Lm}}{R_m + X_{Lm}}\right) X_{cw}}{R_c + \frac{R_m X_{Lm}}{R_m + X_{Lm}} + X_{cw}} + 2r_w + 2X_{lw}\right)} \tag{19}$$

where X_{cw} is capacitive reactance of c_w,

X_{lw} is inductive reactance of l_w,

X_{Lm} is inductive reactance of L_m.

C. *Writing traces information.*

A sample of structure of HGA writing traces and its dimension are shown in Fig. 6 and Table I, respectively [3].

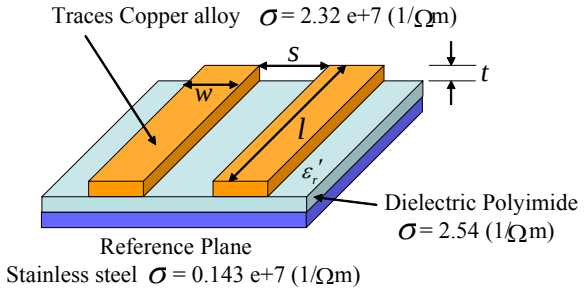

Figure 6. Structure of HGA writing traces.

Table I.
Dimension of HGA writing traces [4]

Dimension	Size
writing traces wide : w	35 µm.
writing traces space : s	50 µm.
writing traces thickness : t	18 µm.
writing traces length : l	50 mm.

III. RESULT ANALYSIS.

A. *Dependent of V_w - I_{Lm} on r and θ.*

The voltage drop, V_w, across a pair of HGA writing traces in (12), calculated as radiated electric field in (10.2), $\vec{E}$, dependent of r and θ. Such, V_w can find in (20) and shown in Fig. 7. The current, I_{Lm}, flowing in a pair of writing element calculated as a voltage, V_w. Such can find I_{Lm} in (21) and shown in Fig. 8. By parameter constant are N = 40 turns and I_o = 100 mA and s = 50 µm

$$V_w = -\left|\eta \frac{(ka)^2 NI_0 \sin\theta}{4r} \bar{a}_\phi \left[1 + \frac{1}{jkr}\right] e^{-jkr}\right| \cdot d \tag{20}$$

$$I_{Lm} = \frac{R_m X_{cw}\left(-\left|\eta \frac{(ka)^2 NI_0 \sin\theta}{4r} \bar{a}_\phi \left[1 + \frac{1}{jkr}\right] e^{-jkr}\right| \cdot d\right)}{(R_m + X_{Lm})\left(R_c + \frac{R_m X_{Lm}}{R_m + X_{Lm}} + X_{cw}\right)\left(\frac{\left(R_c + \frac{R_m X_{Lm}}{R_m + X_{Lm}}\right) X_{cw}}{R_c + \frac{R_m X_{Lm}}{R_m + X_{Lm}} + X_{cw}} + 2r_w + 2X_{lw}\right)} \tag{21}$$

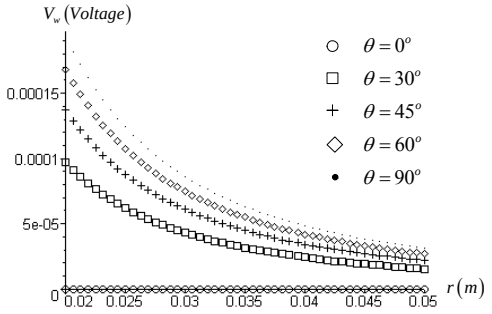

Figure 7. Voltage drop across a pair of HGA writing traces dependent of

r and θ.

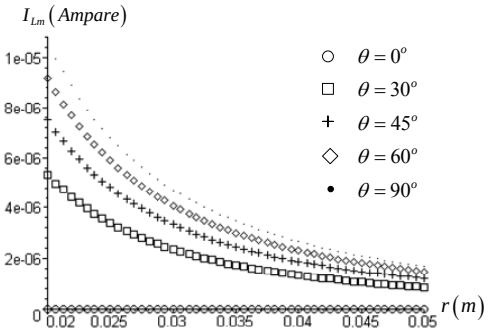

Figure 8. current flowing in a pair of writing element dependent of r and θ.

Therefore, from Fig. 7 and Fig. 8, its mean that the voltage, V_w, and the current, I_{Lm}, non linearly decrease when the distance, r, it long. A maximum voltage, V_w, and the current, I_{Lm}, are capture when the HGA is in the same xy-plane as an antenna loop. However a minimum voltage, V_w, and the current, I_{Lm}, are capture when the HGA perpendicular to an antenna loop.

B. Comparision of I_o - a affect on V_w and I_{Lm}.

The voltage drop, V_w, and the current, I_{Lm}, dependent of I_o and a. Such, can find in (20), (21) and shown in Fig. 9. and Fig. 10. By choose parameters r = 0.02 m. and θ=90° from Fig.7 are affects maximum V_w.

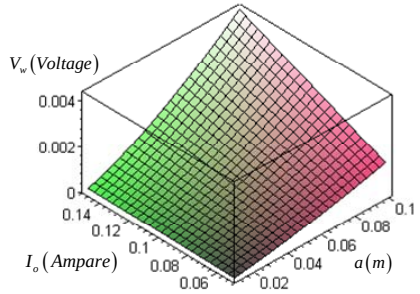

Figure 9. Voltage drop across a pair of HGA writing traces dependent of I_o and a.

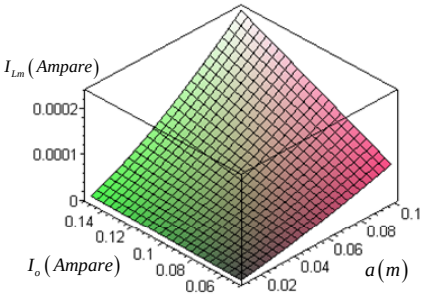

Figure 10. current flowing in a pair of writing element dependent of I_o and a.

Therefore, from Fig. 9 and Fig. 10, its mean that V_w and I_{Lm} increase when the radius of loop antenna, a, and current applied into a loop antenna, I_o, are increase. However V_w and I_{Lm} sensitive increasing dependent of a more than I_o. A maximum V_w and I_{Lm} when $I_o \approx$ 0.15 mA and $a \approx$ 0.1 m.

C. Percentage ratio of I_{Lm} and I_w.

Percentage ratio of I_{Lm} and I_w can find in (22) and shown in Fig. 11.

$$\frac{I_w}{I_{Lm}} \times 100\% \qquad (22)$$

where I_w is standard writing current flow in writing traces $\approx$ 50 mA.

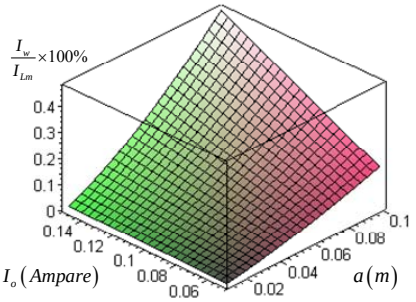

Figure 11. Percentage ratio of I_{Lm} and I_w dependent of I_o and a.

Therefore, from Fig. 11 it mean that I_{Lm} increase when the radius of loop antenna, a, and current applied into a loop antenna, I_o. However I_{Lm} sensitive increasing dependent of a more than I_o. A maximum V_w when $I_o \approx$ 0.15 mA and $a \approx$ 0.1 m.

IV. CONCLUSION.

The effect of electric field which derives from the RFID equipment in the recording head writing process was analyzed, it can identify the parameter which effects to the current flowing through the recording head are the angle θ, distance r, radius a and current flow in loop antenna I_o.

The radius a is the most effect parameter. A maximum ratio of I_{Lm} and I_w about 0.4% ,when a decrease approach zero and current flow in loop antenna I_o increase approach 150 mA.

RFID was designed to be used in the longer distance as in [5]. It indicated that the parameter of the RFID equipment should extend the size. Consequently, the electric field will be stronger which is the topic that will cause the error of the recording head test.

***Abstract*-We developed a three-dimensional finite element model to analyze the effect of the heating from the integrated heater on the effective write field. We consider the effect of the heating into two phenomena; the protrusion of the main pole, and the shrinking of B-H curve of the pole material due to the rising temperature. The combination of these phenomena gives a stronger effective field of 8.3%. We also examine the effect using spin stand tester by measuring the magnetic write width. The experiment results show that the head protrusion also widens the written track. This may present adjacent track interference in the perpendicular recording system.**

I. INTRODUCTION

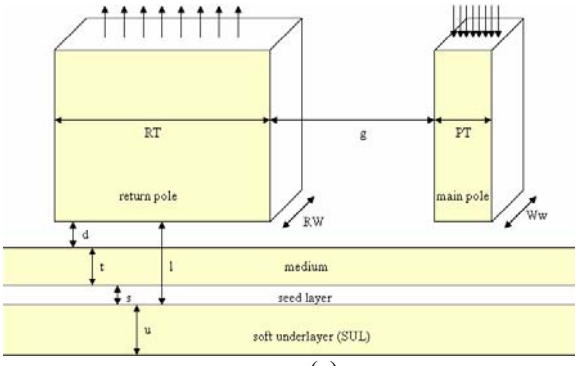
The increase in the areal density of hard disk drives requires the head to fly closer the medium into the order of 10 nanometers [1]. Thus, the variation of flying height for a few nanometers has an influential effect to the recording performance. The flying height variation may depend on many parameters, for example, the air-bearing surface (ABS) and the physical dimensions of slider head. Another cause to reduce the flying height is the head protrusion induced by ambient temperature and write current. Write-induced head protrusion (W-IHP) is caused by power dissipation generated in the head during writing that comprises Joule heating at the coil as well as eddy currents and hysteresis losses in the yoke [2]. However, in high density recording the integrated heater is introduced for the purpose to optimize the flying height of each individual head, so called an adaptive fly height. This heater introduces another protrusion term "heater-induced head protrusion (H-IHP)". Normally, H-IHP can produce a larger stroke than W-IHP. Therefore, the impact of H-IHP to the recording performance should be studied.

This paper investigates the dependence of the effective write field on the head protrusion and the rising temperature at the main pole using a simulation model. Then, we interpret the change of effective field properties into the variation of recording performance. Finally, we also experimentally study on the impact of head protrusion to electrical performance of the recording system using the spin stand tester.

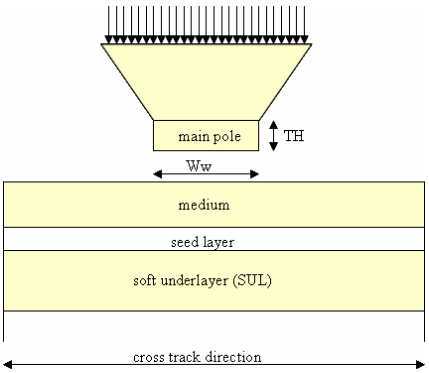
II. MODELS AND SIMULATIONS

A. Simulation Model

We use the commercial ANSYS software to perform three-dimensional (3-D) finite-element modeling. Our model consists of a single main pole, a return pole, and a medium with soft under layer (SUL) as shown in Fig.1 (a). In this model, the main pole with a tapered-neck pole and a very small throat height is proposed as shown in Fig. 1 (b). To reduce the skew-angle sensitivity, the ABS of this main pole is designed to be trapezoidal shape with a wall angle of 15°. The recording system parameters are shown in Tab. I. It is the fact that the magnetic field magnitude depends on the potential difference between the main pole and the SUL. In this model, a positive magnetic scalar potential is applied to the top surface of the main pole and a zero potential is applied to the bottom surface of the SUL. To keep the same amount of magnetic flux flowing out to the return pole, a proportional negative potential is applied at the top surface of the return pole. The perpendicular and longitudinal components of the magnetic field are measured at the center of the recording layer.



(a)



(b)

Figure 1 (a) A simulation model for perpendicular recording system and (b) A tapered-neck main pole with a small throat height.

Head to SUL spacing, HKS	35 nm
Media Thickness	15 nm
μr of Media	2
Interlayer Thickness	5 nm
SUL Thickness	200 nm
Bs of SUL	16 KG
μr of SUL	500

B. Write Field Comparison

It is well known that not only the field magnitude but also the angle between the write field and the easy axis of the medium grain effects to the writability of perpendicular recording heads. This effect can be evaluated using the Stoner-Wohlfarth model. This model gives the following relation [3]:

$$\frac{H_S}{H_K} = (\sin^{2/3}\theta + \cos^{2/3}\theta)^{-3/2} \qquad (1)$$

where H_S is the switching field, H_K is the anisotropy field of the medium, θ is an angle between the write field and the media easy axis.

The switching field H_S may be considered as an effective field H_{EFF} . This field can be obtained from

$$H_{EFF} = \sqrt{H^2_{PERP} + H^2_{LONG}} \times (\sin^{2/3}\theta + \cos^{2/3}\theta)^{3/2} \qquad (2)$$

where H_{PERP} is the field perpendicular to the medium plane, H_{LONG} is the longitudinal field which is the vector combination of the down-track and cross-track fields.

Fig.2 shows the write field components in the case that the magnetic scalar potential of 0.06 A is applied to the top surface of the main pole. The result exhibits the following magnitudes of the write field components and the field angle: $H_{DOWN-TRACK}$ = 1604 Oe, $H_{CROSS-TRACK}$ = 163 Oe, H_{PERP} = 8533 Oe, H_{EFF} = 10793 Oe, field angle = 17.15 degrees. H_{EFF} exhibits a peak value at the region above the trailing edge of the main pole. The maximum of the field angle is shifted from the trailing edge in the down-track direction. In this case the cross-track component is close to zero and it can be negligible. However, the cross-track component becomes significant if we plot the field in cross-track direction.

Fig.3 shows the dependence of the effective write field on the heating from the integrated heater. We may consider the effect of the heating into two phenomena; the protrusion of the main pole perpendicular to the medium plane, and the shrinking of B-H curve of the main-pole material due to the rising temperature [4]. Therefore, there are four difference sets of the input for this calculation as in Tab. II. In Case I, the condition is that the heater power is turned off. H_{EFF} exhibits a magnitude of 10793 Oe, therefore, it is equal to the effective field in Fig. 2. If only the rising temperature is considered (Case II), the magnitude of H_{EFF} is 10318 Oe or it is lower than that of the Case I by 3.92 %. If only the head protrusion is taken into account (Case III), the fly height reduction of 5 nm drives H_{EFF} to shows a magnitude of 12219 Oe or increased by 13.2% comparing to Case I. If both phenomena are combined in the simulation (Case IV), H_{EFF} exhibits a magnitude of 11693 Oe or increased by 8.3%.

Fig.4 shows the effective field measured above the trailing edge in all cases as a function of the cross-track position. It indicates an identical trend comparing to the effective field in the down-track position.

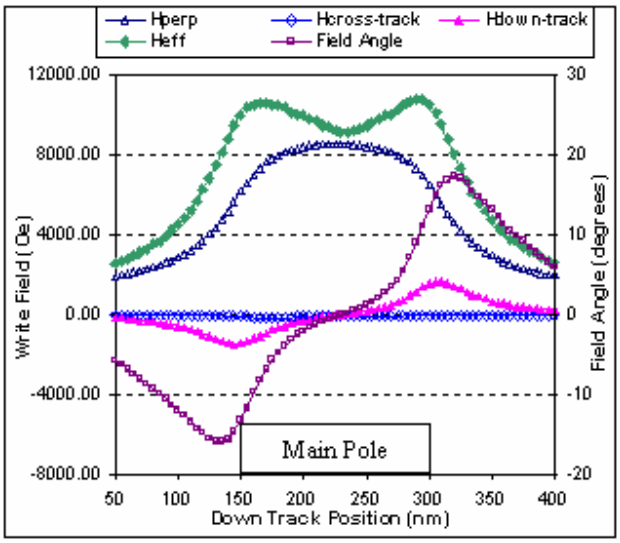

Figure 2. The write field components and the field angle in down-track position.

TABLE II
CALCULATION CONDITIONS

Case	Calculation Condition	HMS	B-H Curve
I	No protrusion and temperature	15 nm	As in Tab. I
II	Only temperature	15 nm	5% decrease of Tab.I
III	Only head protrusion	10 nm	As in Tab. I
IV	Both protrusion and temperature	10 nm	5% decrease of Tab.I

Fig.5 shows the magnitude of the effective field of all four cases above as a function of the applied magnetic scalar potentials. It shows that the difference of the effective field magnitude due to the effect of head protrusion and rising temperature becomes larger at higher magnetic scalar potential.

The rising temperature causes to decrease the effective field while the head protrusion leads to increase the field. However, the effect of the head protrusion is a dominant factor resulting that the effective field is increased by 8.3%. Normally, the stronger effective field gives a better writability. However, the wider pulse of the effective field in cross-track direction may lead to enlarge the written track and it may have a potential to interfere an adjacent track.

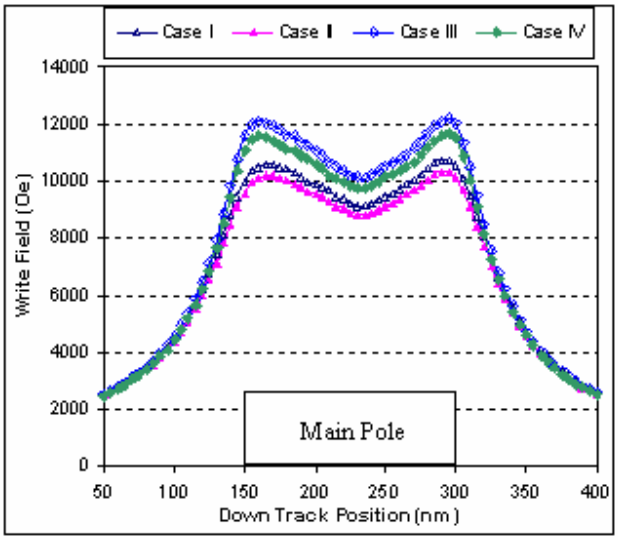

Figure 3. The dependence of the effective write field in down-track position on the heating from the integrated heater.

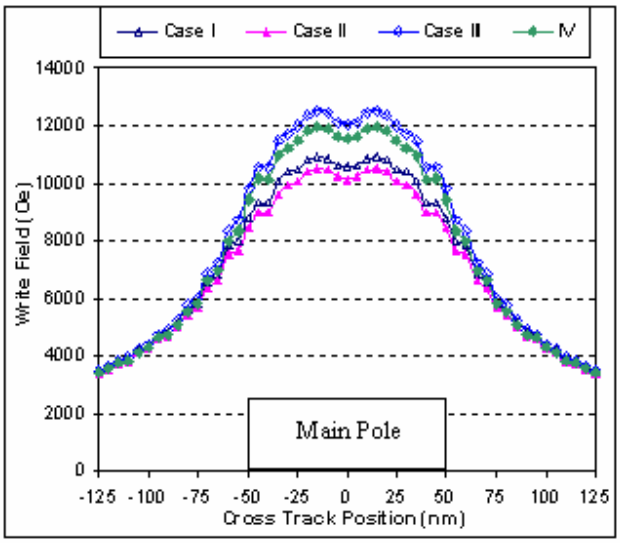

Figure 4. The dependence of the effective write field in cross-track position on the heating from the integrated heater.

Skew Angle (degree)	-11

III. EXPERIMENT

In this experimental setup, a Seagate in-house built spin-stand tester was used. The heads used for this experiment are perpendicular magnetic recording (PMR) heads. The writer head is a trailing shielded single pole head (SSPH) and the reader head is a tunneling magneto-resistive (TMR) head. To investigate the dependence of the recording field on the head protrusion due to the heater power, we measure the dependence of the magnetic write width (MWW) on the flying height by increasing the heater power of 5 mW for each step. The heater power was applied in both write and read cycles. To prevent a head scratch to the media, we firstly measured the clearance between the head and media of all the heads and found out the contact power. It is well known that the head protrusion depends on both the heating from the heater and that from the write current. So, the MWW is measured at three different values of the write current; 50, 60, and 70 mA. The test setup parameters are shown in Tab. III.

The MWW is a very important parameter in characterizing magnetic recording heads. To measure the MWW using spin stand, microtrack profile has been widely used and it is considered to be a standard method. Using the microtrack profile method, the MWW value is defined from the width of a full-track profile at 50% of maximum amplitude [5].

In time-domain, the full-track profile $F(x)$ can be mathematically represented by the convolution between the reader response function and the magnetization of the data track as follows [5]:

$$F(x) = \int R(y)\, M(x - y)\, dy = \int R(y)\, [\theta(x - y) - \theta(x - y - MWW)]\, dy \quad (3)$$

where $R(x)$ is the reader response function, $M(x)$ is the magnetization of the data track in cross-track direction. Generally, $M(x)$ is assumed to have a rectangular shape.

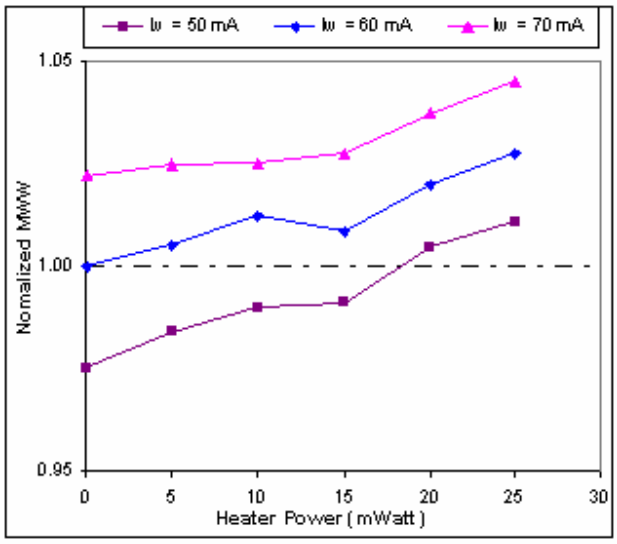

Figure 6. Normalized MWW at different heater powers and write currents.

Fig. 6 shows the plot of normalized MWW as a function of the heater power (normalized to the MWW value at no heater power and write current, I_w, is 60 mA). It exhibits that the higher heater power the larger MWW is. At I_w = 60 mA, the MWW is increased by 2.8% at the heater power of 25 mW. This experimental result agrees with the simulation result that the written track becomes wider due to the head protrusion and it may have a potential to interfere an adjacent track. It also exhibits similar trends when the write current is 50 mA and 70mA. The larger MWW at a higher write current can be classified into two phenomena; the increase of magnetic field due to higher magnetomotive force (mmf) or magnetic scalar potential across the effective gap, and the reduction of flying height due to W-IHP. It is the fact that the higher write current the larger W-IHP is.

IV. CONCLUSION

A 3-D finite element model has been developed to analyze the effective write field which is affected by H-IHP. The results show that the rising temperature which causes to lower *Bs* and μr of the main pole material (5%) decreases the effective field magnitude (3.92% lower than the case of no heating). In contrast, the head protrusion in the direction perpendicular to media plane (5 nm) increases the effective field (13.2% higher than the case of no head protrusion). The combination of these phenomena gives a stronger effective field of 8.3%.

The experiment results show that the head protrusion also widens the written track (through a measure of MWW) for 2.8% at the heater power of 25 mW. This may be explained by the simulation result in which the wider pulse of the effective field in cross-track direction due to head protrusion may lead to enlarge the written track. This larger written track may present adjacent track interference.

ACKNOWLEDGMENT

The authors would like to thank K. Vongsarath at Seagate Thailand for valuable suggestions on the technical issues of perpendicular recording heads and the support on the experiment.

I. INTRODUCTION

Iterative decoding techniques of error correcting codes in magnetic recording system have been of great interest to replace the conventional error correcting codes. Turbo codes and Low Density Parity Check Codes (LDPC) utilize iterative decoding method which shows performance results close to the Shannon limit [1], [2]. However, many researches found that LDPC codes have better outperform Turbo codes for large block size such as [9].

In magnetic recording systems, higher-rate codes must be considered. One reason is that the internal clock rates of read channels inversely scale with code rate. A low code rate, therefore, means a large disadvantage in practice in hardware design. Furthermore, due to thermal instabilities in the media at high area densities, it may not be possible to reliably record at the higher symbol densities required by low code rates [4].

Recently, a type of LDPC codes coined "Modified Array Codes" is proposed [7] for use in communication system for medium code rate. The code is shown to have performance similar to regular/irregular LDPC codes, but possess attractive properties such as simple encoding, low error floor and capability of detecting and correcting burst error.

In this paper, we present a design of Modified Array Codes for high-rate applications such as magnetic recoding system. We show two sets of codes for block sizes common in magnetic recording systems. The effect of permutation matrix size is studied and together with iterative processing, coding gain is achieved.

II. LOW-DENSITY PARITY CHECK (LDPC) CODES

An LDPC code is a binary linear block code defined by a spare parity check matrix. It can be represented by the Bipartite Graph [5]. Suppose that a parity-check matrix $\mathbf{H}$ has n columns and m rows, and the codeword consists of n bits, which satisfy m checks, the number of message bits will be $k = (n-m)$, and the rate of code is $R_c = k/n$. The number 1's in the parity check matrix in rows and columns represents an edge between the $i-th$ bit node c_i and the $j-th$ check node f_j.

An example of the parity check matrix $\mathbf{H}$ of a LDPC code of dimension (m, n) = (3, 7) is shown in Eq. (1).

$$\mathbf{H} = \begin{bmatrix} 1 & 0 & 0 & 0 & 1 & 1 & 1 \\ 0 & 1 & 0 & 1 & 1 & 0 & 1 \\ 0 & 0 & 1 & 1 & 0 & 1 & 1 \end{bmatrix}_{m \times n} \quad (1)$$

The Bipartite or Tanner graph representing the LDPC code can be constructed as shown in Fig. 1.

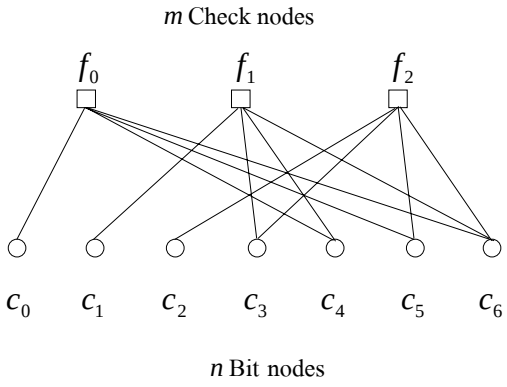

Figure 1. Bipartite or Tanner graph for LDPC code

A disadvantage of general LDPC code is that significant amount of memory is needed to store the parity-check matrix $\mathbf{H}$ due to long input message bits. An Array Code is a structured LDPC code which solves the memory problem since their parity-check matrix consists of the circulant permutation matrices and the identity matrices. In fact, the required memory for storing them can be reduced by a factor $1/p$, when p x p circulant permutation matrices are employed. Moreover, Array codes have capability to detecting and correcting burst error [6].

A. Modified Array Codes

To achieve efficient encoding and minimum distance properties, Eleftheriou [7] proposed a new Array Codes which is known as "Modified Array Codes". A parity-check matrix $\mathbf{H}$ of a modified array codes can be described in terms of the parameter (p, j, k) and has the form

$$\mathbf{H}(p,j,k) \triangleq \begin{bmatrix} \mathbf{I} & \mathbf{I} & \mathbf{I} & \cdots & \mathbf{I} & \cdots & \mathbf{I} \\ \mathbf{0} & \mathbf{I} & \mathbf{P} & \cdots & \mathbf{P}^{(j-2)} & \cdots & \mathbf{P}^{(k-2)} \\ \mathbf{0} & \mathbf{0} & \mathbf{I} & \cdots & \mathbf{P}^{2(j-3)} & \cdots & \mathbf{P}^{2(k-3)} \\ \vdots & \vdots & \vdots & \cdots & \vdots & \cdots & \vdots \\ \mathbf{0} & \mathbf{0} & \cdots & \mathbf{0} & \mathbf{I} & \cdots & \mathbf{P}^{(j-1)(k-j)} \end{bmatrix},$$

where p is prime and $j \le k \le p$, $\mathbf{0}$ is the p x p null matrix and $\mathbf{I}$ is the p x p identity matrix . The matrix $\mathbf{P}$ is a p x p circulant permutation matrix which shifts the identity matrix $\mathbf{I}$ to the right once given in Eq. (2). The permutation matrix can be used to shift the multiplied matrix to the right by i times for any integer i, $0 \le i < p$.

$$\mathbf{P} = \begin{bmatrix} 0 & 1 & 0 & & 0 \\ 0 & 0 & 1 & \cdots & 0 \\ \vdots & \vdots & \vdots & & \vdots \\ 0 & 0 & 0 & \cdots & 1 \\ 1 & 0 & 0 & & 0 \end{bmatrix} \qquad (2)$$

In [7], it is shown that for a modified array code, the minimum distance $d_{\min} = 6$ for $j = 3$ and $d_{\min} \ge 8$ for j = 4. Efficient encoding is achieved from $\mathbf{H}$ without the need to compute the generator matrix of the code. As the upper triangular form of $\mathbf{H}$, there are no cycles of length 4 in the corresponding Tanner graph.

The Modified Array Codes defined by $\mathbf{H}$ has codeword length $N = k \cdot p$, number of parity bit $M = j \cdot p$ and message block length $K = p \cdot (k - j)$ and finally, code rate is $R = 1 - j/k$.

B. Cycles of Modified Array Codes

To understand the cycle properties of Modified Array Codes, we will consider the following a more general from of a parity check matrix $\mathbf{H}$, i.e.,

$$\mathbf{H} = \begin{bmatrix} \mathbf{P}^{a_0 \cdot 0} & \mathbf{P}^{a_0 \cdot 1} & \mathbf{P}^{a_0 \cdot 2} & \cdots & \mathbf{P}^{a_0 \cdot p-1} \\ \mathbf{0} & \mathbf{P}^{a_1 \cdot 1} & \mathbf{P}^{a_1 \cdot 2} & \cdots & \mathbf{P}^{a_1 \cdot p-1} \\ \mathbf{0} & \mathbf{0} & \mathbf{P}^{a_2 \cdot 2} & \cdots & \mathbf{P}^{a_2 \cdot p-1} \\ \vdots & \vdots & \vdots & \cdots & \cdots \\ \mathbf{0} & \mathbf{0} & \cdots & \cdots & \mathbf{P}^{a_{j-1} \cdot p-1} \end{bmatrix} \qquad (3)$$

A cycle of length 2k exits in the Tanner graph of Modified Array Codes with the parity check matrix $\mathbf{H}$ and block row labels $a_0, a_1, \ldots, a_{j-1}$ if and only if there exists a close path $(i_1, j_1), (i_1, j_2), (i_2, j_2), (i_2, j_3), \ldots, (i_k, j_k), (i_k, j_1)$.

The possible cycles in $\mathbf{H}$ is 2k times, and then the length of the cycles in the permutation is described as shown below.

$$\mathbf{P}^{a_{i_1} \cdot j_1} \left(\mathbf{P}^{a_{i_1} \cdot j_2}\right)^{-1} \mathbf{P}^{a_{i_2} \cdot j_2} \left(\mathbf{P}^{a_{i2} \cdot j_3}\right)^{-1} \cdots \mathbf{P}^{a_{ik} \cdot j_k} \left(\mathbf{P}^{a_{ik} \cdot j_1}\right)^{-1}$$

From the result of short cycles properties in [8], the cycles of length 4 depends on the following permutation,

$$\mathbf{P}^{a_{i_1} \cdot j_1} \left(\mathbf{P}^{a_{i_1} \cdot j_2}\right)^{-1} \mathbf{P}^{a_{i_2} \cdot j_2} \left(\mathbf{P}^{a_{i2} \cdot j_1}\right)^{-1} = \mathbf{P}^{(a_{i_1} - a_{i_2})(j_1 - j_2)}$$

which is exact when it is equal to 1. This occurs when $(a_{i_1} - a_{i_2})(j_1 - j_2) \equiv 0$, which is clearly impossible since $i_1 \ne i_2$ and $j_1 \ne j_2$. Hence, there are no cycles of length 4 for Modified Array Codes.

III. THE SUM-PRODUCT ALGORITHM (SPA)

The sum-product algorithm (SPA) is a soft iterative decoding algorithm most commonly used to decode LDPC codes [2-3]. Given that y_i is the i^{th} received channel value corresponding to the i^{th} transmitted codeword c_i . Input of LDPC decoder is in the form of log likelihood ratios (LLRs) $L(c_i) = \log(P(c_i = 0 \mid y_i) / P(c_i = 1 \mid y_i))$.

From Fig 2, the basic operation in the decoding algorithm is shown. In the Tanner graph, the check nodes and bit nodes interchange soft information. Let the variable q_{ij} be the message (information) sent from the i^{th} bit node to j^{th} check node along a connecting edge, and r_{ji} is the message (information) sent from j^{th} check node to the i^{th} bit node along a connection edge. The information q_{ij} is computed based on the values sent from check nodes connecting to the i^{th} bit node excluding the j^{th} bit node.

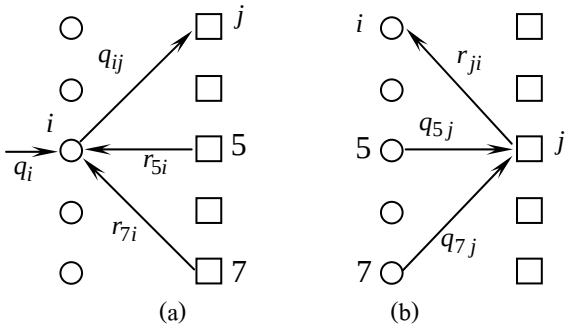

Figure 2. (a) A message is passed from i^{th} bit node to j^{th} check node and (b) A message is passed from the j^{th} check node to the i^{th} bit node.

The Operation of Log-Domain SPA Decoder

The operation of log-domain SPA decoder consists 5 steps, i.e.,

Step 1: Initialization. The LLR value of q_{ij} is set to be equal to the LLR value of the received channel values computed from

$$L(q_{ij}) = L(c_i) = 2y_i / \sigma^2, \qquad (4)$$

where σ^2 is variance of Gaussian noise.

Step 2: Update equation for the message from check nodes to bit nodes given by

$$L(r_{ij}) = \prod_{i' \in V_j \setminus i} \alpha_{i'j} \cdot \phi\left(\sum_{i' \in V_j \setminus i} \phi(\beta_{i'j}) \right), \quad (5)$$

where $\alpha_{ij} = \operatorname{sgn}\{L(q_{ij})\}$, $\beta_{ij} = |L(q_{ij})|$ and define $\phi(x) = \log\{(e^x + 1)/(e^x - 1)\}$ with the base of e. In addition, $V_{j\setminus i}$ represents all the bit nodes except the i^{th} bit node.

Step 3: Update equation for the message from bit node to check node is given by

$$L(q_{ij}) = L(c_i) + \sum_{j' \in C_i \setminus j} L(r_{j'i}) \quad (6)$$

Step 4: For i = 0, 1… n-1, the extrinsic output of decoder is given by

$$L(Q_i) = L(c_i) + \sum_{j \in C_i} L(r_{ji}) \quad (7)$$

Step 5: For i = 0, 1… n-1, the estimated channel input can be computed from

$$\hat{c}_i = \begin{cases} 1, \text{ if } L(Q_i) < 0 \\ 0 \text{ else} \end{cases} \quad (8)$$

If $\hat{\mathbf{c}}\mathbf{H}^t = \mathbf{0}$ or the number of iterations equals the maximum limit, stop, or else, go to Step 2.

IV. Simulation Results and Discussions

The current magnetic recording systems require high code rate such as 8/9 (0.88) and higher and the block size is around 1000 and 4000 bits. In this section, we present the design and performance of modified array codes at high-rate codes with block sizes which are common in magnetic recording systems.

A. Performance results with block size 1100~1300

The Modified Array Codes can be designed by fixing the code rate R and codeword length $N = k \cdot p$ to be around 1,100 – 1,300 bits, and then select p and k respectively. Due to the constraint of high code rates, the parameter j has to be low, given k. The relationship between j and k can be found in Table I. The targeted code rates are in the range of 0.88 – 0.9. Some examples of the designed codes are shown in Table 1.

Table 1: Code parameters with block size 1,100-1,300

j	3	3	3
k	31	29	25
p	37	43	53
$R_c = (1 - j/k)$	0.903	0.897	0.88
Message $p \cdot (k - j)$	1,036	1,118	1,166
Parity bit $j \cdot p$	111	129	159
Block size $k \cdot p$	1,147	1,247	1,325

For high-code rates, it can be observed that the parameter j is small compared with the parameter k. To select the best codes among designed codes, we simulate the performance and compare the results in AWGN channel, but the code rates and code lengths are tailored for magnetic recording systems.. The code performance in terms of the bit error rate (BER) compared with SNR is plotted. In the simulations, we refer to the input signal-to-noise ratio as electronics SNR in AWGN channel and defined it as

$$\left(\frac{E_b}{N_o}\right)_{dB} = \log_{10}\left(\frac{1}{R}\frac{E_c}{N_o}\right),$$

where E_c is the average energy of coded bits, E_b is the average energy of message bits and N_o is noise PSD. Each BER point is computed by using as many data packets as needed to collect at least 1000 error bits. The performance of the targeted block sizes are shown in Fig. 3. Note that the number of iterations in the decoding process is 30. Three modified array codes with code rates of ~0.9 are simulated in this paper. Three different values of p are considered, including 37, 43 and 53. The modified array codes with p = 37 has the worst performance than the other two, in particular, at BER = 10^{-5}, the codes with p = 43 and 53 need the SNR of 4.8 and 4.6 dB, which are less than for the code with p = *37*. The size of permutation matrix **P** evidently affects the code performance. It can be seen that performance is improved when the permutation matrix size increases. As the performance of the decoder is determined by the minimum distance of the code, the codes with larger **P** produces higher minimum distance.

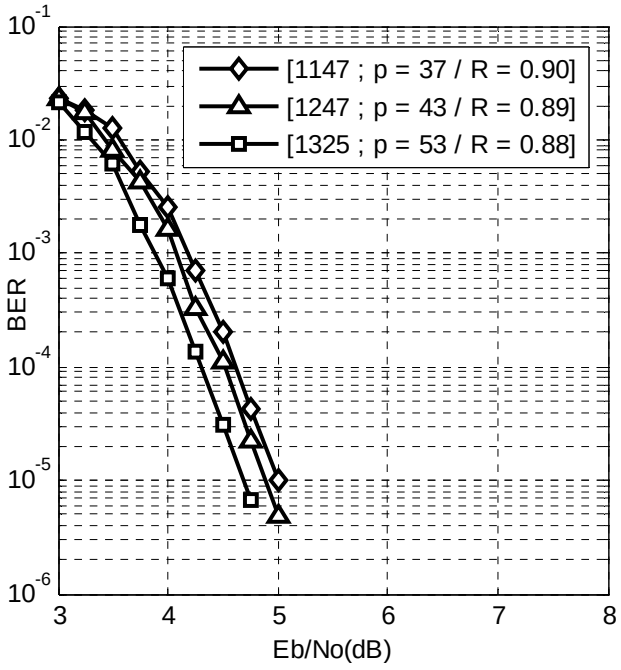

Figure 3. Performance results with block size 1100~1300 with various sizes of permutation matrix (after 30 iterations)

B. Performance results with block size 4000~4100

For this part, we fix the codeword length to be 4,000–4,100 bits, and then adjust the parameter *j*, *k*, and *p*, respectively. The code rate is targeted at 0.89 - 0.92, then the designed codes are shown in Table 2.

Table 2 : Code parameters with block size 4,000-4,100

j	5	5	5
k	61	53	47
p	67	79	89
$R_c = (1 - j/k)$	0.92	0.91	0.89
Message $p \cdot (k - j)$	3,752	3,792	3,738
Parity bit $j \cdot p$	335	395	445
Block size $k \cdot p$	4,087	4,187	4,183

Similar to the result in Fig. 3, the permutation matrix size affects the code performance. Three different values for p are considered, including 67, 79 and 89. The modified array code with p = 67 has the worst performance compared with the other two, in particular, at BER $=10^{-5}$, the code with p = 79 and 89 need 4.5 and 4.25 dB less than that of p = 67 code.

It can be seen that performance is improved when the permutation matrix size increases as well.

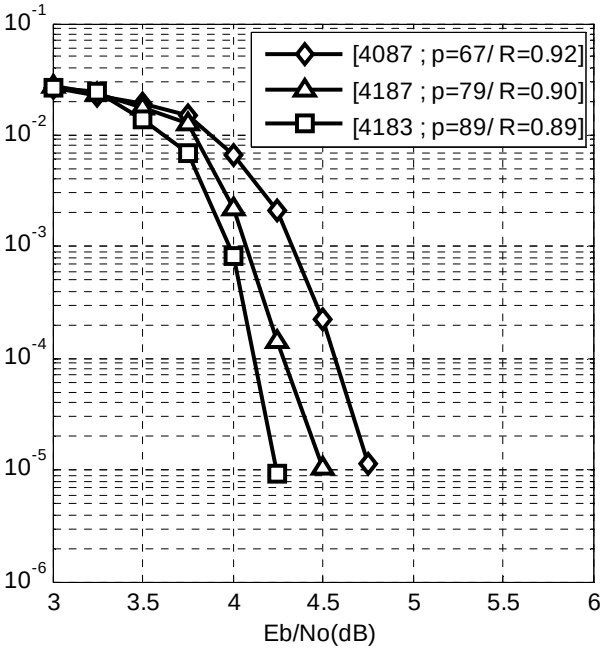

Figure 4. Performance results with block size 4000~4100 with various sizes of permutation matrix (after 30 iterations)

V. CONCLUSIONS

The design of high-rate Modified Array Codes at high code rate with block sizes suitable for magnetic recording system is illustrated. For high-rate codes, the simulation shows that the size of permutation matrix affects the code performance with larger *p* leads to higher minimum distance. This is valid for the both cases of considered block sizes. Modified Array Codes LDPC have been shown to possess suitable properties for magnetic recording system such as low-complexity encoding process, low error floor and capability of detecting and correcting burst. It is, therefore, possible to use the Modified Array Codes together with iterative decoding method, as the error correcting code in the magnetic recording channel. For future works, we plan to evaluate the performance of Modified Array Codes together with turbo equalization in realistic magnetic recording channel model.

***Abstract* - Modified array code is considered a Quasi-cyclic LDPC codes with simple encoding structure. The parity-check matrix is based on identity matrix and permutation matrix. In this paper, we present a new encoding method with encoder circuit designs presented. The encoding is done on one subblock at a time compared to the direct XOR network and does not need matrix inversion. Both Serial and Semi-Parallel circuit structures are constructed for high-rate applications. The circuit complexity in terms of number of logic elements are compared against direct XOR networks for high-rate codes suitable for magnetic recording systems. The direct XOR networks show exponential complexity, while the proposed encoding methods are much simpler and show linear complexity.**

***Keywords*: Quasi-cyclic LDPC codes, FPGA, Modified array codes.**

I. INTRODUCTION

Low-density parity-check or LDPC code is a linear block code defined by a sparse parity-check matrix **H**. The sparseness results in large minimum distance, hence, a large number of correctable errors can be achieved. The codes when combined with iterative processing leads to a performance approaching the Shannon's limit in an additive white Gaussian noise channel. Low Density Parity Check (LDPC) codes was originally discovered in 1960 by Gallager [1] and in 1962, but the high-complexity hindered its usefulness. It was not until in 1996 when in [2], the author rediscovers LDPC and presents the decoding method using Belief Propagation. In [3], S. Y. Chung et. al. showed that LDPC code reaches a Shannon limit within 0.0045 dB. LDPC code comes into two types: regular LDPC code and irregular LDPC code. The encoding problem is typically complex and has been studied by many researchers [4-6]. A type of LDPC codes called quasi-cyclic LPDC (QC-LDPC) code has been studied recently due to the quasi-cyclic structure that allows simpler encoding scheme. In [4], the encoding is based on dividing the parity-check matrix **H** into submatrices to accommodate high-rate application. The encoding is still complex as matrix inversion is required. In [5] specific construction of QC-LDPC codes is based on Permutation matrix **P** to achieve a girth size of 12. The structure allows simpler encoding. In [6], encoding based on generator matrix **G** rather than **H** is presented instead. It is still based on breaking the matrix **H** into submatrices and then translates into the generator matrix **G**. In this paper, we present a block-type encoding of QC-LDPC codes for high-rate application. The simplicity is due to systematic encoding nature and encoding is done on a subblock basis. There is no matrix inversion required and for high-rate application, the numbers of encoding equations are small. In Section II, we review LDPC codes and QC-LDPC codes and some properties. In Section III, encoding equations are derived and encoder circuits are presented. The analysis results and discussions are shown in Section IV and the conclusions are in Section V.

II. LOW-DENSITY PARITY-CHECK (LDPC) CODES

A. *Array-based LDPC code*

An array-based LDPC code or Array code is a type of non-systematic LDPC codes with quasi-cycle property. The parity-check matrix **H** has a structure that allows efficient encoding process. The encoding is done with **H** rather than generator matrix **G** [6]. The quasi-cyclic property dictates that shifted message bits correspond to shifted parity-check bits.

The parity-check matrix **H** has the dimension (n-k) x n, where k is the message length and n is the code length. The matrix **H** can be built from the permutation matrix P with dimension size L x L given by

$$P_{LxL} = \begin{bmatrix} 0 & 1 & 0 & & 0 \\ 0 & 0 & 1 & \dots & 0 \\ : & : & : & & : \\ 0 & 0 & 0 & \dots & 1 \\ 1 & 0 & 0 & & 0 \end{bmatrix} \quad (1)$$

The matrix **P** is a shifted identity matrix **I** one time. The matrix **H** can be built from

$$\mathbf{H} = \begin{bmatrix} I & I & I & \dots & I \\ I & P & P^2 & \dots & P^{k-1} \\ I & P^2 & P^4 & \dots & P^{2(k-1)} \\ : & : & : & : & : \\ I & P^{j-1} & P^{2(j-1)} & \dots & P^{(j-1)(k-1)} \end{bmatrix} \quad (2)$$

Basically, the matrix P expands rowwise by j times and columnwise by k times, respectively.

B. Modified array-based LDPC code

A modified array-based LDPC code or a Modified Array code [7] is an array code with modification so that the codeword is systematic. The parity-check matrix **H** for modified array codes can be described by three parameters (q, j, k), where q is prime and integer number j and k. The matrix **H** has dimension jL x kL, i.e.,

$$\mathbf{H}(q,j,k)=\begin{bmatrix} I & I & I & \cdots & I & \cdots & I \\ 0 & I & P & \cdots & P^{(j-2)} & \cdots & P^{(k-2)} \\ 0 & 0 & I & \cdots & P^{2(j-3)} & \cdots & P^{2(k-3)} \\ & & & & \ddots & & \\ 0 & \cdots & 0 & I & P^{(j-2)} & \cdots & P^{(j-2)(k-j-1)} \\ 0 & 0 & \cdots & 0 & I & \cdots & P^{(j-1)(k-j)} \end{bmatrix} \quad (3)$$

(j | k-j)

The encoding complexity of the modified array code is linear [5]. An expansion of **H** matrix using **P** has a constraint that the rowwise expansion factor must be less than the column wise expansion factor, which is also less than the size of permutation matrix, i.e., $q \geq k \geq j$. The code rate can be computed from

$$R=\frac{k-j}{k}=1-\frac{j}{k} \quad (4)$$

Modified array code possesses a quasi-cyclic property and has a linear encoding complexity.

III. ENCODER CIRCUIT OF LDPC CODES

There are various ways to encode LDPC codes, but in this section, we review direct encoding method of LDPC code. The encoding complexity is linear. Encoding is transforming a message into a codeword. For systematic code, this means adding parity bits. A simple way is to exploit the relationship between coderword and the parity-check matrix **H**. Given a codeword **c** with dimension of 1xn and the corresponding matrix parity check **H** with dimension of (n-k)xn and **0** is a zero matrix with dimension of (n-k)xn. The encoding circuit uses to modulo-2 addition or XOR operation. Consider the relationship

$$\mathbf{cH}^T = \mathbf{0} \quad (5)$$

Transpose both sides of Eq. (5) to obtain

$$\mathbf{Hc}^T = \mathbf{0}^T \quad (6)$$

Let a systematic codeword **c** be in the form of

$$\mathbf{c}=\left[\, p_1\, p_2 \ldots p_{n-k} \;\middle|\; m_1 m_2 \ldots m_k \,\right]=[\mathbf{p}\quad \mathbf{m}] \quad (7)$$

where the parity bits are positioned at the front part and the message bits are at the back part. In this way, the encoding can be done efficiently. The transpose of codeword **c** in Eq. (6) can be written as

$$\mathbf{c}^T=\begin{bmatrix}\mathbf{p}\\ \mathbf{m}\end{bmatrix} \quad (8)$$

Substituting Eq.(8) into Eq.(6), the parity-check equation can be derived. For example, given that a parity-check matrix **H** of a (3, 6) code is

$$\mathbf{H}=\begin{bmatrix}1&0&0&1&0&1\\0&1&0&1&1&0\\0&0&1&0&1&1\end{bmatrix} \quad (9)$$

Rewrite Eq.(8) as

$$\mathbf{Hc}^T=\mathbf{0}^T \quad = \quad \begin{bmatrix}1&0&0&1&0&1\\0&1&0&1&1&0\\0&0&1&0&1&1\end{bmatrix}\begin{bmatrix}p_1\\p_2\\p_3\\m_1\\m_2\\m_3\end{bmatrix}=\begin{bmatrix}0\\0\\0\\0\\0\\0\end{bmatrix} \quad (10)$$

Then the parity-check equation can be listed as

$$\begin{aligned} p_1 + m_1 + m_3 &= 0 \\ p_2 + m_2 + m_1 &= 0 \\ p_3 + m_3 + m_2 &= 0 \end{aligned}, \quad (11)$$

where '+' is a modulo-2 addition or an XOR operation. The parity bits can then be found from

$$\begin{aligned} p_1 &= m_1 + m_3 \\ p_2 &= m_2 + m_1 \\ p_3 &= m_3 + m_2 \end{aligned} \quad (12)$$

A simple circuit diagram can thus be shown in Fig. 1.

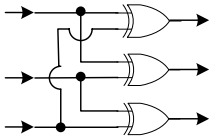

Fig. 1. Direct encoder of a (3, 6) code

Direct method is viable for the code with small k, but in practical applications, the message length can be up to 1024, for example. Given a code rate of ½, the codeword length is n = 2048. The number of parity-check equations is then 1024. The number of XOR operation can be very high and not suitable for encoder circuit design. In the next part, we propose a block-type encoder design.

A. *Subblock-Type Encoder Design of Modified Array Codes*

The encoder complexity can be reduced by encoding each subblock at a time. The matrix H consists of j subblocks rowwise and k subblocks columnwise. Consider a systematic codeword of length $N = kL$ with parity-check part at the front and the message part at the back, i.e.,

$$\mathbf{c} = \begin{bmatrix} \mathbf{p}_1 & \mathbf{p}_2 & \mathbf{p}_3 & \mathbf{p}_4 & \cdots & \mathbf{p}_j & \mathbf{m}_1 & \mathbf{m}_2 & \cdots & \mathbf{m}_{k-j-1} & \mathbf{m}_{k-j} \end{bmatrix} \quad (13)$$

Consider the equation

$$\mathbf{H}\mathbf{c}^T = \begin{bmatrix} I & I & I & \cdots & I & \cdots & I \\ 0 & I & P & \cdots & P^{(j-2)} & \cdots & P^{(k-2)} \\ 0 & 0 & I & \cdots & P^{2(j-3)} & \cdots & P^{2(k-3)} \\ & & & & \ddots & & \\ 0 & \cdots & 0 & I & P^{(j-2)} & \cdots & P^{(j-2)(k-j-1)} \\ 0 & 0 & \cdots & 0 & I & \cdots & P^{(j-1)(k-j)} \end{bmatrix} \begin{bmatrix} \mathbf{p}_1 \\ \mathbf{p}_2 \\ \vdots \\ \mathbf{p}_j \\ \mathbf{m}_1 \\ \mathbf{m}_2 \\ \vdots \\ \mathbf{m}_{k-j} \end{bmatrix} = \mathbf{0}^T, \quad (14)$$

where $\mathbf{p}_i$, $i = 1,2,\ldots, j$ is a subblock of parity bits of size LxL. Thus, each subsection of parity-check bits can be computed from two parts: the higher-indexed parity-check subsection and all the message subsections. The above equations can be written as a set of equations

$$\begin{aligned} \mathbf{p}_j &= \mathbf{m}_1 P^{(j-1)} + \mathbf{m}_2 P^{(j-1)2} + \mathbf{m}_3 P^{(j-1)3} + \cdots + \mathbf{m}_{k-j} P^{(j-1)(k-j)} \\ \mathbf{p}_{j-1} &= \mathbf{p}_j P^{(j-2)} + \mathbf{m}_1 P^{(j-2)2} + \mathbf{m}_2 P^{(j-2)3} + \cdots + \mathbf{m}_{k-j} P^{(j-2)(k-j+1)} \\ \mathbf{p}_{j-2} &= \mathbf{p}_{j-1} P^{(j-3)} + \mathbf{p}_j P^{(j-3)2} + \mathbf{m}_1 P^{(j-3)3} + \cdots + \mathbf{m}_{k-j} P^{(j-3)(k-j+2)} \\ &\vdots \quad\quad \vdots \quad\quad \vdots \quad\quad \vdots \\ \mathbf{p}_l &= \mathbf{p}_{l+1} P^{(l-1)} + \mathbf{p}_{l+2} P^{(l-1)2} + \cdots + \mathbf{p}_j P^{(l-1)(j-l)} \cdots + \mathbf{m}_{k-j} P^{(l-1)(k-l)} \\ &\vdots \quad\quad \vdots \quad\quad \vdots \quad\quad \vdots \\ \mathbf{p}_1 &= \mathbf{p}_2 + \mathbf{p}_3 + \cdots + \mathbf{p}_j + \mathbf{m}_1 + \mathbf{m}_2 \cdots + \mathbf{m}_{k-j} \end{aligned} \quad (15)$$

or in a simplified equation as

$$\begin{aligned} \mathbf{p}_j &= \sum_{i=1}^{k-j} \mathbf{m}_i P^{(j-1)i} \\ \mathbf{p}_l &= \sum_{i=1}^{j-l} \mathbf{p}_{l+i} P^{(l-1)i} + \sum_{i=1}^{k-j} \mathbf{m}_i P^{(l-1)(j-l+i)}; 1 \le l \le j-1 \end{aligned} \quad (16)$$

There is a total of j parity subblock equations. We start from the computation of $\mathbf{p}_j$ all the way to $\mathbf{p}_1$. Notice that subblock-type encoding does not require any real multiplication due to the fact that the result of a vector multiplying with permutation matrix is nothing but cyclic-shift the vector to the right by the power of the matrix **P.**

B. *Implementation of Subblock Encoder Circuit Using Serial Structure*

The parity subblocks in Eq. (14) can be implemented in Serial or Semi-Parallel structure. Here, we discuss the serial circuit type. According to Eq.(14), the amount of shifts in each equation is determined by the power of **P** matrix and it needs to be stored in ROM. The encoder circuit consists of shift and modulo-2 addition operations as shown in Fig. 2. We first compute the parity subblock $\mathbf{p}_j$. The message subblock $\mathbf{m}_1$ is first read into the top registers, then shifted by the amount of (j-1) times to the right. It is then placed at the bottom register. Next, the subblock $\mathbf{m}_2$ is read in and shifted by (j-1) times to the right. The output is moved to the bottom and XOR with previous stored subblock. The entire process is repeated until $\mathbf{p}_j$ is fully computed. Each subblock of $\mathbf{p}_l$ is computed similarly except that the previously computed parity subblocks will be used together with message subblocks.

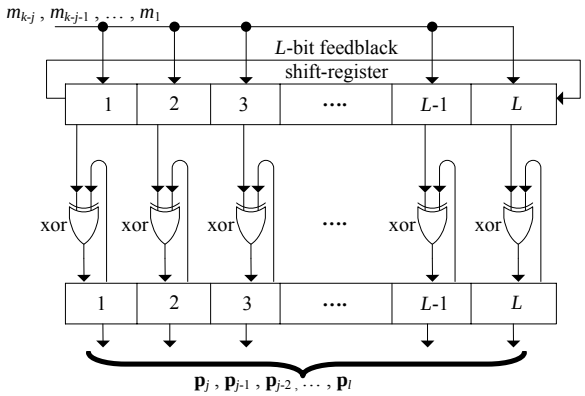

Fig. 2. Serial Encoder Circuit of Modified Array Codes

C. *Implementation of Subblock Encoder Circuit Using Semi-Parallel Structure*

To speed up the encoding process, and considering the encoding process in Eq. (15) and Eq. (16), the message subblocks are used in all equations, thus they can be shifted in advance and in Semi-Parallel, ready for the computation of higher-indexed parity subblocks as shown in Fig. 3.

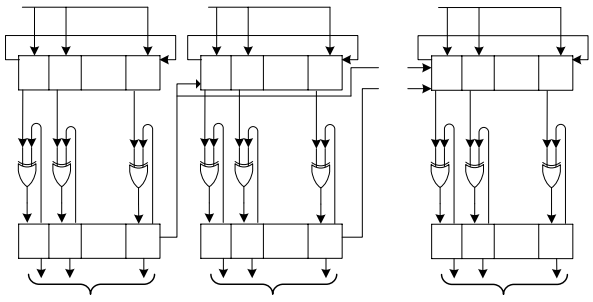

Fig. 3. Semi-Parallel Encoder Circuit of Modified Array Codes

IV. ANALYSIS RESULTS AND DISCUSSIONS

The circuit synthesis of serial and Semi-Parallel structure is performed on Quartus II with the utilized resources computed. The comparison of both designs against the direct XOR networks is illustrated in Table I.. The circuit analysis begins

with small message block size c = 361 bits and permutation matrix *P* of dimension 19x19. For this code, the complexity between Semi-Parallel circuit and direct XOR networks is similar, but for the block with large matrix *P* of dimension 43x43 and c = 1849 bits, XOR networks requires about 3 times logic elements than Semi-Parallel networks. Direct encoder circuits based on XOR Network requires much higher number of logic elements compared with subblock encoder for large message blocks. Larger message block size with larger permutation matrix size causes XOR networks to far exceed the complexity of subblock methods. In addition, direct XOR networks lack clock signal to synchronize the encoding process. For subblock encoding, serial circuits require less logic elements than the Semi-Parallel counterpart. The speed of Semi-Parallel circuit is of course faster. It is observed that Semi-Parallel encoding is 3 times faster than serial encoding circuits.

TABLE I. The Number of Required Logic Elements

Type		Quasi - Cyclic – LDPC Encoding		
Permutation Matrix	Block Size	Serial	Semi-Parallel	XOR Network
P = 19	c = 361	124	213	228
P = 29	c = 841	180	480	813
P = 37	c = 1369	236	849	1,801
P = 41	c = 1681	257	930	2,249
P = 43	c = 1849	269	1,049	3,314
P = 47	c = 2209	286	1,342	3,925
P = 59	c = 3481	359	1,978	13,001

The code rates of modified array codes analyzed here and listed in Table I ranges from 0.88 to 0.9. The high rate is suitable for many applications such as wireless/satellite communication under good conditions and high-density magnetic recording systems, for instance. The results from Table I is then plotted in Fig. 5. Notice the trend of required amount of logic elements. The direct XOR networks exhibit exponential increase as the block size goes up, while the serial subblock encoder shows linear complexity.

V. CONCLUSIONS

In this paper, we present a subblock encoder of modified array code, which is considered a type of quasi-cyclic LDPC codes suitable for high-rate applications such as magnetic recording systems and many other communication systems. The encoder equations are derived for each subblock at a time and then serial and Semi-Parallel circuit structures are presented. The circuit complexity in terms of number of logic

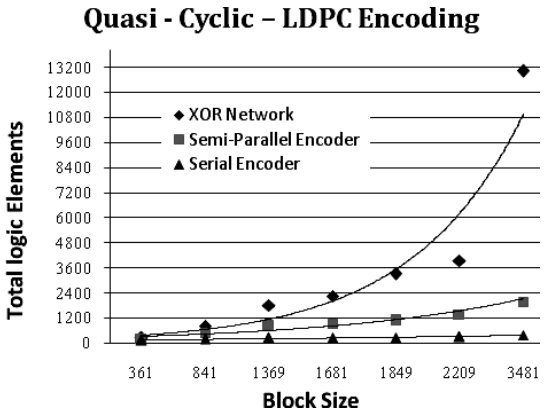

Fig. 5. The required number logic elements of direct XOR networks, Serial subblock encoder and Semi-Parallel subblock encoder

elements are compared for direct XOR networks, serial structure and Semi-Parallel structure. The direct XOR network exhibits exponential increase in complexity for large block size with lack of clock signal. The serial encoder has the lowest complexity for each message block size, but possess slower speed than the Semi-Parallel counterpart

Timing Recovery in Magnetic Recording Systems

Piya Kovintavewat

***Abstract*— Timing recovery is a crucial component in a magnetic recording channel detector. Conventional timing recovery techniques are sufficient only when operating at high signal-to-noise ratio (SNR). However, iterative error-correction codes allow reliable operation at very low SNR, where conventional techniques fail. In this paper, we summarize the timing recovery schemes based on a per-survivor processing technique that are capable of working at low SNR. Results indicate that they perform better than conventional schemes.**

I. Introduction

Timing recovery is the process of synchronizing the sampler with the received signal. Sampling at wrong times can have a devastating impact on overall system performance. Therefore, the quality of synchronization is very important in a magnetic recording channel detector.

Conventional timing recovery techniques are based on a decision-directed phase-locked loop (PLL) [1], which consists of a timing error detector (TED), a loop filter, and a voltage-controlled oscillator (VCO). They are adequate only when the operating signal-to-noise ratio (SNR) is sufficiently high. Nonetheless, recent advances in error-control coding have made it possible to communicate reliably at very low SNR, where conventional techniques fail. Many timing recovery schemes that are capable of working at low SNR have been proposed in the literature [2], [3]. In this paper, we summarize all timing recovery schemes that are based on *per-survivor processing* (PSP) [4], a technique of jointly estimating a data sequence and unknown parameters, and also investigate their performances when operating in magnetic recording systems.

This paper is organized as follows. Section II briefly describes a system model. Section III explains how conventional timing recovery works and shows its performance. Per-survivor timing recovery and per-survivor iterative timing recovery are summarized in Sections IV and V, respectively. Finally, Section VI concludes the paper.

II. System Description

We consider the perfectly equalized PR-IV channel model shown in Fig. 1, where the read-back signal can be written as

$$p(t) = \sum_k a_k h(t - kT - \tau_k) + n(t), \tag{1}$$

where $a_k \in \{\pm 1\}$ is an input data sequence with bit period T, $h(t) = q(t) - q(t-2T)$ is a PR-IV pulse, $q(t) = \sin(\pi t/T)/(\pi t/T)$ is an ideal zero-excess-bandwidth Nyquist pulse, and $n(t)$ is additive white Gaussian noise (AWGN) with two-sided power spectral density $N_0/2$. The timing offset, τ_k, is modeled as a random walk model [5] according to $\tau_{k+1} = \tau_k + w_k$, where w_k is an independent and identically distributed (*i.i.d.*) zero-mean Gaussian random variable with variance σ_w^2, and σ_w determines the severity of the timing jitter. The random walk model is chosen because of its simplicity to represent a variety of channels by changing only one parameter.

At the front-end receiver, the read-back signal $p(t)$ is filtered by a low-pass filter (LPF), whose impulse response is $q(t)/T$, to eliminate the out-of-band noise, and is sampled at time $kT + \hat{\tau}_k$, creating

$$y_k = y(kT + \hat{\tau}_k) = \sum_i a_i h(kT + \hat{\tau}_k - iT - \tau_i) + n_k, \tag{2}$$

where $\hat{\tau}_k$ is the receiver's estimate of τ_k, and n_k is *i.i.d.* zero-mean Gaussian random variable with variance $\sigma_n^2 = N_0/(2T)$.

III. Conventional Timing Recovery

Conventional timing recovery is based on a PLL. A decision-directed TED [1] is used to compute the receiver's estimate of the timing error $\epsilon_k = \tau_k - \hat{\tau}_k$, which is the misalignment between the phase of the received signal and that of the sampling clock. In this paper, we consider the well-known Mueller and Müller (M&M) TED algorithm [6], where the estimated timing error is given by

$$\hat{\epsilon}_k = \frac{3T}{16}\{y_k \hat{r}_{k-1} - y_{k-1}\hat{r}_k\}, \tag{3}$$

where $\hat{r}_k$ is the k-th estimate of the noiseless *channel output* $r_k \in \{0, \pm 2\}$. The constant $3T/16$ ensures that there is no bias at high SNR so that $E[\hat{\epsilon}|\epsilon] = \epsilon$, for small ϵ. For simplicity, we assume perfect acquisition by setting $\tau_0 = 0$. Because our model has no frequency offset component, the sampling phase offset can then be updated by a first-order PLL according to

$$\hat{\tau}_{k+1} = \hat{\tau}_k + \xi\hat{\epsilon}_k, \tag{4}$$

where ξ is a PLL gain parameter [1]. Eventually, the Viterbi detector [7] performs maximum-likelihood (ML) equalization to determine the most likely input data sequence.

As depicted in Fig. 1, a conventional receiver performs timing recovery and ML equalization separately. Therefore, the overall performance of this system (also referred to as an *uncoded* system) is mainly determined by how good conventional timing recovery is. It has been shown in [2] that conventional timing recovery does not perform well in uncoded systems when the timing error is large. Thus, the need for efficient timing recovery schemes becomes increasingly crucial. Such timing recovery schemes can be developed using per-survivor processing (PSP) techniques [4].

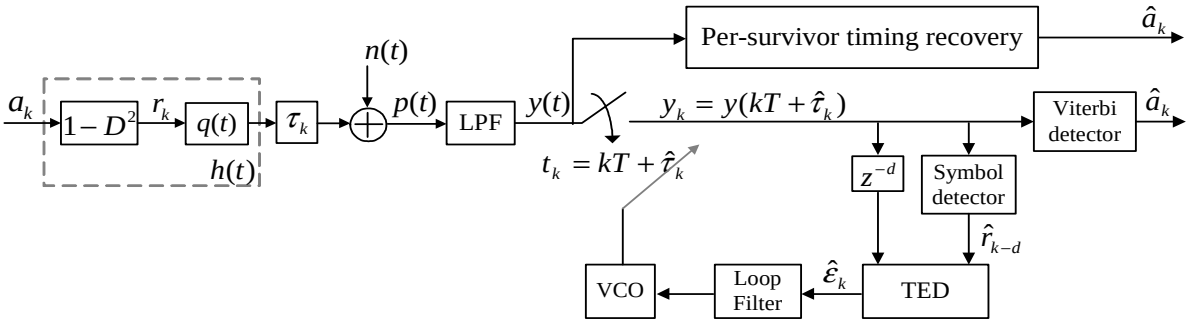

Fig. 1. The perfectly equalized PR-IV channel model with timing recovery.

IV. Per-Survivor Timing Recovery

To improve the performance of the conventional timing recovery, a reliable decision with zero decision delay can be extracted by utilizing the already-given information inside the trellis structure [7]. Specifically, each state transition in the trellis uniquely specifies a corresponding symbol. Hence, at least one state transition in each trellis stage will correspond to a correct decision. Utilizing that decision for the timing update operation will improve the performance of timing recovery.

A. Algorithm Description

With PSP, a new timing recovery scheme called *per-survivor timing recovery* was developed in [8], which jointly performs timing recovery and ML equalization, as also shown in Fig. 1. This scheme works in a similar fashion as the Viterbi algorithm does, except with an additional timing update operation. The key idea is to sample the received analog signal using different sampling phase offsets associated with each state transition. Additionally, each survivor path has its own PLL to update the sampling phase offset. In pseudocode, per-survivor timing recovery can be summarized as follows, where L is the length of an input sequence, and Q is the total number of trellis states in one stage. For details, a reader can refer to [8].

```
Initialize the sampling phase offset and
the path metric
for k = 1 : L (each time instant)
    for q = 1 : Q (each trellis state)
      sample the waveform y(t) using a PLL
      and the sampling phase offset, τ̂_k,
      associated with the starting state
      to get samples {y_k}
      compute the branch metrics
      compute the path metric
      update the survivor path
      update the next sampling phase
      offset, τ̂_{k+1}, using the information
      obtained from the survivor path that
      leads to state q
    end
end
decode a data sequence from the survivor
path that has the minimum path metric
```

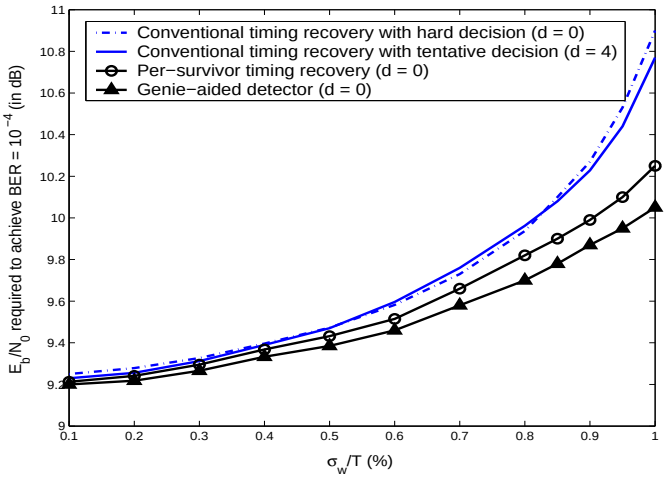

Fig. 2. Performance comparison of different timing recovery schemes [8].

B. Performance Results

Fig. 2 compares the performance of different timing recovery schemes by plotting the E_b/N_0 (in dB) requirement for bit-error rate (BER) 10^{-4} as a function of σ_w/T's, where a parameter d in the parenthesis denotes the total delay in the timing loop. The curve labeled "genie-aided detector" represents conventional timing recovery whose PLL has access to all correct decisions, thus serving as a lower bound for a timing recovery scheme that is based on a PLL. The tentative decision is obtained from the Viterbi detector with a (short) decision delay of $d = 4$. This is done by choosing the *best* survivor path at each time instant, and then the *tentative decision*, $\hat{r}_{k-d}$, is found by moving d steps backward along that survivor path.

Clearly, per-survivor timing recovery performs better than conventional timing recovery, especially when σ_w/T is large. This can be intuitively explained as follows. At each time instant, at least one state transition in each trellis stage will correspond to the correct decision. Using that decision to perform the timing update operation will help improve timing recovery performance. In other words, the PLL is *fully trained* if the correct path is chosen. By following this idea for an entire received signal, the overall performance is improved.

V. Per-Survivor Iterative Timing Recovery

Iterative error-control codes (ECCs) allow reliable operation at low SNR because of their large coding gains [9]. This means that timing recovery must also function at low SNR. A conventional receiver performs timing recovery and error-correction decoding separately. Specifically, conventional timing recovery ignores the presence of ECCs. Thus, it fails to work properly at low SNR.

Theoretically, joint ML estimation of timing offsets and message bits, which will jointly perform timing recovery, equalization, and decoding, is a preferred method of synchronization [10] but its complexity is huge. A solution based on the expectation-maximization (EM) algorithm [11] is also complex. Fortunately, a solution to this problem with complexity comparable to the conventional receiver has been proposed in [12], which will be referred to as *the NBM scheme*. It is realized by embedding the timing recovery step inside the turbo equalizer so as to perform timing recovery, equalization, and decoding jointly. Nonetheless, this scheme requires a large number of turbo iterations to provide a good performance even with a cycle slip [1] detection and correction algorithm as used in [12], especially when timing error is large.

To improve the performance of the NBM scheme, an iterative timing recovery scheme called *per-survivor iterative timing recovery* has been proposed in [13]. It is realized by first applying the per-survivor concept to the Bahl, Cocke, Jelinek, and Raviv (BCJR) algorithm [14], resulting in PSP-BCJR. Then, per-survivor iterative timing recovery iteratively exchanges soft information between PSP-BCJR and a soft-in soft-out (SISO) decoder.

Consider the *coded* PR-IV channel model shown in Fig. 3. The message bits $\{x_k\}$ are encoded by a serial concatenation of an error-correction encoder, an s-random interleaver [9] (i.e., the π block), and a $1/(1 \oplus D^2)$ precoder. The read-back signal $p(t)$ expressed as given in (1) is filtered by an LPF and is sampled at time $kT + \hat{\tau}_k$, creating y_k according to (2).

We also assume perfect acquisition. Because our model has no frequency offset component, the sampling phase offset can then be updated by a first-order PLL according to

$$\hat{\tau}_{k+1} = \hat{\tau}_k + \xi \frac{3T}{16}\{y_k \tilde{r}_{k-1} - y_{k-1}\tilde{r}_k\}, \tag{5}$$

where $\tilde{r}_k$ is the k-th *soft estimate* of the *channel output* $r_k \in \{0, \pm 2\}$ given by [12]

$$\tilde{r}_k = E[r_k|y_k] = \frac{2\sinh(2y_k/\sigma_n^2)}{\cosh(2y_k/\sigma_n^2) + e^{2/\sigma_n^2}}. \tag{6}$$

In the conventional receiver, conventional timing recovery is followed by a turbo equalizer [15] (see Fig. 3), which iteratively exchanges soft information between the SISO equalizer for the precoded PR-IV channel and the SISO decoder.

A. Algorithm Description

PSP-BCJR [13] is developed by embedding the timing recovery process inside the BCJR equalizer so as to perform timing recovery and ML equalization jointly. It works in a similar manner as per-survivor timing recovery does. Nevertheless, we update the timing estimate at each state based on the incoming branch that contributes the most to the state information. In pseudocode, PSP-BCJR can be summarized as follows.

```
FORWARD RECURSION:
Initialize the forward sampling phase
offset and the forward state information
for k = 1 : L (each time instant)
    for q = 1 : Q (each trellis state)
      sample the waveform y(t) using a PLL
      and the forward sampling phase
      offset, τ̂_k, associated with the
      starting state to get samples {y_k}
      compute the BCJR branch metrics
      compute the forward state
      information
      update the next forward sampling
      phase offset, τ̂_{k+1}, based on the most
      likely incoming branch that leads to
      state q
    end
end

BACKWARD RECURSION:
Initialize the backward sampling phase
offset and the backward state information
for k = L : 1 (each time instant)
    for p = 1 : Q (each trellis state)
      sample the waveform y(t) using a PLL
      and the backward sampling phase
      offset, τ̂^b_{k+1}, associated with the
      starting state to get samples {y^b_k}
      compute the BCJR branch metrics
      compute the backward state
      information
      update the next backward sampling
      phase offset, τ̂^b_k, based on the most
      likely incoming branch that leads to
      state p
    end
    compute a posteriori log-likelihood
    ratio (LLR) of the input bit, λ_k,
    using the forward and the backward
    state information
end
```

B. Performance Results

The per-survivor iterative timing recovery scheme is easily obtained by discarding the front-end PLL in Fig. 3 and replacing the BCJR equalizer with PSP-BCJR.

Consider a rate-8/9 system in which a block of 3636 message bits is encoded by a rate-1/2 recursive systematic convolutional encoder with a generator polynomial $[1, \frac{1 \oplus D \oplus D^3 \oplus D^4}{1 \oplus D \oplus D^4}]$, and then punctured to a block length of 4095 bits by retaining only every the eighth parity bit. The punctured sequence passes through an s-random interleaver with $s = 16$ to obtain an interleaved sequence of b_k. Both the SISO equalizer and the SISO decoder are implemented based on BCJR. We use the PLL gain parameter designed based on minimizing the RMS

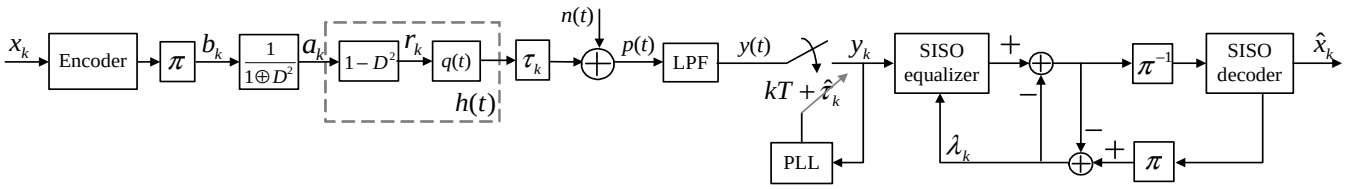

Fig. 3. A coded PR-IV channel model.

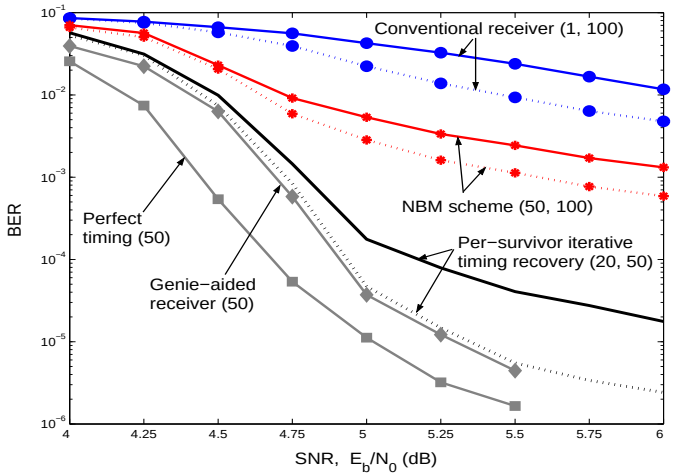

Fig. 4. Performance comparison with $\sigma_w/T = 1\%$ [13].

timing error, $\sigma_\epsilon = \sqrt{E[(\tau_k - \hat{\tau}_k)^2]}$, at $E_b/N_0 = 5$ dB. Each BER point was computed using as many data packets as possible until at least 100 sectors in error were collected at the 100-th iteration.

Fig. 4 compares the BER performance of different schemes for the system with a severe random walk parameter $\sigma_w/T = 1\%$, which implies a high probability of occurrence of a cycle slip. Note that the number inside the parenthesis in Fig. 4 indicates the total number of iterations used to generate each curve. The curve labeled "Perfect timing" represents the conventional receiver that uses $\hat{\tau}_k = \tau_k$ to sample $y(t)$. Clearly, per-survivor iterative timing recovery outperforms both the conventional receiver and the NBM scheme. This is because per-survivor iterative timing recovery can correct a cycle slip much more efficiently than the NBM scheme [13]. In addition, it performs similar to the genie-aided receiver and loses approximately a 0.35 dB relative to the system with perfect timing at BER = 10^{-5}.

VI. Conclusion

We summarized the timing recovery schemes that are based on per-survivor processing. It is clear that per-survivor timing recovery can perform better than conventional timing recovery, especially when the SNR is low and the timing error is large. By exploiting the presence of error-correction codes, per-survivor iterative timing recovery can perform even better than per-survivor timing recovery, but at the expense of increased complexity and the requirement of batch processing.

Simulation results has illustrated that per-survivor iterative timing recovery performs better than other iterative timing recovery schemes, especially when the timing error is severe. This is because it can correct a cycle slip much more efficiently than other schemes. Additionally, Kovintavewat *et al* [16] have proposed a reduced-complexity version of per-survivor iterative timing recovery, which has been shown to perform better than (full-complexity) per-survivor iterative timing recovery at low to moderate complexity regime.

***Abstract*- In this paper, we propose a new algorithm for ECG classification that is less sensitive to the morphological variation of ECG. In the feature extraction process, the multiresolution wavelet transform and autoregressive modelling (AR) are applied together to obtain the feature vectors of ECG data. For the classifier, we have applied the fisher's discriminant and fuzzy c-mean working as hierarchical clustering with a top-down strategy. The results of experiments have confirmed good efficiency of the proposed algorithm. The investigations show that the method may find useful in practical applications for the classification of different type heartbeats.**

I. INTRODUCTION

The electrocardiogram (ECG) is a graphic record of the direction and magnitude of the electrical activity that is generated by depolarization and repolarization of the atria and ventricles. One cardiac cycle in an ECG signal consists of the P-QRS-T waves. The analysis of the ECG has been widely used for diagnosing many cardiac diseases. The most difficult problem faced by today's automatic ECG analysis is the large variation in the morphologies of ECG waveforms, not only of different patients or patient groups but also within the same patient. The ECG waveforms may differ for the same patient to such extend that they are unlike to each other and at the same time alike for different types of beats. This is the main reason that the beat classifier, performing well on the training data behaves badly, when presented with different patients ECG waveforms.

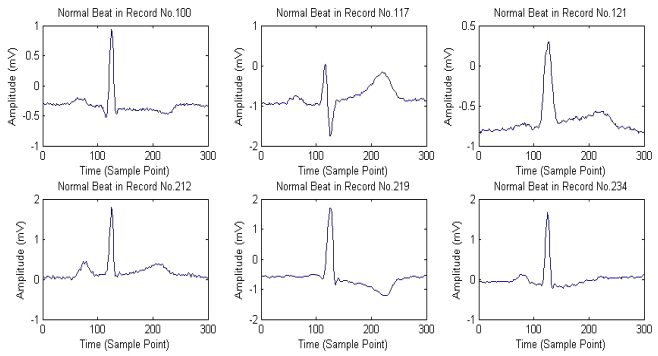

Figure 1. Normal ECG beat type in record No. 100, 117, 121, 212, 219, and 234.

Several algorithms have been developed in the literature for the detection and classification of ECG beats [1], [2], [3], [4] which various algorithms used ECG beat in the same class from only one person or record for training and testing those systems, in fact it may be unable to use in real situation due to above-mentioned reason. In this paper, we propose a new algorithm for ECG classification that is not complex model but gave a good efficiency. Fig. 1 represents the difference of ECG beat in the same class.

In the remainder of this paper, an overview of preprocessing algorithm for ECG data is firstly presented. Then, the feature extraction through the wavelet transform and autoregressive modelling (AR) is described in the next section. After that, in the classification, the Fisher's discriminant and fuzzy c-mean are presented. The training and testing process for each class of ECG are given next. Finally, the work is concluded and the suggestion for the future.

II. ECG DATA AND PREPROCESS

In this paper, ECG signal from Modified Limb Lead II (MLII) are chosen for processing due to they mostly found in the database. The recordings are digitized at 360 samples per second per channel. Each record has its respective annotation file that indicates the class of the heartbeat. We select different abnormal QRS complexes from several records. It is noticed that, there are six types of QRS complexes appeared frequently in the database. Therefore, we mainly deal with these six types heartbeats which include normal beat (NORMAL), left bundle branch block beat (LBBB), right bundle branch block beat (RBBB), paced beat (PACE), premature ventricular contraction (PVC) and atrial premature contraction (APC).

In the preprocessing phase, the continuous ECG signals must be separated into many segments which contain only one heartbeat. The extracted data of ECG complexes are centered around R peak, we have selected the segment of 250ms before the R peak point and 400ms after that with the R peak point is the 90th point. The R peak is detected using the Pan and Tompkins algorithm [5]. Thus, each segment must contain one ECG heartbeat. Fig. 2 shows typical waveforms of the six types of ECG segments described above.

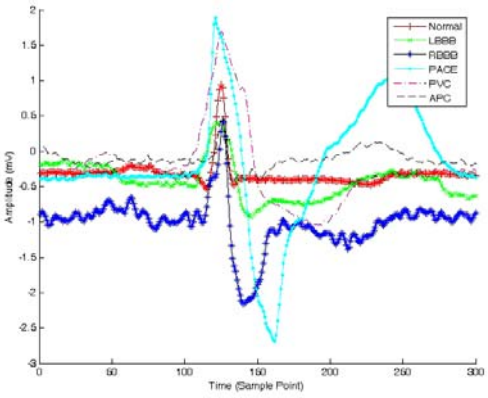

Figure 2. Typical waveforms of the six types of ECG segment.

III. FEATURE EXTRACTION

The recognition of heart rhythms requires generation of feature vectors which represents the original ECG segment. A good recognition system should depend on the features representing the ECG signals in such a way that the differences among the ECG waveforms are suppressed for the waveforms of the same type, while the differences should be emphasized for the waveforms of belonging to different types of heartbeats. We perform recognition process of heart rhythms on the single heartbeat of the ECG, proposing the description or representation by wavelet transform and AR model.

A. Wavelet Transform

From the wavelet multiresolution analysis properties [4], [6], and for any function $f(k) \in L^2(R)$, $f(k)$ can be expressed by the approximation and detail wavelet coefficients

$$f(x) = \sum_n a_{J,n}\phi_{J,n}(k) + \sum_{j=j_0}^{J}\sum_n d_{j,n}\psi_{j,n}(k) \qquad J > j_0, \qquad (1)$$

where $a_{J,n}$ are the approximation coefficients at scale level J, $\phi_{J,n}(k)$ is the scaling function, $d_{j,n}$ are the detail coefficients at scale level j, $\psi_{j,n}(k)$ is the wavelet function, and j_0 is the finest decomposed scale level. For simplicity, the wavelet coefficients will be written without the suffix n (e.g., $a_{j,n}$ and $d_{j,n}$ will be denoted as a_j and d_j, respectively). More detailed explanations of the wavelet transform theory and its applications are found in [6], [7], [8], and [9].

The selection of appropriate wavelet and the number of decomposition level are very important in analysis of signals using the WT. The number of decomposition levels is chosen based on the dominant frequency components of the signal. The level is chosen such that those parts of the signal that correlate well with the frequencies required for classification of the signal are retained in the wavelet coefficients. Usually, tests are performed with different types of wavelets and the one which gives maximum efficiency is selected for the particular application. Therefore, the wavelet used in this work is Daubechies wavelet of order 8, the chosen number of decomposition levels is 4. Thus, the ECG signals are decomposed into the details d_1 -d_4 and one approximation a_4.

Feature selection is also very important component, For each heartbeat, the detail wavelet coefficient d_1 are usually noise signals that must be eliminated and d_2, d_3, d_4 represent high frequency parts of the ECG signal. Since the approximation wavelet coefficients a_4 represent the main feature of each heartbeat, then we choose a_4 to be the feature of each heartbeat. For one heartbeat, the original signal contains 300 points, and a_4 contains 32 points. Fig. 3 shows the wavelet feature extraction of some normal heartbeats in record No. 100.

B. Autoregressive Modelling

In an AR process of order p, the signal $x[n]$ at time instant nth may be represented as a linear combination of p previous values of the same signal. Specifically, the process is modeled as

$$x[n] = \sum_{i=1}^{p} a[i]x[n-i] + e[n] \qquad (2)$$

where $a[i]$ is the ith coefficient of the AR model, $e[n]$ is a white noise with mean zero, and p is the AR order. Various methods are currently used to estimate the coefficients of the autoregressive process. The criterion used to evaluate the model order selection in this work is ARfit method [10]. Eventually, we select 4-order AR model to represent each heartbeat of ECG signals.

C. Generation of The Feature Vectors

The feature vector is composed of wavelet coefficients and AR coefficients. For each ECG heartbeat, the original signal is a vector of 300 dimensions $\{y_1, y_2, ..., y_{300}\}$. The wavelet coefficient for this is a vector of 32 dimensions $\{w_1, w_2, ..., w_{32}\}$, together with the AR coefficient vector of 4 dimensions

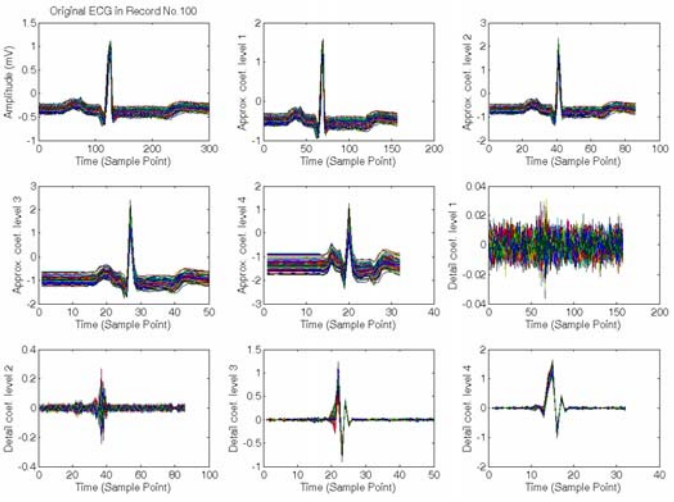

Figure 3. Wavelet transformation of normal heartbeats in record No.100.

$\{a_1, a_2, a_3, a_4\}$. Then wavelet coefficients and AR coefficients can be concatenated together to form the feature vector $\{w_1, w_2, ..., w_{32}, a_1, a_2, a_3, a_4\}$ for classification.

IV. ECG CLASSIFICATION

A. Fisher's Discriminant

Fisher's Linear Discriminant (FLD) [11], [12] is a widely used method for feature extraction and dimensionality reduction in pattern recognition. Fisher's idea is based on seeking projection direction $\boldsymbol{W}$ that separates the class means well (when projected onto the direction $\boldsymbol{W}$) while achieving a small variance around these means. Mathematically, FLD selects the projection $\boldsymbol{W}$ in such a way that the ratio of the between-class scatter matrix and the within-class scatter matrix is maximized.

For a *c*-class problem, the between-class scatter matrix is defined as

$$\mathbf{S}_B = \sum_{i=1}^{c} N_i (\boldsymbol{\mu}_i - \boldsymbol{\mu})(\boldsymbol{\mu}_i - \boldsymbol{\mu})^T \tag{3}$$

and the within-class scatter matrix as

$$\mathbf{S}_W = \sum_{i=1}^{c} \sum_{\mathbf{x}_k \in X_i} (\mathbf{x}_k - \boldsymbol{\mu}_i)(\mathbf{x}_k - \boldsymbol{\mu}_i)^T \tag{4}$$

where $\boldsymbol{\mu}_i$ is the mean samples of class $\boldsymbol{X}_i$, $\boldsymbol{\mu}$ is the mean sample of all classes, and N_i is the number of samples in class $\boldsymbol{X}_i$. If $\mathbf{S}_W$ is nonsingular, the optimal projection $\boldsymbol{W}_{opt}$ is chosen as a matrix with its orthonormal columns that maximizes the ratio of the determinant of between-class scatter matrix to the determinant of within-class scatter matrix obtained from the projected samples, i.e.,

$$\begin{aligned} \boldsymbol{W}_{opt} &= \arg\max_{\boldsymbol{W}} \frac{\left|\boldsymbol{W}^T \mathbf{S}_B \boldsymbol{W}\right|}{\left|\boldsymbol{W}^T \mathbf{S}_W \boldsymbol{W}\right|} \\ &= \left[\mathbf{w}_1 \quad \mathbf{w}_2 \quad ... \quad \mathbf{w}_m\right] \end{aligned} \tag{5}$$

where $\left\{\mathbf{w}_i \,|\, i = 1, 2, ..., m\right\}$ is the set of generalized eigenvectors of $\mathbf{S}_B$ and $\mathbf{S}_W$ corresponding to the *m* largest generalized eigenvalues $\left\{\lambda_i \,|\, i = 1, 2, ..., m\right\}$, where

$$\mathbf{S}_B \mathbf{w}_i = \lambda_i \mathbf{S}_W \mathbf{w}_i , \qquad i = 1, 2, ..., m \tag{6}$$

B. Fuzzy c-mean

Fuzzy c-means (FCM) [2], [13] is a data clustering technique wherein each data point belongs to a cluster to some degree specified by a membership grade.

Assume that the vectors representing the data under classification are denoted by $\mathbf{x}_k$ for $k = 1, 2, ..., p$ where $\mathbf{x}_k = \left[x_{k1}, x_{k2}, ..., x_{kN}\right]^T \in R^N$. Let these vectors be partitioned into *c* clusters, each represented by the center vector $\mathbf{c}_i = \left[c_{i1}, c_{i2}, ..., c_{iN}\right]^T$. Denote $\mathbf{U} \in R^{c \times p}$, the partition matrix of the elements u_{ij} represents the membership degrees of the data vector $\mathbf{x}_j (j = 1, 2, ..., p)$ in the *i*th cluster $(i = 1, 2, ..., c)$. The fuzzy clustering algorithms will search for the partition matrix and cluster centers such that the objective function *E* is minimized

$$E = \sum_{i=1}^{c} \sum_{j=1}^{p} u_{ij}^m d^2(\mathbf{x}_j, \mathbf{c}_i) \tag{7}$$

subject to

$$\sum_{i=1}^{c} u_{ij} = 1 \tag{8}$$

for $(j = 1, 2, ..., p)$. The parameter *m* controls the fuzziness of the clusters (typically *m*=2). The function $d(\mathbf{x}_j, \mathbf{c}_i)$ measures the distance between the data vector $\mathbf{x}_j$ and the center $\mathbf{c}_i$ of the *i*th cluster.

$$d^2(\mathbf{x}_j, \mathbf{c}_i) = (\mathbf{x}_j - \mathbf{c}_i)^T (\mathbf{x}_j - \mathbf{c}_i) \tag{9}$$

At the given data vectors $\mathbf{x}_j$, choose the number of clusters *c*, the weighting coefficient *m*, and the termination tolerance ε . Initialize the partition matrix $\mathbf{U}$ randomly in such a way that conditions $\sum_{i=1}^{c} u_{ij} = 1$ for all vectors $\mathbf{x}_j$ are satisfied. Then iterate through the following steps.

1) Determine the cluster prototypes $\mathbf{c}_i (i = 1, 2, ..., c)$

$$\mathbf{c}_i = \frac{\sum_{j=1}^{p} u_{ij}^m \mathbf{x}_j}{\sum_{j=1}^{p} u_{ij}^m} \tag{10}$$

2) Compute the distances $d_{ij}^2 (i = 1, 2, ...,c$ and $j = 1, 2, ...,p)$ between the input vector $\mathbf{x}_j$ and the cluster centers $\mathbf{c}_i$ using (9).

3) Update the partition matrix u_{ij} entries $(i = 1, 2, ...,c$ and $j = 1, 2, ...,p)$

$$u_{ij} = \frac{1}{\sum_{k=1}^{c} \left(\frac{d_{ij}}{d_{kj}}\right)^{2/(m-1)}} \tag{11}$$

If $d_{ij} = 0$ for some $i = I$, take $u_{Ij} = 1$ and $u_{ij} = 0$ for $i \neq I$, iterate until $\left\|\mathbf{U}^l - \mathbf{U}^{l-1}\right\| \leq \varepsilon$ for two succeeding iterations.

V. EXPERIMENT AND RESULTS

In the experiment, twenty-two difference patients taken from MIT-BIH arrhythmia database [14] have been considered, patients numbered 100, 107, 109, 111, 116, 117, 118, 119, 124, 200, 201, 207, 208, 212, 213, 217, 219, 221,

228, 231, 232, and 234. The ECG beats being classified are separated into two groups: one used in the learning and the other used in the testing mode, each feature vector of ECG beats is a vector of 36 dimensions from the feature extraction process described above.

A. Training Process

In the training process, the ECG feature vectors prepared for the training are processed by the Fisher's discriminant technique in order to seek new basis vectors $\{\mathbf{w}_i \,|\, i = 1, 2, ..., m\}$. After that each of the feature vectors is projected onto the new bases corresponding to *m* largest generalized eigenvalues $\{\lambda_i \,|\, i = 1, 2, ..., m\}$. The number of the *m* new bases is obtained from the number of vectors that give the best discriminated class when using FCM. From the experiment, six types of ECG according to Normal, RBBB, APC, LBBB, PVC, and PACE type are trained. However, by the FCM, only four clusters give the best separation in the first place. Therefore the process should be multistep clustering based on top-down strategy called hierarchical clustering.

In the first step, the FCM roughly separates all ECG data into four destined clusters such that Normal, RBBB, and APC are in the same class and LBBB, PVC, and PACE belong to the individual class respectively. In this step, the ECG feature vectors are projected onto 3 new bases by the Fisher's discrimination.

In the next step, Normal, RBBB, and APC beat types are further separated by projecting onto 2 new basis vectors via the Fisher's discrimination. In this second, the FCM will separate these three classes into four sub-clusters. Where the RBBB type composes of two clusters due to the distribution in this class.

B. Testing Process

In the testing process, the tested feature vectors are projected onto the 3 same bases as done in the training mode based on Fisher's discrimination technique. Then, the distances between the unknown feature vectors (in 3 dimensions) and the centers of each cluster (4 clusters) are calculated to classify them into the rough class. If they are in the mixed class (Normal, RBBB, and APC), they must be further classified by Fisher's discrimination and FCM again, otherwise the vectors belong to the single class.

TABLE I
EXPERIMENTAL RESULTS

ECG Beat Type	Training			Testing		
	Number	Correctly beat	Accuracy (%)	Number	Correctly beat	Accuracy (%)
Normal	1000	981	98.1	1000	978	97.8
LBBB	1000	981	98.1	1000	993	99.3
RBBB	1000	985	98.5	1000	942	94.2
APC	1000	951	95.1	500	489	97.8
PVC	1000	969	96.9	1000	942	94.2
PACE	1000	965	96.5	1000	956	95.6
Total	**6000**	**5832**	**97.20**	**5500**	**5300**	**96.36**

It is interesting to compare the obtained figures with the results presented in the literature by using different methods of beat classification. The comparison of proposed method with the different methods in [2] indicates high efficiency of the proposed approach.

VI. CONCLUSIONS

The new technique of ECG classification utilizing the multiresolution wavelet transform, autoregressive modelling, Fisher's discrimination, and fuzzy c-mean has been proposed in this paper. The feature sets have been carefully chosen to provide enough information and good accuracy. The wavelet transform is used to extract the ECG waveform features. Simultaneously, autoregressive modelling (AR) is also applied to obtain the temporal structures. The Fisher's discrimination and fuzzy c-mean are used to reduce the dimensions of feature vector and to classify the ECG beats respectively. The proposed algorithm is less sensitive to the morphological variation of ECG. The results of experiments have confirmed good efficiency of the proposed approach and also give good accuracy.

***Abstract* - This paper proposed a hybrid method for an ECG data compression method is based discrete wavelet transform (DWT). In order to increase the compression ratio, the preprocessing process is implemented by period detection and normalization of ECG wavelet coefficients. Then Run-Length Coding (RLE) is applied to each residual sequence obtained after average beat subtraction and threshold the differencing of residual data afterward. The difference between the actual period and the mean beat period for each beat are initially transmitted together with the standard mean beat to the decoder. At the decoder, original period of each beat are first recovered before re-ordered the wavelet coefficients and inverse wavelet transform is retrieved the reconstructed ECG signal. This experiment show the compression performance of the proposed method refer to the MIT/BIH arrhythmia database and the regular record 117 and the QRS complex record 203 have been employed to this experiment. The obtained of compression ratio is more than 20 with the percent root-mean-square difference (PRD) less than 1.5%.**

I. INTRODUCTION

Electrocardiogram (ECG) data provide cardiologists with essential information to diagnose heart disease in a patient. In an ambulatory monitoring system, the volume of ECG data is necessary large, as along period of time is required in order to gather enough information about the patient. As an example, with the sampling rate of 360 Hz, 11 bits/sample data resolution, a 24 hour record requires about 43 Mbytes per channel. Therefore, an effective data compression scheme for ECG signals is required in many practical applications including: ECG data storage, ambulatory monitoring system, ECG data transmission over telephone line or digital telephone network. Since it is often necessary to store or transmit ECG, efficient compression techniques are important to reduce transmission time or required storage capacity.

Previous ECG data compression techniques have been reported in the literature and include direct time-domain techniques [1], transform-domain techniques [2]–[4], average beat subtraction [8], and different modeling methods [5]-[7]. The main goal of the methods presented here is to achieve sufficiently high compression ratios (CR) without affecting the diagnostic characteristics of the ECG signals. In fact, the Simulation result from MATLAB presented here are based on different compression methodologies using the discrete wavelet transform (DWT) concept, with an enhanced coding scheme based on the combination of DWT, average beat subtraction, Threshold and Run-Length Coding. However, the main emphasis in this paper will study the compression characteristics of both regular ECG and complex QRS record.

II. COMPRESSION ALGORITHM

In this paper we propose an ECG compression method based on average beat subtraction of DWT coefficients and Run-Length coding. The block diagram of this method is shown in Fig. 1 and 2. This method initiates originally from the work of Hamilton and Tompkins, [8] "Compression of ambulatory ECG by average beat subtraction and residual differencing," and Ramakrishnan and Saha [9], "ECG data coding by wavelet based linear prediction". This proposed technique is also follows similar steps as in [8], [9], but it is more simple, provides higher CR and achieved with nearly constant ECG reconstruction error.

Fig.1 Show block diagram of compression process. When a beat is detected an average beat is aligned with that beat and subtracted by from the signal. The detected beat is then used to update the average beat estimate. After beat subtraction the residual signal is differenced. The differenced signal is Run-Length Coding and store along with the record of the beat location.

Fig.2 Show a block diagram of the operations required for decompression. The residual signal is decoded and first summed to undo the first differencing. The average beat is added to the residual signal as indicated by the stored beat locations. As beat reconstructed they are used the average beat estimate. As long as the average beat is initially equal to the average beat used in compression.

A. Discrete Wavelet transforms.

In this research method the first order of Discrete wavelet transform (DWT) express by (1), (2) and (3) is respectively determination of a scaling coefficient and Wavelet coefficient at a scale of *j-1* where $c_j(m)$ is a set of an input signal. The set of a scaling coefficient is denoted by $c_{j-1}(k)$ and the wavelet coefficient is denoting by $d_{j-1}(k)$. h_0 and h_1 are the filter coefficient.

$$c_{j-1}(k) = \sum h_0(m-2k)c_j(m) \tag{1}$$

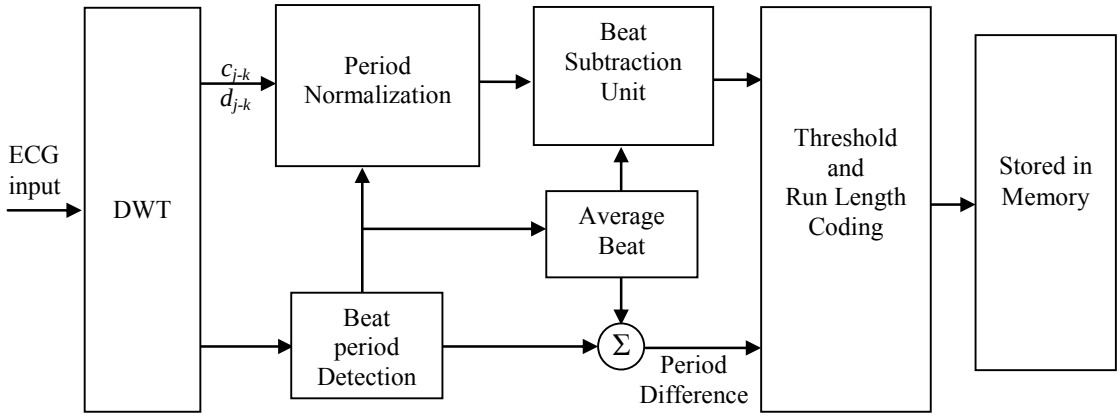

Fig.1 Block diagram of Compression process

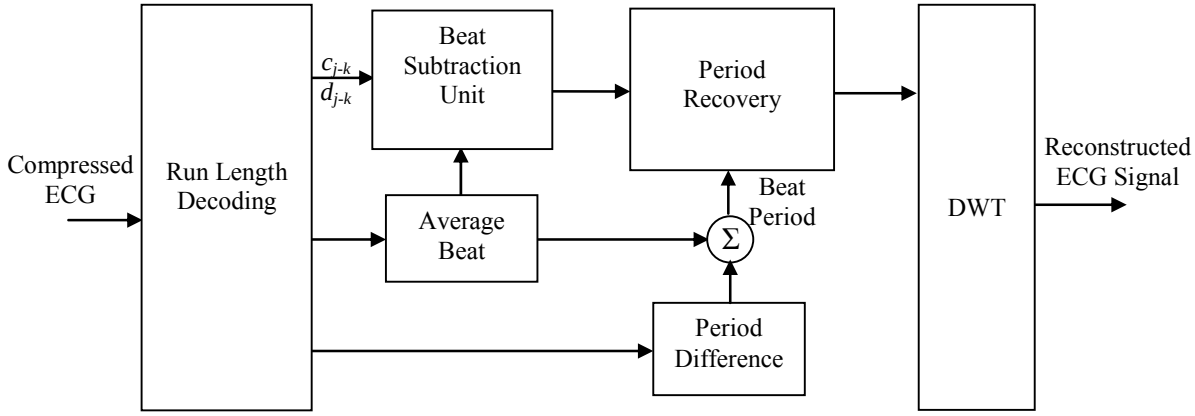

Fig.2 Block diagram of Decompression process

$$d_{j-1}(k) = \sum h_1(m-2k)c_j(m) \tag{2}$$

$$\begin{bmatrix} c_{j-1}(k) \\ d_{j-1}(k) \end{bmatrix} = \begin{bmatrix} h_0(n) \\ h_1(n) \end{bmatrix} \left[c_j(m) \right] \tag{3}$$

B. Period detection and Period Normalization

For period detection we define a cycle as the signal from one wave to the next. We used the technique reported in [8]. In this algorithm, the ECG is Band-pass filtered, differentiated, and squared. The squared signal is over a 150ms window. A period detection occurs when a peak is detected in the process signal which exceeds a variable detection threshold based on the previous detections and noise peaks.

For delineating cycles, we normalize the period of each isolated beat by up-sampled techniques and added the appropriate constant sampled to each individual beat. This converts the beats of differing periods into beats of a constant period, thus eliminating the effect of heart rate variability. The fixed length of the cycles is selected based on the maximum possible period of interval cardiac cycle.

C. Beat subtraction.

The ECG signal is generally composed of the number of beats repeated at fairly regular intervals. Since many of the beats are markedly similar. Intuitively this method should compress the signal by subtracting an average beat with individual period normalized beat signal. And the average beat or standard beat is estimated from mean value of 7 initial cycles of the ECG data. This value is initially sent to the decoder. During encoding, the difference between the actual period of a cycle and the average beat period is also transmitted.

D. Residual Threshold and Run-Length coding.

In this state, both residual of Approximation and Detail coefficients obtained from the subtraction process are needed to threshold before Run-Length coding. Due to this experiment PRD is limited to low values in order to guarantee preservation of clinically important features of the ECG waveform.

This experiment is proposed techniques based on selection threshold index (Δ) of the residual DWT coefficients of different beats between average beat and individual normalized ECG beat. It has been observed that Only ±50% of the maximum amplitude of residual DWT coefficients in the

region of Δ (which is a minor difference) can be set equal to zero, and the residual coefficient outside the region of Δ (which is a major difference) is still remain (see Fig. 3), because these coefficients are necessary for a negligible error in the reconstruction procedure of any significant structural information of the ECG beat. Then Run-Length Coding procedure is performed across the residual of Approximation and Detail coefficient. As a result, only the sequences of data and zero value elements of the DWT coefficients is transmitted or stored. In the decoder section, the inverse DWT (IDWT) is performed on the regained DWT coefficients and after following a period recovery procedure, The ECG signal is reconstructed.

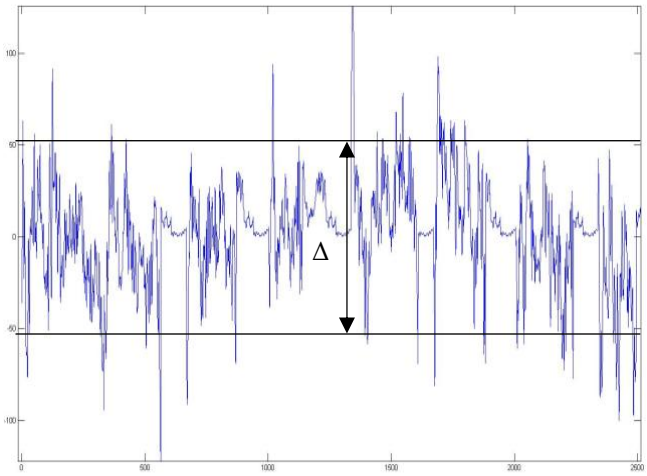

Fig.3 Threshold index selection of residual DWT coefficient of beat difference.

III. EXPERIMENTAL RESULT AND ANALYSIS

Most of the reported techniques are analysis the system based compression performance, and then compression ratio (CR) is defined as the ratio between the number of bits in the original signal and the number of bits used in reconstructed signal (4).

$$CR = \frac{x(i)}{x'(i)} \tag{4}$$

Let *x(i)*, and *x'(i)*, represent the values of the samples of the original and reconstructed signal, respectively. The perfect of reconstruction factor is frequently measured by the percent root-mean-square difference (PRD). And then, PRD factor is defined as (5).

$$PRD = \sqrt{\frac{\sum_{i=0}^{N-1}\left(x(i)-x'(i)\right)^2}{\sum_{i=0}^{N-1}x^2(i)}} \times 100 \tag{5}$$

TABLE I
Comparison of CR and PRD between the differences ECG MIT-BIH records

THRESHOLD INDEX (Δ)		40%	60%	80%	100%
MIT 203	CR	2.97	9.1	22.83	34.25
	PRD	4.3819	4.8908	5.1727	5.2285
MIT 117	CR	4	17.1	25.7	50.1
	PRD	1.447	1.378	1.3712	1.3431

The algorithmic approaches in this paper were implemented on a MATLAB-7.1. The methods were tested on abnormal ECG data from the MIT-BIH arrhythmia database files: (mit117, mit203 with sampling frequency 360 Hz).

The results in table I. shown the comparative performance results of CR and PRD values of the two ECG records to the Threshold index, which is based on the section of threshold index (Δ). In case of the original signal is uniform (as mit117) the possibility dropped the amplitude in the region of Δ equal to zero is allowed up to 100%, and without increase of any reconstruction error, and the factor of compression Ratio is increased. However, the QRS complex format (mit203) the possibility dropped is allowed only up to 50%, as the result format of reconstructed ECG is still remaining the original one, with increasing of a small reconstruction error, and the factor of Compression Ratio is increased up to 8:1.

According to the result listed in table 2, shown the overall analysis of the compression performance refer to equation (4) (this analysis of CR factor is not included size of bits transmitted the average beat of the original and Period difference, which is initially send to the Decoder ended). This proposed method is gained the improvement on the coding performance in term of CR and PRD over some resent methods including Wavelet-based pattern matching scheme [1], WHOSC [7], SPIHT [4], and so on.

TABLE II
The Maximum performance (CR and PRD) of the proposed method is compared with some recent algorithms.

Method	Proposed Method	Pattern Matching	WHOSC	SPIHT
Signal	MIT_BIH 117	MIT_BIH 117	MIT_BIH 117	MIT_BIH 117
CR	50.1	21.7	15.8	8
PRD%	1.34	1.76	1.74	1.18

As the results of the experiment of two ECG signals (mit117 and mit203) are shown in Fig.5 and Fig.6 respectively. Considering the figure 5, a first 6000 sample Database of record mit117 is used as the input of this system. And these results depicted that at a maximum CR of 50:1 is achieved with a low PRD at 1.34%. But for the record mit203 the maximum compression can be reach only 34:1 with the PRD of 5.22%, although this does not correlate to the lowest PRD value of the other arrhythmia types. However, the performance of the proposed algorithm is provides higher CR and smaller PRD for only the regular format ECG signal (Eg: 117, 102, 103 …), except for the case of QRS complex (203).

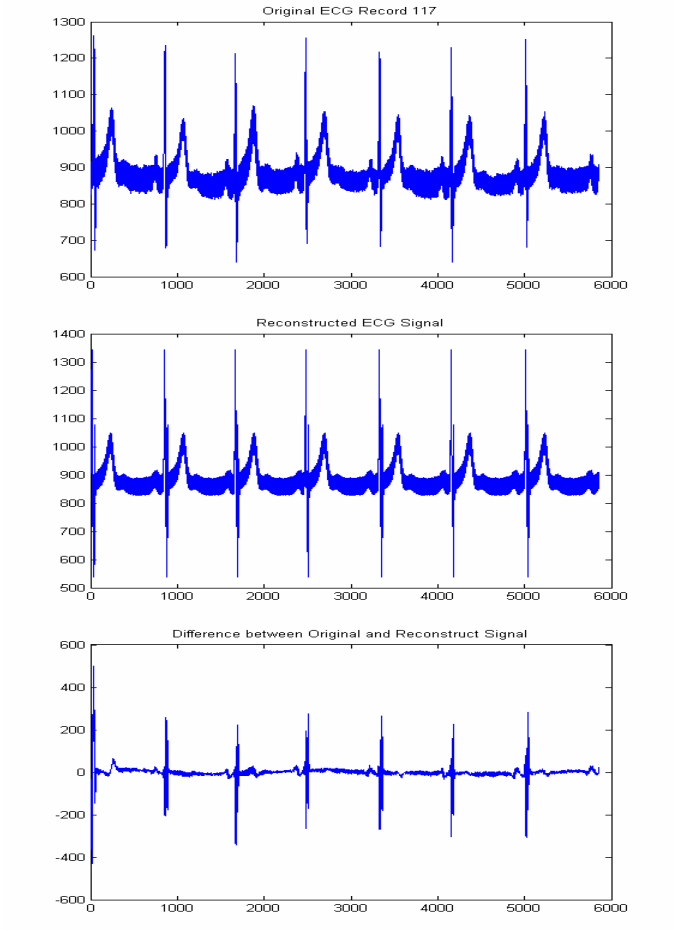

Fig.5 The result of proposed method on mit117 (a) Original signal, (b) Reconstructed signal, (c) Reconstruction error.

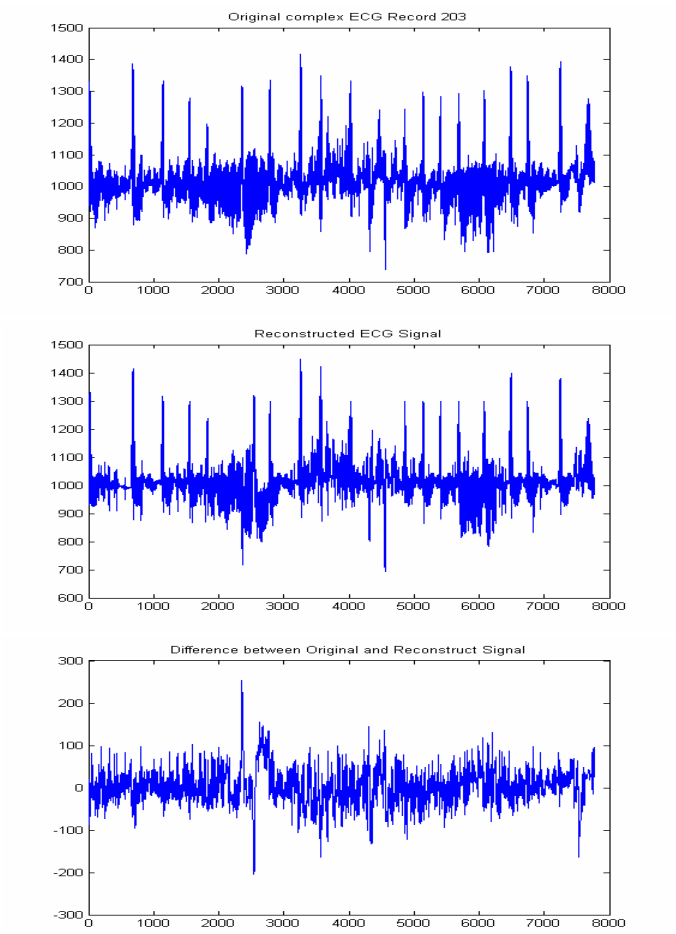

Fig.6 The result of proposed method on mit203 (a) Original signal, (b) Reconstructed signal, (c) Reconstruction error.

IV. CONCLUSIONS

The hybrid method of ECG compression by Wavelet based Average Beat subtraction has been proposed. This method consists of the QRS detection, period normalization, threshold technique of reduces the number of residual wavelet coefficients, and Run-Length Coding. The experiment results show that the average beat subtraction should produce relatively constant improvement in compression regardless of distortion level. However, our experiment indicate that a decrease of compression but increase the distortion level. It is because of the compression ratio (CR) depend upon the selected the Threshold index, and PRD is depend upon the number of beat selected to generate the mean beat at the average beat process and condition of the original ECG format.

***Abstract*-We develop a multi-channel electromyogram acquisition system using PSOC microcontroller to record multi-channel EMG signals. An array of 4 x 4 surface electrodes is used to record the EMG signal. B-spline interpolation technique has been utilized to map the EMG signal on the muscle surface. The topological mapping of the EMG is then analyzed to classify the pattern of muscle contraction. The purposed system was successfully demonstrated to record EMG data and its surface mapping. The muscular contraction classification of mapping using Principle component analysis demonstrates promising results.**

Keywords— PSOC, EMG, PCA

I. INTRODUCTION

Electromyography (EMG) is the study of muscle electrical signals. EMG is sometimes referred to as myoelectric activity. Many muscular abnormalities such as muscular dystrophy, inflammation of muscle, peripheral nerve damages could results in an abnormal electromyogram [1-4]. EMG can be recorded by two types of electrodes; invasive electrode the so-called wire or needle electrodes and non-invasive electrode the so-called surface electrode. Wire or needle electrodes records individual muscle fiber action potentials which is an ideal choice to evaluate the muscle activity [7]. However, fine wire intramuscular electrodes require a needle for insertion into the muscle and may cause a significant pain. The choice of surface electrode is then preferable. However, when EMG is acquired from surface electrodes mounted directly on the skin, the signal is a composite of all the muscle fiber action potentials occurring in the muscles underlying the skin. Estimating this force in general is a hard problem due to difficulties in activating a single muscle in isolation, isolating the signal generated by a muscle from that of its neighbors, and other associated problems [5-6]. The clinical application of EMG can be classified into two mains categories. (i) Standard EMG [6] is recorded from discrete sites on a muscle and thus provides only a limited picture of the actual muscular electrical activity in the vicinity of the recording electrode. EMG,(ii) EMG, recorded by an array electrode array facilitates the clinical interpretation of electrical activities through the mapping of these signals on the muscle surface [7]. In this paper, a PSOC-based multi-channel surface electrode array data acquisition system is developed to acquire EMG data. The EMG signals are then mapped using B-spline interpolation technique. The EMG topological Mapping is then used for classification of muscular contraction. There exists a number of 2D-pattern classification [7-10], in this research, we applied the technique called principal component analysis which is very efficient and widely used for classification. [11]

The paper is organized as follows: Section II is devoted to the specification and design concept multi-channel electromyogram system. Section III described feature extraction and topological mapping process. Section IV briefly introduced Principle component analysis. The classification results is shown in section V. Conclusions and Discussion is provided in section VI.

II. DESIGN AND CONSTRUCTION OF MULTI-CHANNEL EMG

EMG measurement is accomplished by the instrument called electromyography. The system, in general, consists of instrument amplifier, notch filter, offset adjustment, isolator, main amplification, and the CRT display. The instrument amplifier is a front-end, high CMRR differential amplifier which functions to pick-up a low amplitude signal submersed in the high-frequency noise. The notch filter gets rid of the 50Hz noise while keeping the EMG signal intact. The offset adjustment maintains the baseline level especially during the subject's motion. The function of isolator is to separate the front-end section from the rear-end section to protect the possible electrical shock to the patient. The main amplification conditions the EMG prior to be display with CRT. The complexity of the electronic circuit becomes realized with the necessity to monitor the multi-channel of EMG. Such complicate designs, however, are made possible by the creation of entirely reconfiguration and programmable components the so-called Programmable System On Chip Microcontroller(PSOC Microcontroller).

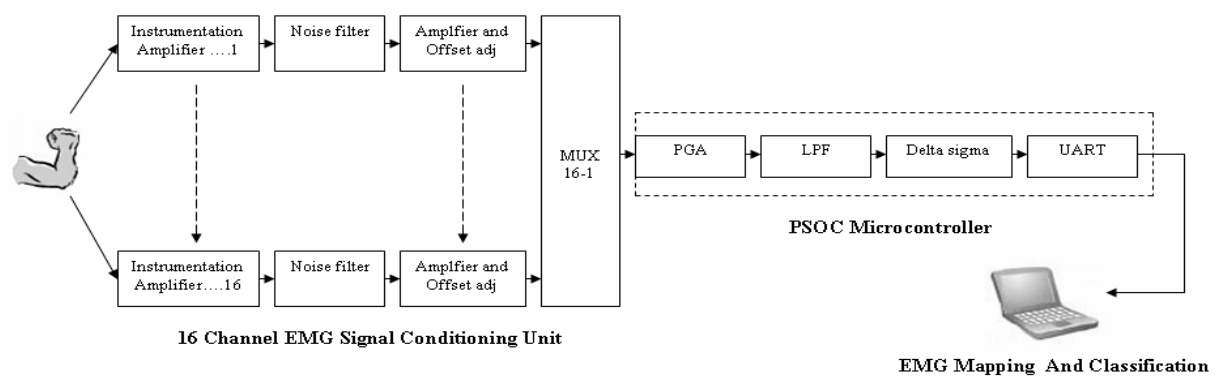

Figure 1. 16 channel electromyogram acquisition system

The designed EMG system is capable of monitoring 16 channels of EMG simultaneously. Each channel consists of 2 main parts; (i) EMG signal conditioning unit and PSOC microcontroller. Figure 1 shows diagram of multi-channel EMG acquisition system.

The EMG signal conditioning units consists of 3 sub-units

(i) Instrumentation Amplifier. This subunit uses the INA 2128 BUR-BROWN Integrated Circuit. The IC can achieve a CMRR up to 120 dB and gain up to 1000.

(ii) Noise filter. The function of the filter is to get rid of the 10-20 Hz noise which is classified as a motion artifact.

(iii) Amplifier and Offset Adjustment. The objective of this sub-unit is to Amplifier EMG signal and maintains the appropriate offset voltage prior to interface with the PSOC.

The PSOC microcontroller consists of 4 subunits

(i) PGA (Programmable Gain Amplification) This subunit acts as the buffer and the main amplification of EMG.

(ii) Low pass filter. The function of the filter is to remove of the high frequency noise. The cut-off frequency is at 500 Hz.

(iii) DELTA-SIGMA. This subunit functions as a 8-bit Analog to digital converter.

(iv) UART. This subunit functions to perform RS-232 interfacing unit with PC.

The captured EMG signal by the PC is displayed on the PC monitor. The display unit is written in C++ Builder. The function of PC is to display the Raw EMG signal (figure 3).

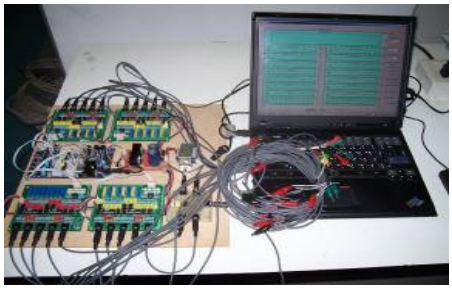

Figure 2. Multi-channel electromyogram acquisition system

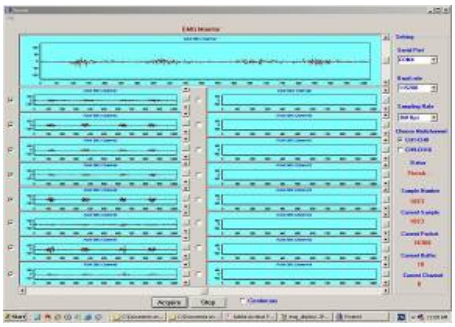

Figure 3. Raw EMG signal on laptop computer

III. EMG FEATURE EXTRACTION AND MAPPING

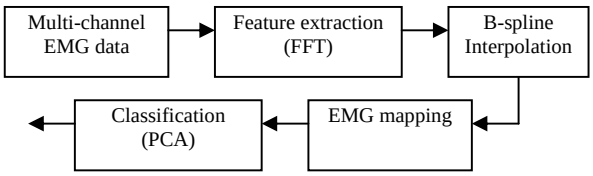

Figure 4. Feature extraction and mapping

Figure 4 show the feature extraction and mapping process. Each of the 16 EMG channels will be converted to frequency domain by taking the Fourier transform. The energy content of the EMG signal is then evaluated by computing area under the magnitude squared of the Fourier transform. The energy content on the 4x4 grid corresponding to the 4x4 electrode shown in figure 5 is then interpolated to derive the 49x49 topological maps which are later applied to PCA for muscular contraction classification. Figure 6 shows the topographical mapping of various muscular contractions.

Figure 5. 16 Channel electrode placements

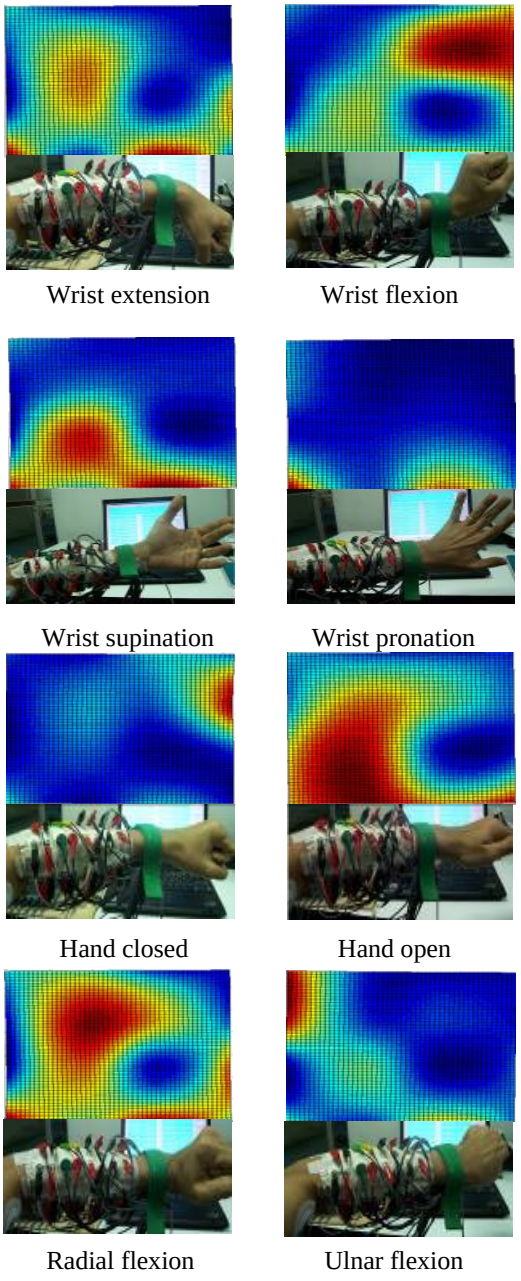

Figure 6. Topographical mapping of the EMG

IV. CLASSIFICATION USING PRINCIPAL COMPONENT ANALYSIS (PCA)

Principal Component Analysis (PCA) is a statistical technique which used to describe a large dimensional space with a relative small set of vectors. It is a popular technique for finding patterns in data of high dimension, and is used commonly in both face recognition and image compression. Application of PCA to face recognition is known as Eigen face. The Eigen face technique is a powerful yet simple solution to the face recognition dilemma. It uses much more information by classifying faces based on general facial patterns. Here we focus on the application of PCA for muscular-contraction classification

The procedure for using PCA is divided into 2 steps. (i) Training step and (ii) Classification step.

The Training step is as follow:

(i) Convert each cropped topological mapping matrix into a vector T_i of length N (N=imagewidth*imageheight). For the M data set, we let the training set represented by, $\{T_1, T_2, T_3, ..., T_M\}$ where M is the vector of N^2

(ii) Compute the mean vector Ψ and the set of deviation from the mean vector $\Phi = [\Phi_i, \Phi_2, ...\Phi_M]$ which is defined as

$$\Psi = \frac{1}{M}\sum_{i=1}^{M} T_i \quad (1)$$

$$\Phi_i = T_i - \Psi \quad (2)$$

(iii) Compute the covariance matrix C which is defined as

$$C = \frac{1}{M}\Phi\Phi^T \quad (3)$$

(iv) Compute the Eigen value and Eigen vector of C represented as

$$C\nu_i = \mu_i\nu_i \quad (4)$$

where μ_i is the corresponding Eigen value of Eigen vector ν_i

(v) Project each training set on the Eigen -space using the operation

$$\omega_K = (C\nu_k)^T(T_i - \psi) \quad (5)$$

$$1 \le k \le M', \quad 1 \le i \le M$$

where ν_k is ranked according to their significance. Therefore, for each topological mapping matrix we would have a set of M' weight

$$\Omega_k = [\omega_i, \omega_2, ..., \omega_{M'}] \quad (6)$$

which describe the contribution of Eigen space to the topological mapping matrix.

The Classification step is as follow:

(i) Project vector form of the tested topological mapping matrix T_p to the Eigen space using equation (4) to derive Ω_p. The tested topological mapping matrix is classified to class k which minimized

$$\varepsilon_k^2 = \left\|\Omega_p - \Omega_k\right\|^2 \quad (7)$$

with $1 \le k \le M$

V. EXPERIMENTAL AND RESULTS

The 5 patterns of topographical mapping of six muscular contraction of forearm (30 maps) are used in the training process of PCA. The topographical mapping of the five unknown contraction is then used as the tested set. Figure 7 shows the training sets , the derived Eigen-space and the result of classification.

TABLE I
The results of classification

Muscular contraction	% Accuracy
1.Wrist extension	80 %
2.Wrist flexion	100 %
3.Wrist pronation	80 %
4.Hand closed	100 %
5.Radial flexion	100 %
6.Ulnar flexion	100 %

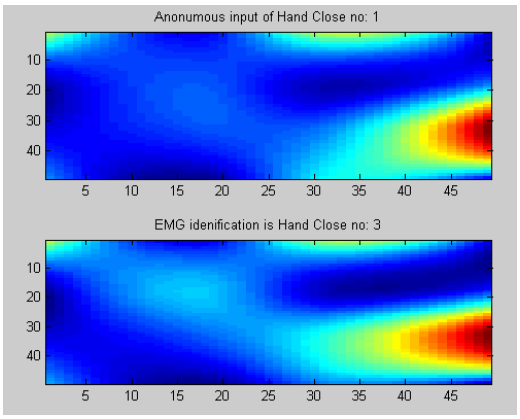
(b)



(c)

Figure 7 (a) Training Topological-Mapping Input of PCA; (b) Eigen space; (c) Result of classification

VI. CONCLUSION AND DISCUSSION

A multi-channel electromyogram acquisition system using PSOC is designed and constructed to perform a topological map of EMG signal on the muscle surface. The mapping for various pattern of muscular contraction are then recorded and later analyzed with principal component analysis (PCA) to classify the pattern of muscular contraction pattern. The classification result is very promising.

ACKNOWLEDGMENT

The authors wish to thank DEMAMEDICAL CO., LTD for supporting the ECG/EMG surface electrode and lead wire for measuring EMG signal in this research.

An Automatic Classification of Microcalcification Clusters Using Shape and Distribution Features

W. Chiracharit
Department of Electronic and Telecommunication Engineering
King Mongkut's University of Technology Thonburi
126 Pracha-uthit Road, Bangmod, Tung-kru, Bangkok 10140, Thailand

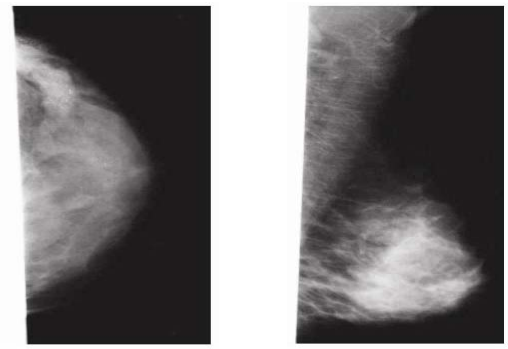
***Abstract*-This paper presents an automatic approach to classify benign or malignant microcalcification cluster which is an important sign of early-stage breast cancer, appearing on digitized x-ray mammograms. The approach consists of two main processes: detection of microcalcification cluster and classification of clustered-microcalcification features. In the first process, clustered microcalcifications are located in time-frequency wavelet space. Shape of the detected microcalcification is then morphologically reconstructed. In the second process, the features based on shape of a single microcalcification and distribution of the cluster are extracted. Binary tree decision, artificial neural network and support vector machine are used as a classifier to evaluate the performance. The experimental results show 86% sensitivity and 85% specificity.**

I. INTRODUCTION

Breast cancer is the mortal disease of most women worldwide. In Thailand, the statistical incidence of the disease is the runner-up [1]. Unfortunately, because its causes are not certainly known, screening of the disease in an early stage by x-ray mammography is currently the best option. Examples of mammograms are shown in Fig. 1. There are many abnormalities visible on mammograms, e.g. circumscribed masses or speculated lesions. An important sign of early-stage breast cancer usually appearing on mammogram is clusters of a tiny calcium deposit called microcalcification.

However, a restriction of low-contrast x-ray imaging and human fatigue causes a high risk of film interpretation error. This makes a large number of unnecessary biopsy or miss-detected existent cancer each year. Accordingly, a computer-aided diagnosis (CAD) using digital image processing and pattern recognition techniques can provide a second reading for assisting radiologists to increase their diagnostic accuracy and patients' survival rate [2]. CAD helps in detecting hidden small microcalcifications and making another diagnostic result.

In detection of microcalcification cluster, the x-ray passing through the breast tissue is scattered and makes incomplete image. Microcalcifications appear on low-contrast breast-tissue background image. The challenge is described as more difficult than finding a polar bear in a blizzard. In reading mammogram to find microcalcifications, the presence of microcalcifications in the image is not certainly known. Its presentation sometimes looks similar to the background or noise. There is much information about the microcalcifications for the radiologists, but the image shows just something that may be the microcalcifications.



(a) (b)

Figure 1 Examples of mammograms: (a) cranio-caudad view (b) medio-lateral oblique view

In the previous works on detection of microcalcification, Dengler *et al.* [3] proposed the segmentation by using the difference between original and low-pass images and morphology. Smith *et al.* [4] subtracted a smoothed image obtained by the morphology techniques from an original. The smoothing techniques are erosion, median filter, median filter with hollow mask, *k*-nearest neighbor filter and Gaussian filter. Morrison and Linett [5] directly detected the microcalcification by modeling microcalcification signal by a Gaussian function, and finding points that get the least error. Wang and Karayiannis [6] utilized wavelet decomposition to cut low frequency components that related to image's background, inverse wavelet transform and thresholding to select only high frequency signals.

In classification of microcalcifications, it is a difficult task to distinguish microcalcification types between malignancy and benignancy, because of its imprecise pattern depended on property of x-ray attenuation of each patient's breast tissues and image acquisition. In previous works, based on clinical knowledge, the types are judged by their size, shape, and distribution of clustered microcalcifications. Shen *et al.* [7] developed a set of shape factor to measure a roughness of a segmented individual calcification. Kramer and Aghdasi [8] used statistical texture features computed from both original suspicious region and its wavelet-transformed subbands. The whole information of the clusters and their background image was analyzed. Sehad *et al.* [9] added a clinical parameter of

patient's age on morphological features. Verma and Zakos [10] determined a significance of single and combination of the features randomly selected. All of these tried to extract suitable input features to feed to classifier such as Bayesian classification, k-nearest neighbors, or neural network. Another system structure was proposed by De Vito *et al.* [11]. The architectural approach is a multiple expert system that combined recognition results of each feature type and finally decided.

In this paper, an automatic classification of detected microcalcification clusters is presented. The paper proceeds as follows. The analysis of mammographic microcalcification is in the Section II. Section III is microcalcification detection and Section IV is microcalcification classification. The experimental results are in Section V. The conclusions and discussion are in Section VI.

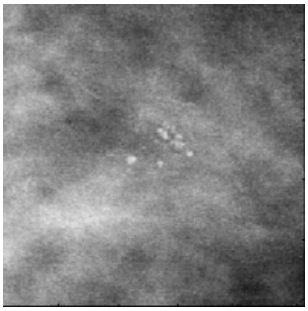


Figure 2 An example of microcalcification cluster

II. Mammographic Microcalcification Analysis

Microcalcification cluster looks like many bright small vary-shape spots [12]. Fig. 2 shows an example of mammographic microcalcification cluster. Normally, the mammogram consisting of the images of breast tissues, blood vessels, fat, microcalcifications, noises, chest muscle, air, other artifacts, etc. The intensity of breast tissue background increases or decreases slowly, while the intensity of small peak of microcalcification changes rapidly. They can be divided into three big groups: background, microcalcification and noise. The image signals of low-contrast background vary inconstantly, but totally are at high values. The image signals of microcalcifications are in minor group hidden in the image, and small noises are scattering throughout the entire image. In fact, the signals of the mammogram consist of many frequencies and intensities at any locations. Therefore, the microcalcification detection and classification without the flexibility of these changes may not succeed. The proposed approach is shown in Fig. 3. The details of each process are described in the next sections.

III. Microcalcification Detection

Firstly, the mammogram images are considered. Most image signals in the mammogram are an air, chest muscles or other artifacts that are not part of the breast. Therefore, to detect the microcalcifications without wasting time for processing these unrelated signals, the original mammogram image is divided into square regions of interest. Only the subblocks containing the breast images which may include the microcalcifications are considered. The other parts of the mammogram images are abandoned.

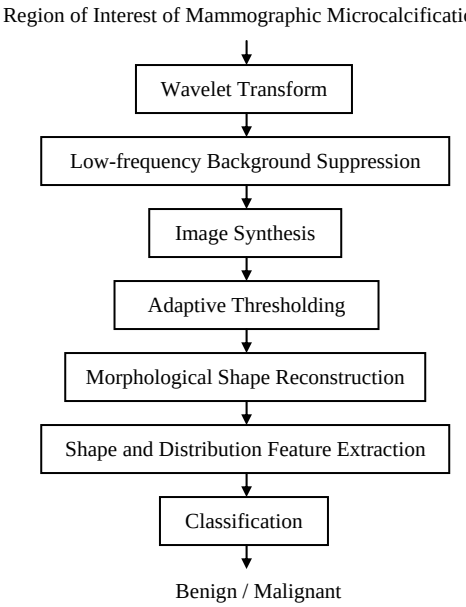

Figure 3 The automatic classification of microcalcification cluster

A. *Wavelet Transforms*

Since the microcalcification is related to high frequency component in frequency domain, and background behaves as low frequency signal. The spectrum of the signal or signal analysis in frequency domain is considered to be effective for the microcalcification detection.

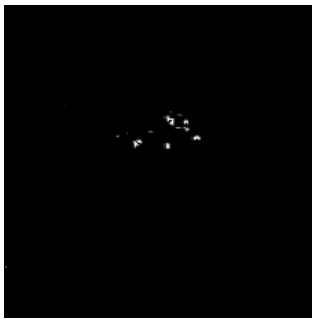
Wavelet transform [13], [14] is an analysis for decomposing or mapping the signals into coarse and fine components in time-frequency domain. It can represent all of the non-stationary image signals, which is appropriate for the mammographic analysis. However, in typical wavelet transform, only low frequency component will be decomposed into higher levels up to a size of the image (e.g. eight levels available for 256×256 pixel-size). The high frequency components of microcalcification signals are not performed.

B. *Background Suppression*

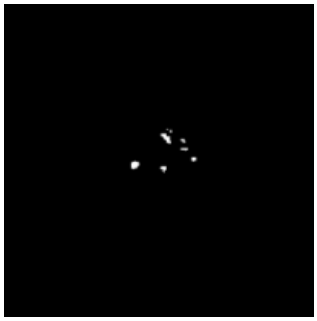
The level of wavelet decomposition and the type of mother wavelet are the conditions of the transformation that must be found. Higher levels mean that finer approximation are analyzed with longer processing time, while the types of the mother wavelet refer to the quality of the output signals. This means that the low frequency component are considered to be background.

The digitization of mammograms is performed with 300 dot-per-inch resolution and 8-bit gray scale. Therefore it is possible

that the smallest point of microcalcification being about 85 microns can be detected. The average size of a single microcalcification is around 300 microns. Because of wavelet a half-down-sampling for every decomposition level, therefore there are three possible levels in order to detect the smallest microcalcification. Daubechies 4 mother wavelet with the similar shape as microcalcification is selected. The coefficient of low frequency component in the selected highest level is replaced by zero, in which case the highest level is two. Then, the signal without the low-frequency component after the inverse wavelet packet transform has no background signals.



(a)



(b)

Figure 4 Examples of detected microcalcifications:
(a) thresholded synthesized-microcalcifications
(b) shape-reconstructed microcalcificatrions

C. Microcalcification Synthesis and Shape Reconstruction

After eliminating the background, the high frequency components representing only the microcalcifications are considered to be detected. All subband images are inverse-wavelet transformed. However, some noises and parts of background still remain in the reconstructed signal after the inverse wavelet packet transform, even though their amplitudes are very tiny compared with those of the microcalcifications. At the moment, some processes such as binarization for separating microcalcifications from the others are needed. The appropriate thresholding value has to be determined by using the image's histogram from which the microcalcifications are high-intensity minor part and other signals are low-intensity major part. The weighted threshold is balanced and selected. Then, the unwanted parts are cut. For example, the location of clustered microcalcifications in Fig. 2 is clearly detected, as shown in Fig. 4 (a).

The binarized microcalcifications may be detected with incomplete shape. The morphological closing is performed. The same location of microcalcifications in the original image is used to limit the boundary of morphological shape. The results are shown in Fig. 4 (b).

IV. MICROCALCIFICATION CLASSIFICATION

Classification of microcalcification clusters with features corresponding to a complex phenomenon of benign and malignant types is a hard problem. It requires suitable extracted features that can explain their exact clinical characteristic. The malignant type is typically different from the benign in shape, contour, size, number, or distribution in the cluster. Twelve features are chosen based on the characteristics of clustered microcalcifications in Table I [15].

TABLE I
CHARACTERISTICS OF MICROCALCIFICATIONS [14]

	Benign Type	Malignant Type
Shape	homogeneous rounded	dot-like or elongated form
Outline	Sharply	fragment with irregular
Size	generally larger	tiny
Number	solitary or numerous	very numerous
Distribution	Diffusely	clustered
Density	very fine and dense	differ granular

D. Shape and Distribution Feature Extraction

There are eight shape features. They are mean and standard deviation of Fourier descriptor, compactness chosen to describe the shape of the microcalcifications, mean and standard deviation of size of a single microcalcification, and mean and standard deviation of densities of microcalcification intensity.

There are four features representing the distribution of microcalcification cluster. Arrangement features are the distribution in the cluster that is represented by the area of the cluster, density, and mean and standard deviation of the distances between the micocalcification pairs.

E. Classifiers

Three classifiers are selected for two-class classification. The results are compared to find the best decision on the extracted features. The first classification is a simple binary tree decision. Each feature is decided into two classes. The decision tree is constructed for all possible paths and branches.

An artificial neural network learning with the back-propagation algorithm [16] is the second classifier for the more complex feature set. The feed-forward network is constructed with three layers.

The last classifier is support vector machine (SVM) [17], [18] which is a learning algorithm that is to find the largest separation margin between two classes. This is suitable for the high-variance feature set. Typically, only a few training samples will be the support vectors. In the experiments, there are three kernel functions based on the transformation or the

mapping of the input features into higher-dimensional feature space: linear kernel, polynomial kernel, and Gaussian radial basis function (RBF) kernel. The maximum soft margin is optimized from the dual form of SVM.

V. Experimental Results

Thirty mammogram films are from ten woman patients aged 35-62 years old. All mammograms are ground-truth known. The mammograms include both medio-lateral oblique (MLO) views and cranio-caudad (CC) views for both left and right breast images. Thirty-six regions of interest is cropped by the size of 256×256 pixels. There are 18 benign microcalcification clusters and 18 malignant microcalcification clusters.

TABLE II
Classification Results

	TPF	TNF	Classification Rate	A_z
Binary Tree	82%	76%	79%	0.74
Neural Network	84%	84%	84%	0.83
Linear SVM	84%	82%	83%	0.85
Polynomial SVM	86%	85%	86%	0.87
Gaussian-RBF SVM	85%	84%	85%	0.86

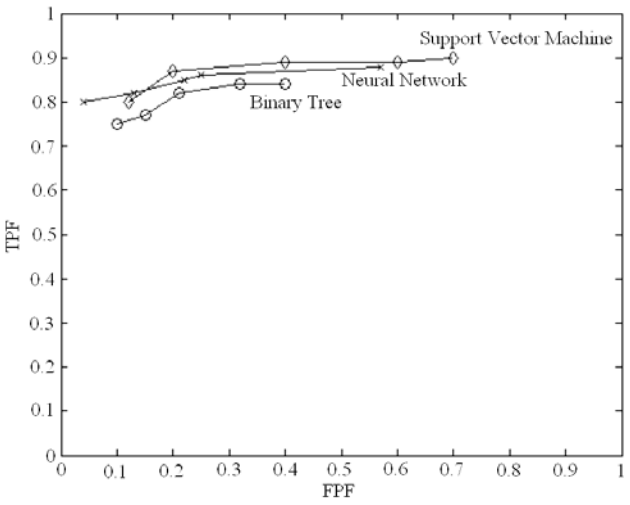


Figure 5 Comparison of ROC curves

The results of malignant or cancer case are true-positive and false-positive, and for benign or non-cancer case are true-negative and false-negative. They are used to compute sensitivity or true-positive fraction (TPF), and specificity or true-negative fraction or one minus false-positive fraction (1-FPF) [19]. The receive operating characteristic (ROC) curves are plotted to compare the results tested with different classifiers.

The experimental results are shown in Table II. The highest results is 86% sensitivity and 85% specificity by using polynomial support vector machine, shown in Fig. 5. The classification rate for all benign and malignant clusters is 86% area under ROC curve (A_z) is approximately 0.87. Although the results for any classifiers are not different, except binary tree, the results show significant results in both sensitivity and specificity.

VI. Conclusions and Discussions

This paper presents an automatic approach for classification of benign or malignant microcalcification cluster which is an important sign of early stage breast cancer appearing in mammogram. Clustered microcalcifications are detected and shape-reconstructed. Shape and distribution features are then extracted and classified. In the future, the CAD for full-field mammogram should be considered for the automatic diagnosis. All parts of mammogram should be analyzed.

***Abstract*- A 3D shape-recovery system based on photographic tomography is purposed in this paper. The system consists of a 12 digital camera mounted on the acrylic cases in flexible orientation. The photographs taken by these camera are served as projection data in the conebeam tomography. The 3D shape-recovery process can be divided into 2 steps; (i) calibration step and (ii) tomographic step. In the first step, all cameras capture a reference box performing the camera orientation to derive extrinsic camera calibration matrix. In the second step, the output volumetric data of the conebeam tomography is re-oriented using the extrinsic calibration matrix before undergoing a 3D backprojection step of tomography. The system is tested to recovery a varieties of object and the results are successfully.**

I. INTRODUCTION

3D shape recovering and modeling is the first step of the measurement chain in a number of applications including robot navigation, machine inspection, 3D object recognition, distance measurement, level control, profilometry, displacement measurement, and so on. Many techniques have been purposed for 3D shape recovering including stereo disparity [1-2], laser range finder [3-5], structured light [6-14], etc.

In this research, the concept of photographic tomography is applied for the 3d shape recovering system where the camera orientation can be varied arbitrarily and hence does not require the sophisticated circular scanning system for the camera around the object. The process is divided into 2 steps: (i) the camera calibration to determine the intrinsic and extrinsic parameters of the camera and (ii) modified tomographic process to reconstruct the pseudo cross-section of the object.

This work is organized as the following: - Section II discusses theory involved in tomography. Camera modelling is briefly introduced in section III. Shape extraction process are provided in section IV. Section V explained experiments and results. Discussions and conclusions are given in section VI.

Keywords: Image Reconstruction, 3D Rendering,Photographic Tomography, Cone-Beam Tomography

II. PHOTOGRAPHIC TOMOGRAPHY

The photographic tomography could be inferred as the one of a shape extraction system capable of reconstructing the volumetric data of an object from the sequence of photographs taken around the object.

The well-known algorithm for photographic cone-beam tomography is called Feldkamp cone-beam tomography [15]. The Feldkamp algorithm based on a 3D filtered backprojeciton. The generalized cone beam image reconstruction is expressed as follows:

$$f(x,y,z)=\frac{1}{2}\int_0^{2\pi}\frac{D_{SO}{}^2}{(D_{SO}-s)^2}R_\beta\left(\frac{D_{SO}t}{D_{SO}-s},\frac{D_{SO}z}{D_{SO}-s}\right)d\beta \qquad (1)$$

where $f(x, y, z)$ is the volumetric data, $R_\beta'(p, \zeta)$ is the two-dimensional silhouetted projection, β is the rotational angle, D_{SO} is the cone distance, and (t, s) are the coordinates which are rotated from (x, y). The 2D image taken from the camera normally is served as the projection data for Cone-beam photographic tomography

III. CAMERA MODELING

An photograph taken by a camera undergoes a linear transformation from the 3D projective space ρ^3 to the 2D projective space ρ^2 which can be described by the equation:

$$\begin{bmatrix}u\\v\\w\end{bmatrix}=K[I_3\,|\,O_3]\begin{bmatrix}R & -T\\ O_3^T & 1\end{bmatrix}\begin{bmatrix}x\\y\\z\\1\end{bmatrix} \qquad (2)$$

A scene point $[x\ y\ z\ 1]^T$ is expressed in a world Euclidean co-ordinate system and $[u\ v\ w]^T$ is the image of a scene point in pixel unit.

Matrix K in equation is eq (3) the intrinsic camera calibration matrix

$$K = \begin{bmatrix} fa & 0 & u_0 & 0 \\ 0 & fb & v_0 & 0 \\ 0 & 0 & 1 & 0 \end{bmatrix} \quad (3)$$

where f is the focal length of the projection, a and b is the conversion factor from physical unit to pixel unit and (u_0, v_0) is the principal point of the projection.

Matrix R and T contributes to the extrinsic camera calibration matrix. Rotation matrix R expresses three elementary rotation of camera Euclidean co-ordinate axes with respect to the world Euclidean Coordinate system- rotation along x, y and z are termed pan, tilt and roll respectively. Translation vector t gives three elements of the translation of the origin of the world co-ordinate system with respect to camera co-ordinate system.

To obtain M, observe each known point X=$[x\ y\ z\ 1]^T$ and its corresponding 2D image point $[u\ v\ w]^T$ yield an equation

$$\begin{bmatrix} x & y & z & 1 & 0 & 0 & 0 & 0 & -ux & -uy & -uz & -u \\ 0 & 0 & 0 & 0 & x & y & z & 1 & -vx & -vy & -vz & -v \\ & & & & & \vdots & & & & & & \end{bmatrix} \begin{bmatrix} m_{11} \\ m_{12} \\ \vdots \\ m_{34} \end{bmatrix} = 0 \quad (4)$$

or **AM=0**

If n such points are available, A will be of size 2n x 12. To solve for M, perform Singular Value Decomposition (SVD) of A to derive A=UDV^T. The last column of v is the solution for M. To separate extrinsic parameter, observe that M can be written as $M = [A|b]$ then $T = -A^{-1}b$. To determine R, we decompose A into a product of two matrices K and R using QR decomposition

IV. SHAPE EXTRACTION PROCESS

The entire process for the shape extraction from a series of photographs is shown as a diagram in Figure 1. This process starts with capturing a number of images of standard object (where the 3D coordinate with respect to the world coordinate is known) with camera in arbitrary orientation. The standard object is a cube with three axes of world coordinate passing through the lower corner of the cube. The 3D coordinates with respect to the world coordinate and their correspond image coordinates with reference to image coordinate system (which passes through the center of image) are used to compute the projection matrix M (Intrinsic and extrinsic camera calibration matrix) for each camera orientation as described in the previous section. The standard object is then replaced with object to be modelled. The series of image of the object are then captured with the same series of camera. The captured images are then turned into binary format where the background is equal to zero and the foreground is equal to one. As a result, this kind of shape extraction algorithm can extract the shape of any object regardless of the type of surface either the Lambertian or non-Lambertian surface. The binary images or the silhouetted projections are passed into the modified reconstruction algorithm in which the 3D reconstructed volume for each projection is reoriented such that the z-axis of world coordinate system is aligned with the camera co-ordinate system using the extracted rotation and translation matrix before implementing the general cone-beam tomography.

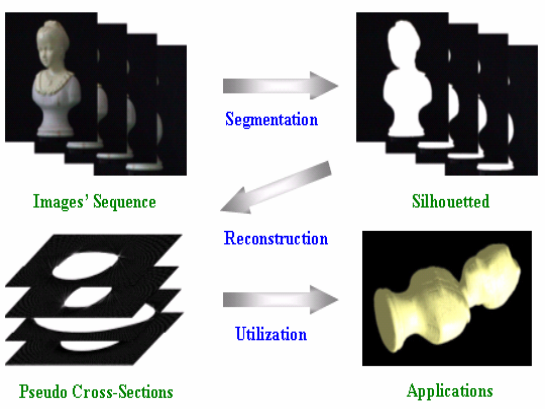

Figure 1. The process diagram of the photographic tomography

V. EXPERIMENT AND RESULTS

The 3D shaped recovery system shown in Figure 2 (a) is mainly composed of 12 USB cameras, and acrylic case. The cameras are installed on the case wall to capture photograph of object placed on the case floor. The taken photographs are forwarded to the Pentium 4 personnel computer via USB hub. Figure 2 (b) shows a reference box used in the camera calibration process. All cameras are requited to capture a reference box performing the camera orientation to derive extrinsic camera calibration matrix. Figure 3 (a) shows the photographs of object taken from 12 cameras. The shape-recovery results are shown in figure 3 (b) after performing surface rendering.

VI. CONCLUSION AND DISCUSSION

The 3D shape extraction using photographic tomography is studied extensively. The main idea of the method is that the tomographic imaging is used to reconstruct the stack of pseudo cross-sectional images from a series of photographs taken around the object. The shape of the stack can closely resemble the shape of original object. Compared with other 3D shape extraction techniques, the equipment used to collect the data for this technique is much lesser in complexity. It mainly consists of 12 digital cameras installed and taken the photograph around the object.

The proposed technique is tested successfully to generate the shape of a variety of objects. The shape with complex geometry such as hand requires more cameras to improve the shape recovery results. The application of real-time modelling is on progress.

Production Planning and Scheduling Approach in a Supply Chain

R. Masuchun
Faculty of Engineering
King Mongkut's Institute of Technology Ladkrabang
Bangkok 10520, Thailand

***Abstract*- This paper presents a linear integer programming model to plan and schedule production in a supply chain. In general, capacity constraints and operating sequences are ignored when generating MRP leading to many problems such as infeasible production plan on the shop floor. The approach proposed simultaneously plans and schedules for production at the same time capacity constraints and operating sequences are in consideration. The objective function of the proposed model is for scheduling purpose that is to minimize the makespan and tardiness of an order. Planning such capacity constraints and operating sequences as well as Bill of Material (BOM) is taken into consideration through several constraints. Numerical results verify that this model can be used to generate feasible and optimal schedule.**

I. INTRODUCTION

Problems always take place on shop floor since MRP and shop floor schedule are not synchronized. MRP does not consider capacity constraints and operating sequences; hence, production cannot be succeeded as planned [1-4]. Some jobs on schedule cannot be completed since the capacity is not enough. On the contrary, jobs requiring short operating time but not on the schedule cannot be alternatively put into operation as well because materials required have not arrived. Neither problem can be solved by solely conventional MRP or classic shop floor scheduling techniques. Advanced planning and scheduling is the solution to take capacity constraints and operating sequences into account when planning. This paper proposes an approach to simultaneously plan and schedule for production at the same time capacity constraints and operating sequences are in consideration. To consider both planning and scheduling, the scheduling part is handled through the objective function of maximizing efficiency of shop floor. The planning part including capacity consideration, operating sequences, and BOM procured or produced are taken into account by several constraints.

II. LITERATURE REVIEW

Research on advanced planning and scheduling has emphasized on heuristic approaches [2-3], [5-7]. Other research on mathematical modeling approach can also be found [8-10]. In [8], the relationship among items was ignored; in [9], only 2-level BOM was considered; and in [10], only makespan was considered in the objective function.

III. PROBLEM DESCRIPTION

When customer places an order, a due-date is set. Each order can comprise of more than one type of product. Each product requires certain subassemblies to be assembled into one unit of product. Each subassembly can be further congregated from certain components. Each component can be furthermore divided into certain items and so on. Subassemblies, components, and items can be either procured from outside or produced in-house. Either way requires some times to acquire. Fig. 1 displays four-level BOM of product A. Final product A comprises of one unit of subassembly x and four units of subassembly y. Two units of component i and five units of component j are assembled into one unit of subassembly x while one unit of subassembly y requires three units of component m and one unit of component n. Furthermore, one unit of component m comprises of one unit of item p and 2 units of item q.

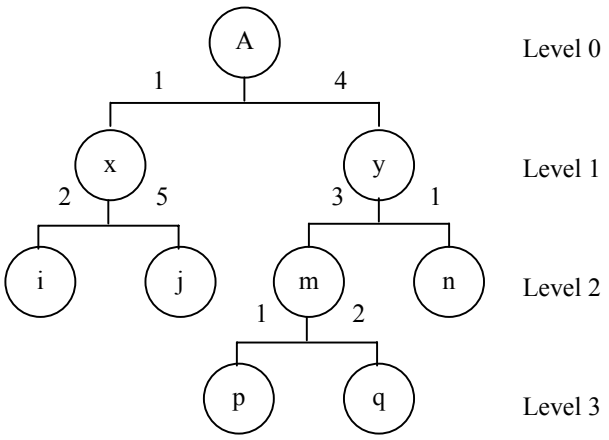

Figure 1. BOM of product A.

IV. MATHEMATICAL FORMULATION

Using the parameters and decision variables introduced in Table I, a linear integer programming model is constructed. The objective function is to maximize efficiency on the shop floor. In this paper, efficiency is defined in terms of both makespan and tardiness with constant multipliers of 5 and 2, respectively, as suggested in [11] so efficiency becomes a linear combination of makespan and tardiness. The objective function can be written as follows:

TABLE I
PARAMETERS AND DECISION VARIABLES

Parameters

O_{f,c,m_c} = Time required to obtain subassembly or component or item c belonging to final product f on the corresponding machine m_c

$n_{f,c}$ = Number of subassembly or component or item c required for one unit of final product f

$n_{f,f}$ = Number of final product f ordered

s_f = Arrival time of order consisting of final product f

DD_f = Due-date of final product f

M = A large positive constant

C(f) = Set of subassemblies or components or items required for final product or subassembly or component or item f

F = Set of final products

Decision Variables

t_{f,c,m_c} = Starting time of subassembly or component or item c belonging to final product f on the corresponding machine m_c

d_f = Completion time of order of final product f

y_i = 0 if $c_1 \in C(f_1)$ precedes $c_2 \in C(f_2)$ on the same machine $(m_{c_1} = m_{c_2})$; and 1 otherwise

ψ_f = 1 if $(d_f - DD_f) > 0$; and 0 otherwise

Objective function = Max (Efficiency)
= Min (Makespan and Tardiness)
= Min (5*Makespan + 2*Tardiness)

Makespan is the time taken to complete a set of final products and calculated as the time that the last final product in this group finished processing minus the time that the first item in this group starting processing. Tardiness is considered for each final product finished processing after its due-date and calculated as the difference between its finished time minus its due-date. A final product finishes processing before its due-date is not considered a tardy job and its tardiness is not included in the objective function. The objective function can be written as follow:

$$\text{Min } Z = \left[5 * \left\{ \underset{f}{\text{Max}}(d_f) - \underset{f}{\text{Min}}(S_f) \right\} + 2 * \left\{ \sum_f \psi_f (d_f - DD_f) \right\} \right].$$

Several constraints are needed to ensure an optimal and feasible schedule. The first and second constraints can be written as follow:

$$t_{f_1,c_1,m_{c_1}} + n_{f_1,f_1} * n_{f_1,c_1} * O_{f_1,c_1,m_{c_1}} \le t_{f_2,c_2,m_{c_2}} + y_i * M$$

or

$$t_{f_2,c_2,m_{c_2}} + n_{f_2,f_2} * n_{f_2,c_2} * O_{f_2,c_2,m_{c_2}} \le t_{f_1,c_1,m_{c_1}} + (1 - y_i) * M$$

$$\forall m_{c_1} = m_{c_2}, f_1 \in F, f_2 \in F,$$

$$c_1 \in C(f_1), c_2 \in C(f_2)$$

$$(f_1 = f_2) \rightarrow (c_1 \ne c_2)$$

Assuming that item c_1 belonging to final product f_1 and item c_2 belonging to final product f_2 demand processing on the same machine, only one of them can seize the machine and the other must wait until the machine is released. Ignoring the last terms in the first and second constraints, the first constraint ensures that item c_1 precedes item c_2 that is starting time of item c_1 plus the amount of total time required multiplied by total number needed must not exceed starting time of item c_2. On the contrary, the second constraint assures that item c_2 precedes item c_1 that is starting time of item c_2 plus the amount of total time required multiplied by total number needed must not exceed starting time of item c_1. For any given item c belonging to final product f, total number needed is calculated from number of item c required for one unit of final product f multiplied by number of final product f ordered. Since both constraints are conflicting and only one of them can be correct, they can be called either-or constraints. To be able to solve this model, a binary decision variable must be applied to each pair of either-or constraints. If this variable is 1, item c_2 precedes item c_1; otherwise item c_1 precedes item c_2.

The third constraint can be written as follow:

$$t_{f,c,m_c} + n_{f,f} * n_{f,c} * O_{f,c,m_c} \le t_{f,p,m_p}$$

$$\forall f, m_c, m_p, c \in C(p), p \in C(f)$$

For any given item c belonging to final product f and item p being the immediate parent of item c, the third constraint requires that item p cannot start processing until item c finishes its processing that is starting time of item c plus the amount of total time required multiplied by total number needed must not exceed starting time of item p. The last two constraints can be written as follow:

$$t_{f,f,m_f} + n_{f,f} * O_{f,f,m_f} \le d_f \qquad \forall f, m_f$$

$$t_{f,c,m_c} \geq s_f \qquad \forall f, m_c, c \in C(f)$$

The forth constraint defines the completion time of final product f. The fifth constraint makes sure that processing for any items assembled into final product f cannot be started until after order of final product f arrives.

The complete model can be rewritten as follow:

$$\text{Min } Z = \left[5 * \left\{ \underset{f}{\text{Max}}(d_f) - \underset{f}{\text{Min}}(S_f) \right\} + 2 * \left\{ \sum_f \psi_f (d_f - DD_f) \right\} \right]$$

subject to:

$$t_{f_1,c_1,m_{c_1}} + n_{f_1,f_1} * n_{f_1,c_1} * O_{f_1,c_1,m_{c_1}} \leq t_{f_2,c_2,m_{c_2}} + y_i * M$$

or

$$t_{f_2,c_2,m_{c_2}} + n_{f_2,f_2} * n_{f_2,c_2} * O_{f_2,c_2,m_{c_2}} \leq t_{f_1,c_1,m_{c_1}} + (1 - y_i) * M$$

$$\forall m_{c_1} = m_{c_2}, f_1 \in F, f_2 \in F,$$

$$c_1 \in C(f_1), c_2 \in C(f_2)$$

$$(f_1 = f_2) \rightarrow (c_1 \neq c_2)$$

$$t_{f,c,m_c} + n_{f,f} * n_{f,c} * O_{f,c,m_c} \leq t_{f,p,m_p}$$

$$\forall f, m_c, m_p, c \in C(p), p \in C(f)$$

$$t_{f,f,m_f} + n_{f,f} * O_{f,f,m_f} \leq d_f \qquad \forall f, m_f$$

$$t_{f,c,m_c} \geq s_f \qquad \forall f, m_c, c \in C(f)$$

$$t_{f,c,m_c} \geq 0 \qquad \forall f, m_c, c \in C(f)$$

$$y_i \in \{0,1\} \qquad \forall i.$$

V. Numerical Illustration

For an illustrative example, we consider two final products called product A and product B. Four-level BOM of product A and three-level of BOM of product B are shown in Figure 2. Each item requests a certain machine and requires certain amount of time for processing as shown in Table II. Values assigned to all other parameters required for solving this problem are shown in Table III. From table III, order 1 arrives at time 0 consisting of 150 units of product A with the due-date of 12000. At time 2, order 2 arrives demanding 100 units of product B with due-date of 11000.

The illustrative example was solved using the commercial software on a personnel computer. Starting time of each item is shown in Table IV and schedule on each machine is represented using Gantt chart as shown in Fig. 3.

TABLE II
Machine Requested and Time Required

Final Product	Item	Machine	Processing Time
A	r	M1	5
	s	M2	3
	p	M3	6

VI. CONCLUSION

In general, capacity constraints and operating sequences are ignored when generating MRP leading to many problems such as infeasible production plan on the shop floor. MRP and shop floor schedule should be synchronized. Planning and scheduling should be considered simultaneously. Solely conventional MRP or classic shop floor scheduling techniques cannot solve the problems. This paper presents a linear integer programming model to simultaneously plan and schedule for production at the same time capacity constraints and operating sequences are in consideration. The scheduling part is handled through the objective function of the proposed model that is to maximize efficiency of shop floor. The efficiency is defined in terms of makespan and tardiness. The planning part including capacity consideration, operating sequences, and BOM procured or produced are taken into account by several constraints. Numerical results verify that this model can be used to generate feasible and optimal schedule.

***Abstract*- Travel time estimation is an important component of Intelligent Transportation System (ITS). Many techniques for estimating travel time on various routes based on different types of sensors were proposed. In the past, stationary sensors were more popular, but they came with inflexibility, extra investment, and disruption to traffic flow during installation and maintenance. Global Positioning System (GPS) devices can also be used as mobile sensors but the signal penetration can be limited in the city environment. In this paper, we propose architecture of a context aware system for travel time estimation based on cellular probes in city environment. A cellular probe technique is our preference since necessary infrastructure is already in place without the weaknesses of stationary sensor techniques and GPS devices. The context analysis module in our system helps eliminate unrelated cellular probes from input data. Traffic data delivery methods are also discussed. Our system is very helpful for routes selection especially in the metropolitan area. The architecture of our system is open, flexible, extensible, and it can develop an evolutionary.**

I. INTRODUCTION

Travel time information is necessary for the journey planning and routes selection especially in the metropolitan area where people are interested in knowing time from an origin to the destination to plan a trip ahead. Travel time estimation is one important function in ITS.

Different approaches deployed various types of sensors for travel time estimation. A sensor is the hardware with assisted software that detects vehicles and converts the information into traffic flow data. Sensors that act as traffic data collectors can be stationary sensors and mobile sensors. We can categorize stationary sensors into intrusive detectors (installed in-roadway) and non-intrusive detectors (installed above roadway or sideline).

Intrusive detectors, such as inductive loop detectors (ILDs), have been used for several years to send traffic data to the traffic operators. However, this technology requires disruption to traffic flow during installation and maintenance, high failure rates in certain conditions, and inflexibility. Using non-intrusive detectors still lead to requirement of extra equipments installation just like the intrusive detectors. This is a time consuming task and needs extra investment. Deploying mobile sensors seems to be more flexible especially the cellular phone since the necessary infrastructures already exist and there is no disruption to traffic flow during installation and maintenance. In addition, mobile users are distributed all over the city, the number of mobile users is increasing day by day, and the problem of signal penetration is less than GPS in city environment.

To deploy cellular probe in travel time estimation, specifying valid cellular probes as samples is a primary challenge. There can be a lot of cellular phones that are un-related to the road traffic (e.g. mobile phone of pedestrians, in offices, in shopping mall, etc.) included in our input data set. Based on our literature review, some researches use cellular probes as traffic data originator, but very few of them offer the method of selecting valid samples in city environment and the majority of them do not apply the concept of context awareness to their systems.

"The context is any information that can be used to characterize the situation of an entity."[15] Almost any information available at the time of interaction can be classified as context. Context can include information such as identity, location, speed, acceleration, time of the day, date, season, temperature, people that are nearby, activities (e.g. walking, running), and schedules [19]. A system is context aware if it can extract, interpret and use context and adapt its functionality to the current context.

The public awareness of the actual traffic situation is very useful. It can assist the travelers in their route selection. Thus we design the context aware system for travel time estimation based on cellular information which can report the actual travel time through one of information representation methods.

Unlike other stationary sensor techniques, cellular phones are not designed to be the traffic data probes. Thus, additional works must be done to eliminate unrelated data based on context awareness concept. With our context analysis module, classifying related and unrelated cellular probes for further actual travel time calculation is possible.

This paper is divided into 4 parts. Part II reviews the existing travel time estimation techniques. Part III describes the

architecture and explanation of our system while the conclusion and future research can be found in part IV.

II. Travel Time Estimation Techniques

A sensor is a device with assisted software that detects vehicles and converts the information into traffic flow data. A sensor is an important component for the travel time or traffic condition estimation applications [17]. Different approaches applied various types of sensors as categorized in table1 [1, 2, 3, 4, 5, 7, 8, 9, 13]. Many travel time estimation algorithms were proposed based on each type of sensors or even data fusion algorithms for data from more than one type of sensors [18]. Some approaches apply various well known mathematic models in their algorithms.

TABLE 1
Examples of Sensor Technologies Used in Travel Time Estimation

Stationary Sensors	*Mobile Sensors*	*Mix Sensors*
Inductive Loop, Camera/ Video Image Processing, Microwave Radar, Passive and Active Infrared Devices, Ultrasonic, Passive Acoustic, Weight-in-Motion Detector, Magnetic Detector, Pneumatic Road Tubes, Piezoelectric Detector	Cellular Phone, GPS , Mobile devices equipped with video camera	Loop Detector + GPS Loop Detector + AVL

Most of stationary sensor techniques require installation of fixed infrastructure and dedicated instruments. For instance, video cameras incorporated with image processing algorithms to provide traffic flow information have a limitation if the weather condition is low visibility.

Mobile sensor techniques for traffic data collection have been studied lately. A probe vehicle and remote sensing method were primarily studied. Technologies in probe vehicle approaches include GPS, cellular phones, Automatic Vehicle Identification (AVI) and Automatic Vehicle Location (AVL). A remote sensing technology relies on satellite images to extract the traffic information. For more information of sensors technologies for ITS, readers can find in [16] and [17].

Satellite images associated with image processing can also provide the traffic data, but the same problem as using video camera or camera applied which is limitation on low visibility. In addition, cost of using satellite is quite high.

Cellular Phones as Probes

As the geo-location technology was developed, vehicle probes with cellular phones become attractive for many research groups. Cellular phone location tracking has been brought up to discuss as one part of the travel time estimation based on cellular information by many projects. The tracking data can come from either mobile phone equipped with GPS receiver, using Time Advance (TA), or triangulation method [2, 6]. However, the triangulation cannot tell the location of the phone within just a few meters [10]. Accuracy of a cellular geo-location technique remains as the challenge. Furthermore, tracking mobile phone position can lead to a privacy violation. This problem can be avoided by ignoring the data immediately after it is used and mobile phone numbers encryption so that it is not possible to know which phone made which trip [11]. In this section some examples of travel time estimation projects that rely on cellular probes are described.

In 2001, Ygnace and Drane [1] described the methodology and preliminary results from their study. The situation and environment were set up based on assumption that the location of cellular phones on the road are known by any of positioning techniques without proposing any methods to obtain positions.. The result from simulation tells that 5% of the total vehicle population per link is sufficient to allow precise estimation of travel time. This project is called INRETS which is the pilot of project named STRIP [2].

For STRIP project, the experiment was done on a stretch of 120 km of very crowded motorway. The distance between the mobile phone and the base station was obtained from the Time Advance (TA) when engaging in the phone call. The positions of mobile phones can then be calculated. All positions calculated to be out of threshold number centered on the motorway axis were discarded. Then a neuronal processing evaluates whether the mobile phone is located on the motorway or not, if yes, on which lane. The database of all time stamped locations of all mobile phones traveling on the motorway is used for travel time calculation [2]. Using TA to calculate positions must base on active cellular phones [6]. However, the possibility to have mobile phones in idle mode is higher.

Schneider and Mrakotsky [3] proposed a travel time estimation method by obtaining the coordinate of the cell transition of a mobile phone from GPS. This method is quite simple, but it needs vehicles carrying GPS receivers and mobile phones with special software installed. This can be a burden**.** The GPS coordinates gained at the moment of cell transition are registered via mobile phone and stored in the database. With the difference of the time stamp at cell transitions and the distance on the road between two cell transitions, the average speed was calculated.

It is noticeable that very few of cellular probe approaches offer methods to select valid samples in metropolitan areas. In addition, the majority of them do not apply context awareness concept to the systems.

III. Context Aware System for Travel Time Estimation Based on Cellular Probes in Metropolitan

Travel time information is an integral part of Intelligent Transportation System (ITS) especially for the journey planning and route selection. Sensors are necessary for making this task successful. Many stationary sensors have been used as traffic data collectors, but they come with inflexibility and requirement of extra equipments installation. Some of them come with disruption to traffic flow and some of them come with time consuming for installation. Mobile sensor can alleviate these obstacles, but some of them create other limitations as stated in part II. GPS has limitation in signal penetration in the city while cellular probe has fewer problems.

Satellite images can not perform well when the weather condition is not good such as when it is foggy or raining.

Calculating travel time information based on cellular probes has become an interest. Most projects have done experiment without offering solutions for selecting relevant cellular probes to the traffic. Nevertheless, selecting valid samples (here are appropriate cellular probes) is very important in order to get an accurate result. Our system thus provides the solution to this problem. Fig.1 presents overall architecture of our project.

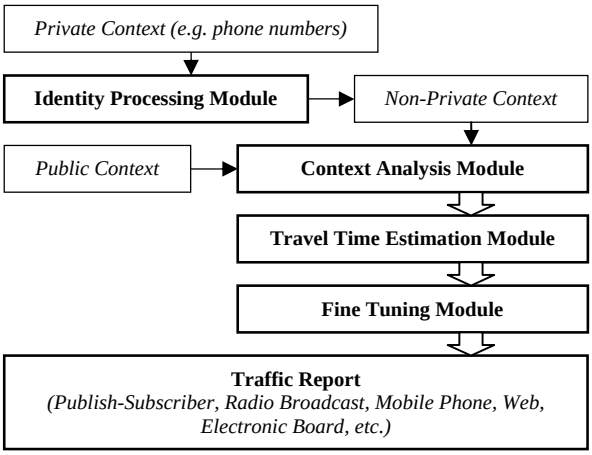

Figure 1. An architecture of a Distributed Context Aware System for Travel Time Estimation Based on Cellular Probes in Metropolitan Environment

The input of the system is context. Cellular phone locations, phone numbers, and base stations locations are examples of context attributes. Other context attributes are layout of the streets, building construction, events happening along the road, and type of cars as examples. For this project, some examples of context attributes are listed in Table 2. We aim to use minimum number of input context required, but provide the optimal, efficient, and accurate result.

To successfully deploy the system, the carrier's cooperation is important. The carrier who provides the cellular data can gain benefit from selling traffic data to mobile users. Anyhow, the carrier must strongly concern about each customer's privacy. Currently we cooperate with one of leading cellular phone operators in Thailand to provide us necessary data.

To track the cellular probes, the ID of each probe must be taken. The most convenient way is taking the phone number obtained from the mobile phone operator as the ID. However, the privacy consideration is important. This problem can be solved by converting a phone number into new unique number that can not tell what the original number is. Thus, to prevent our system from privacy violation, all "private context attributes" (e.g. phone numbers, names of mobile users, etc.) must get through the "identity processing module" which includes a one-way hashing function. Then they become non-private context attributes. For instance, an input phone number is hashed to another identity called "probe ID" that can represent each probe for a tracking purpose. With a one-way hashing function, after non-private context attributes are gotten and the input private context attributes are discarded, it is impossible to track back to get the original input. Locations of cellular phones in mobile networks can be obtained by using TA, triangulation, or detecting handover zone for instance [6].

TABLE 2
EXAMPLES OF CONTEXT ATTRIBUTES AND POSSIBLE USAGE

Context attributes	*Possible use of context attributes*
Location of mobile phones	- For cellular probe tracking - To help classifying related and un-related cellular probe to the traffic - For analyzing concentration and the location of groups of users
Phone number	- To generate the probe ID for tracking purpose - Can classify pre-paid and post-paid phone (for further analysis)
Location of base stations	- Can be used for map-matching - For analyzing and associate the mobile user within coverage area.
Layout of streets, buildings construction	- Can be used to compare with location of base station for our analysis. - Can be used to populate the geographic location and can provide navigation functionality.
Type of vehicles	- To help analyzing the density of cellular probe in particular location. (e.g. many passengers in buses, 1 driver in individual car)
Mobile users profile	- To help analyzing type of mobile users (e.g. bus driver, car driver, taxi driver) - To help personalizing the traffic report.
Time and Date	- To help analyzing the traffic congestion in particular location (e.g. high traffic in rush hour of the day, light traffic in the city during long weekend)
Weather condition	- To help analyzing the traffic congestion in particular location

Furthermore, the sample size of cellular probe is also one of important concerns. It was proved that 5% of the total vehicle population per link is sufficient to allow the precise estimation of travel time in the link. However, increasing number of sample size will result in more accuracy result [1].

Specifying valid cellular probes to be our samples while there are a lot of cellular phones that are un-related to the road traffic mixed in the input data set is a problem to be addressed. Thus, our system includes a context analysis module.

Context attributes are input of the "context analysis module" which consists of algorithm to analyze all context. Once context attributes go through the "context analysis module", we can tell either that cellular probe belongs to drivers of vehicles, pedestrians, or else. These can be told from situation of each probe extracted from input context attributes. Then we can choose valid samples to provide the accurate input for the next module, "travel time estimation module".

The travel time estimation module calculates the travel time based on travel time estimation algorithm. Travel time calculation can be as simple as taking the time-stamp difference of a tracked cellular probe between one reference location and another.

After obtaining the travel time information, the traffic report can be generated. There are many options to deliver traffic information to users. Traffic information can be broadcasted

through radio wave. Delivery through web application is another option such as in [3], but it might be inconvenient for drivers to access the web while they are already on the roads. Traffic information can also be presented on electronic boards mounted along the roads or at intersections, but data representation must be taking into account along with location selection to install electronic boards for the best perception. Colors maybe used to represent the traffic condition such as red, yellow, and green to specify the volume of traffic in each road. For example, [12] use color painted on a traffic map to represent traffic information based on pre-specified occupancy thresholds.

Moreover, the "publish/subscriber" technique may be chosen. Subscribed users may receive the traffic information through SMS on his/her mobile phone(s). This method is convenient for users, but well design of data representation is also needed. In addition, context awareness may be applied to help deliver appropriate information to each user based on his/her current location, his/her preference, his/her profile and user intent to support full pervasive computing environment.

Our travel time report will be very useful for journey planning or route selection which is quite important for drivers in the city. The obtained actual travel time information can also become useful parameter for other applications such as time of journey prediction.

IV. CONCLUSION

Travel time information is very important for the journey planning and route choice decision especially in the metropolitan area where people are interested in knowing the traffic condition along the route they are heading. This paper has proposed the architecture for estimating the actual travel time based on context and cellular probe. The cellular probes are chosen as our sensors because all necessary infrastructures are already in place thus there is no extra investment. Also there is no disruption to traffic flow during installation and maintenance. However, selecting valid samples (here are cellular probes) is a challenge. We apply concept of context awareness to the system to eliminate unrelated cellular probes from input data. Our system can develop an evolutionary. Building the prototype system is in progress and the prototype will be tested in Bangkok using cellular information provided from one of the major cellular phone service providers in Thailand. Employing our system to metropolitan area such as Bangkok, known as a city with serious traffic congestion problem, will help drivers make better decision to reach parts of the city. The actual travel time report can also help improving the traffic management and control. Thus the traffic congestion can be alleviated.

Our system can be extended to report other traffic information in addition to the travel time information. More modules can be added to make the system more functionality. Our system can also be expanded to include the traffic prediction based on any prediction algorithms in the future. Thus it is extensible, open and flexible.

ACKNOWLEDGMENT

Ontology Development: An Integrated Engineering Approach

Paola Di Maio
School of Information Technology
Mae Fah Luang University, Chiang Rai Thailand
Paola{at}mfu.ac.th

Abstract - Ontology engineering (OE) is becoming increasingly critical to systems development, and more and more observers, researchers and scholars from all disciplines are learning to appreciate its practical importance and underlying relevance to knowledge based systems development. Yet the current understanding of ontology, especially regarding development and application of standard, methods and practices, according to recent research, does not meet the growing challenges arising from the complexity of increasingly dynamic environments. This paper, on the basis of recent research findings , analyzes ontology development activities as scheduled in the most commonly adopted ontology engineering methodologies (OEM), and identifies weaknesses in the application of certain 'standard' activities - such as requirements engineering, user centered engineering and knowledge engineering - which have become central to modern engineering practices overall. It concludes by suggesting that such activities can address at least in part some of the weaknesses in current OEM, and could be critical to the effective ontology development, therefore it advocates the integration of additional perspectives in the development of future OE methodologies.

I. INTRODUCTION

As we move from data and information centric architectures to knowledge based systems and economies, understanding and implementing ontology is becoming increasingly important for all stakeholders. An ontology is what delimits and formalizes the 'knowledge universe' underlying any information system. Gruber's early definition of an ontology [1] as "a formal specification of a conceptualization" is widely accepted, although novel and more specific interpretations of the word 'ontology' are being developed by the day to fit the variety of scopes and applications that ontology serves in different communities. Despite its importance and growing popularity, Ontology is still a domain largely dominated by theorists and academics.
Some of the weaknesses in existing instruments, demonstrated in recent research [2], need to be resolved in order for OEM to support participation of wider individuals and communities in building, maintaining and adopting conceptual and semantic frameworks.

Background
This paper takes into account the established trend towards 'agile' development practices [19] according to which planning and design activities in any system development are better undertaken iteratively and with ongoing input from users. It also takes into account the shift towards web based 'collaboration' and SOA architectures, and the need for shared, flexible and participatory development processes. It identifies key areas for improvement of existing OEM by suggesting the adoption of an integrated approach that incorporates approaches and best practices from other directly related and established engineering methods.

Problem Statement
Recent research [3], as well as empirical evidence gathered from direct observations of related work groups, shows that existing ontology engineering methodologies are not adequately supporting the growing challenges of ontology development in complex, dynamic environments. While novel methodologies are being proposed [4] that specifically attempt to support collaborative knowledge acquisition [5], no methodology to date addresses the knowledge lifecycle requirements satisfactorily and reliably. Additionally, among the other activities that have not been explicitly and systematically address by existing OEM are Knowledge Abstraction, and the overall application of principles of User Centered design. We discuss briefly their relevance to OE in further sections.

Scope Of Paper
In analyzing key research findings in this area, including studies that carry out detailed evaluation of established OE methodologies [7], we identify activities that, irrespective from the chosen method, are underspecified in ontology lifecycle - namely requirements analysis (as opposed to requirements specification), knowledge abstraction, as an intermediate step between knowledge elicitation and representation, and generally limited application of user centered principles of design

II. FROM SOFTWARE TO KNOWLEDGE ENGINEERING

'Fit for purpose' software and knowledge based programs are the result of highly challenging and articulate development projects, where, given the complexities, the risk of failure to meet expected outcomes is very high [6]. In recent years, Software Engineering methodologies have specialized and become quite sophisticated and sometimes increasingly structured in order to systematically reduce such risks. Methodologies, (IEEE, 1990) are generally composed of processes, activities and tasks.
The focus of Ontology Engineering methodologies is the structuring and representation of domain knowledge underlying system development. They are still being experimented and researched, and they are not yet

'standardized'. Currently a shift is taking place from data centric systems towards 'open' knowledge based and semantic systems, thanks to fast advancements in web technologies. It is therefore becoming paramount that an explicit integration of methodologies also takes place, to support adequately the development of systems that are increasingly hybrid in nature, and that increasingly rely on knowledge, unstructured content, and a semantic layer.

III. ONTOLOGY ENGINEERING METHODOLOGIES

Ontology Engineering methodologies are adopted to support the development conceptual, semantic and reasoning models underlying robust and usable knowledge systems. However research demonstrates that such methodologies are not yet sufficiently developed to fully support the growing challenges of distributed cognitive processes in dynamic social and knowledge environments. In particular weaknesses have been identified in various areas including Knowledge Acquisition, as well as in areas relating to the Organizational and Technical processes of the methods. [2]

Typical activities in OE

OEM have evolved dramatically over the past ten years, since the first workshop on Ontological Engineering was held at the 12th European Conference on Artificial Intelligence in 1996. Known methodologies analyzed by literature [7], [8], are summarized in Table 1. Ontology Engineering activities vary in scope and focus [7] depending on the methodology, but they can broadly be grouped in the following categories :

- *Development* (feasibility, specification, conceptualization, formalization, implementation)
- *Support* (knowledge acquisition, evaluation, integration, merging, aligning, documentation, configuration
- *Management* (scheduling, control, quality assurance)

Such activities above are generally carried out simultaneously, or in different order depending different focus and perspective, of each methodology which privileges and proposes a different sequence and emphasis on certain activities and tasks, as it can be seen from the example in figures 2, 4, 5, 6.

The comparative study of the most commonly adopted OE methodologies concludes that given the wide diversity of ontology development strategies, each offer advantages and shortfalls, and none covers satisfactorily the entire spectrum of processes involved in ontology building. Indicatively, Methontology is identified as the method that provides the most accurate descriptions of each activity, and On-To-Knowledge methodology describes more activities than the other approaches. [7]

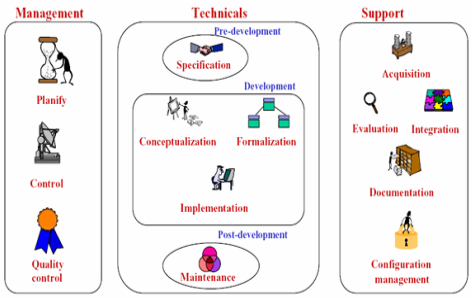

FIG 2 ACTIVITIES IN METHONTOLOGY METHOD

Cyc method
Uschold and King's
Gruninger and Fox's
KACTUS
METHONTOLOGY
SENSUS
ON-TO-KNOWLEDGE

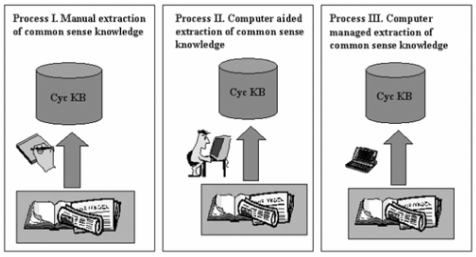

FIG 3 Processes in CYC Method

Among other shortcomings, OE methods overall, fail in varying degrees to adequately carry out essential activities such as requirements analysis, knowledge abstraction and fail to apply user centered design principles, and even when they do make a provision for such activities to be carried out, they are not necessarily undertaken at the right phase of the lifecycle, nor in sufficient detail. In Ontoknowledge for example [fig 4] and Methontology although there are explicit provision for 'requirements specification', there is not explicit provision for requirements analysis as a very distinct activities that should be carried out separately with distinct modalities (FIG 3) and end up with different deliverables, according to best practices [16], [17], [18]

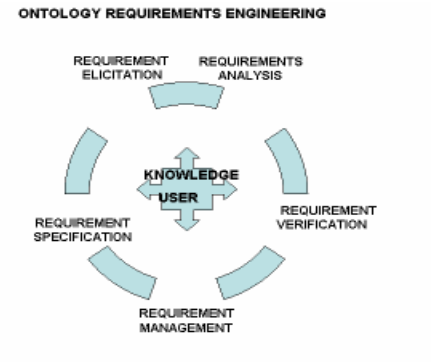

FIG 3

Similarly, 'knowledge conceptualization and representation' activities are bunched up in the same sub-process, while according to established knowledge engineering methodologies such as KADS, they are two very different activities that should be carried out separately in different phases of the knowledge lifecycle, resulting in different outputs [13]. The lack of in depth integration of different engineering perspective and approaches contributes to the weakness of the current OE methodologies, and contributes to limited accessibility and usability of knowledge and information currently being designed to be stored and exchanged on the web via commonly available browser based agents, thus inhibiting the full deployment of the vast application potential of the semantic web as intelligent agent.

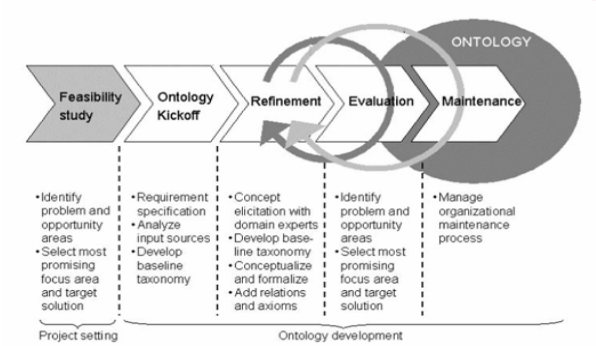

FIG 4 - Activities in Ontoknowledge Method

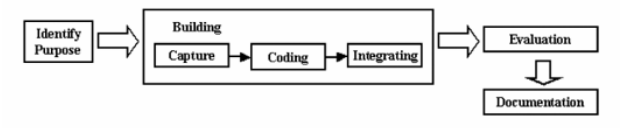

FIG 5 - Process in USHOLD KING Method

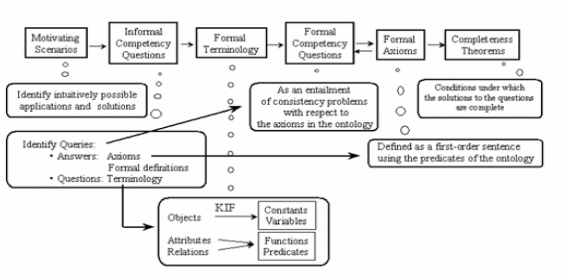

FIG 6 Processes in Gruninger and Fox Method

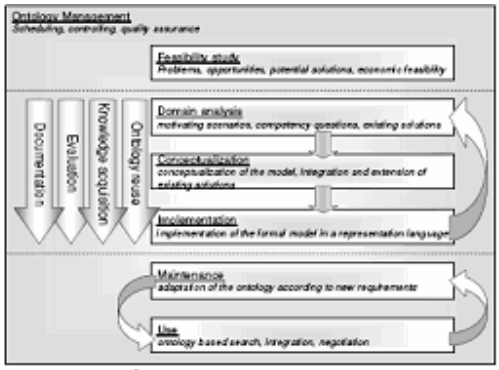

FIG 7 Ontology Engineering Activities
Source http://ontocom.ag-nbi.de/docs/odbase2006.pdf

Our comparative analysis of the processes, activities and techniques of recent studies [14], as well a empirical research and discussion in related workgroups, leads to the additional conclusion that:

1. Those methodologies which carry out requirement specification activities, do not have a sufficiently detailed, documented and structured 'requirements analysis' activity separately from the 'requirements specification' phase.
2. None of the methodology has a formal, iterative 'open consultation process' whereby all the stakeholders are requested to give feedback, and feedback is not scheduled as routine activity

None of the methodologies includes an intermediate process between knowledge acquisition (KA) activities and knowledge representation (KR), such as Knowledge Abstraction (Kab)

IV. RELATED ENGINEERING METHODS

After extensive review of related literature and studies, as well as direct observation and participation in related communities of practices [9], we conclude that at least three additional perspectives and approaches should be included in novel OE methodologies currently being developed:

Requirements Engineering (RE)
Requirements Engineering [10] is a key practice, although often underestimated and summarily carried out, especially

in ontology design. There are different kinds of requirements: operational, user, functional and non functional and each deserves to be developed systematically and independently from each other, and to be modeled into an Ontology Specification. RE consists of a set of detailed activities that should be undertaken in more structured form by OEM, namely requirements development (elicitation, analysis, specification, and verification/validation), and requirements management (fig 3). Getting the requirements wrong is likely to deliver unexpected limitations of the end result.

Knowledge Engineering (KE)

Knowledge engineering main contribution to modern development practices are methodologies that contain activities and techniques for the elicitation, analysis and structuring of knowledge. Although many such activities are common to other engineering practices, such as SE, KE is based on unique activities which are proper only to the 'Knowledge lifecycle', namely, knowledge acquisition, knowledge modeling, abstraction and representation. KADS [13], the best known structured methodology for knowledge engineering, formally includes systematic activities for knowledge analysis and design at different levels of abstraction. In recent discussions among peers in the ontology and related W3 workgroups [9], the lack of a properly defined and standardized Knowledge Abstraction [14] layer in semantic web technologies has emerged as a potential hindrance to the facilitation of knowledge dissemination and access on the web. A workgroup has been recently started with the purpose of analyzing the requirement for knowledge abstraction and making an explicit recommendation to the W3 consortium to develop and promote a Knowledge Abstraction standard as part of their knowledge exchange protocols.

User Centered Engineering (UE)

User centered design methods have become increasingly adopted in modern engineering and design, not only for software, but any type of product development as well [11] In this approach, 'User requirements' are central to the system lifecycle, and user involvement is 'wired' into the development process via the constant elicitation of needs, desires and considering all the feedback as input to the development cycle. Overall 'principles of good design' according to this approach [12] include simplifying the structure of tasks, increasing visibility of conceptual design and system logic, valuing user feedback and provisions to handle errors constructively. Ontology Engineering methodologies seem to lack a well defined UE perspective, although from informal exchanges with peers it appears that research in this directly is currently being undertaken.

V. CONCLUSION AND RECOMMENDATIONS

In order for Ontology Engineering methodologies to evolve to serve modern and future systems development, they will benefit from the integration of activities and tasks that have consolidated from years of practice in other related engineering disciplines, such as SE, KE and UE. In this paper we identify Requirements Analysis, Knowledge Abstraction and User Centered Design activities and principles as candidates for such inclusion. It is recommended that a more systematic evaluation is undertaken with a view to standardize their formal integration in OEM, and gain support from W3 consortium. Future research in this area should focus on impact and modalities of such systematic integration of the above men into one over arching, portable and lightweight ontology engineering framework.

A Satellite Collision Analysis During Orbit Deployment

Manop Aorpimai and Peerawat Artitthang
Department of Control and Instrumentation Engineering
Mahanakorn University of Technology, Bangkok, Thailand 10530

***Abstract*—This paper presents a relative motion analysis of satellites after separation from the same launch vehicle. It poses a more instructive geometry of the motion profile than conventional methods. Collision between spacecraft after a few orbital periods is theoretically possible, although they are separated at different time, and into different orbits. A novel criterion for collision-free orbit deployment is proposed, where the incremental velocities can be assigned for all satellites in a formation system with a safety margin guaranteed.**

I. INTRODUCTION

Recently, the risk of collision in space has been of high concern, especially for satellites orbiting in Low-Earth Orbit ($<1,000\,km$ altitude) where most space missions are being performed very actively. With a velocity of several kilometers per second, a millimeter-across debris can seriously harm an expensive satellite or even a space-walking man. A number of researchers have systematically studied the probability of the collision between satellites and space debris, both natural and man-made ones. Rigorous statistical mathematics are employed to predict the chance for collisions [1-3]. A similar approach has been applied for satellite and space tether collision prediction and avoidance [4].

There is another scenario that has a potential to cause a catastrophe in space, namely, the collision between spacecraft during their orbit deployment. The chance for collision is trivial when the number of satellites in the system is small, and little attention has been paid to this in the past. For future missions, however, a system comprised of multiple satellites coordinated in a close formation will become more common, as it is believed to help increase the system flexibility as well as reducing the total cost of the mission.

The deployment of these satellites from a single rocket (see, for example, figure 1) can potentially cause collision between spacecraft. Unfortunately, very few works have been reported on the analysis of the collision in this case, and none of them covers all possibilities for collision. The deployment strategy for multiple secondary payloads on the MLV-05 mission [5], for example, pays attention only on the along-track component of the incremental velocity vector (ΔV) at the deployment instance. It assumes that the radial and cross-track component will not affect the orbital period and hence the chance for collision. Ramanan [6] proposed a collision-free deployment strategy. His first assumption is that two satellites, S_1 and S_2, which are separated at the same time with different velocities will come back to exactly rendezvous again if the orbital period $P_1 = nP_2$ where $n = l$ and $l = 1,2,3,...$ and when $n = 1/k$ where $k = 1,2,3,...$ Therefore, his proposed strategy is simply to avoid such condition.

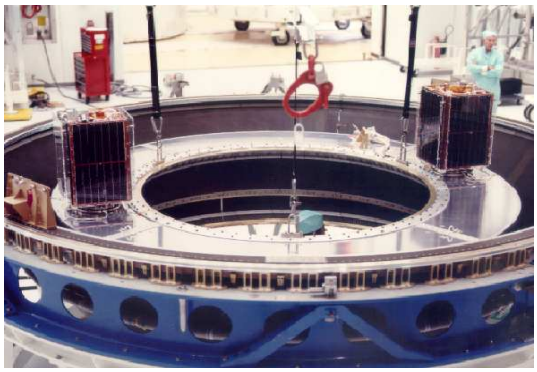

Figure 1. Multiple small satellites attached on the same launch vehicle

In this paper, it will be pointed out that, whatever the differential orbital period between satellites is, their relative motion which is closely related to both along-track and radial velocity components, can bring the satellites to a dangerously close approach. The closed-form solution proposed in this paper gives a more instructive description of the relative motion between satellites than the classic Clohessy-Wiltshire equations [7]. It then leads to a useful criterion for collision-free orbit deployment.

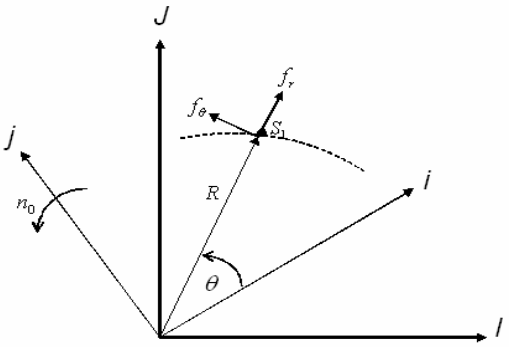

Figure 2. Coordinate System

II. ORBITAL DYNAMICS

Consider the motion of a satellite in the coordinate system shown in figure 2. (I, J) is an inertial frame with the origin at the centre of the Earth, and (i, j) is a rotating coordinate system which rotates with a constant angular rate n_0.

The equations of in-plane motion of the satellite viewed from the rotating coordinates can be derived as [8]

$$\ddot{R} - R\left(n_0 + \dot{\theta}\right)^2 + \frac{\mu}{R^2} = f_r \tag{1}$$

$$R\ddot{\theta} - 2\dot{R}\left(n_0 + \dot{\theta}\right)^2 = f_\theta \tag{2}$$

where R and θ are radius and phase of the satellite measured in the rotating frame, and f_r and f_θ are accelerations applied along the radial and along-track directions, respectively. μ is the gravitational parameter which is defined through $\mu \cong R_0^3 n_0^2$, where R_0 and n_0 are the orbital radius and frequency of a reference circular orbit, respectively. If we assume that the orbital radius of a satellite is in the vicinity of R_0, i.e. $r \ll R_0$, equations (1) and (2) can be linearised to first order approximation in r to give

$$\ddot{r} - 2R_0 n_0 \dot{\theta} - 3n_0^2 r = f_r \tag{3}$$

$$\ddot{\theta} + 2n_0 \dot{r} = f_\theta \tag{4}$$

If the applied accelerations are constant, both along the radial and along-track directions, equations (3) and (4) can be integrated to give

$$r = \left(\frac{f_r}{n_0^2} + \frac{2f_\theta t}{n_0}\right) + \Delta a_0 - R_0 e_0 \cos\left(n_0 t - \omega_0\right) \tag{5}$$

$$\begin{aligned}\theta = &-\left(\frac{f_r t}{R_0 n_0} + \frac{3}{2}\frac{f_\theta t^2}{R_0}\right) - \frac{3}{2}\frac{n_0}{R_0}\Delta a_0 t + 2e_0 \sin\left(n_0 t - \omega_0\right) \\ &+ \theta_0 - \left(\frac{2\dot{r}_0}{R_0 n_0} - \frac{4f_\theta}{R_0 n_0^2}\right)\end{aligned} \tag{6}$$

where

$$\Delta a_0 = \left(\frac{2R_0\dot{\theta}_0}{n_0} + 4r_0\right) \tag{7}$$

$$e_0 = \sqrt{\left(\frac{f_r}{R_0 n_0^2} + \frac{2\dot{\theta}_0}{n_0} + \frac{3r_0}{R_0}\right)^2 + \left(\frac{\dot{r}_0}{R_0 n_0} - \frac{2f_\theta}{R_0 n_0^2}\right)^2} \tag{8}$$

$$\omega_0 = \tan^{-1}\left(\frac{\dot{r}_0 n_0 - 2f_\theta}{3r_0 n_0^2 + 2\dot{\theta}_0 R_0 n_0 + f_r}\right) \tag{9}$$

The quantities in equations (7)-(9) represent the differential mean radius, eccentricity and argument of perigee at $t = 0$, respectively. Note that for the linerised dynamics, the motion caused by the acceleration component along the cross-track direction is de-coupled from the in-plane motion, and it expresses only simple harmonics oscillation [7].

III. COLLISION ANALYSIS

A spring mechanism is typically employed to separate each small satellite from the launch vehicle. The incremental velocity applied on the satellite can be assumed to be impulsive. The motion of the satellite, S_1, after the separation, relative to the launch vehicle that is orbiting in a circular orbit, can be found from equations (5)-(9) as

$$r = \Delta a_0 - R_0 e_0 \cos\left(n_0 t - \omega_0\right) \tag{10}$$

$$\theta = -\left(\frac{2\Delta V_{r1}}{R_0 n_0} + \frac{3}{2}\frac{n_0}{R_0}\Delta a_0 t - 2e_0 \sin\left(n_0 t - \omega_0\right)\right) \tag{11}$$

where

$$\Delta a_0 = \frac{2\Delta V_{\theta 1}}{n_0} \tag{12}$$

$$e_0 = \sqrt{\left(\frac{2\Delta V_{\theta 1}}{R_0 n_0}\right)^2 + \left(\frac{\Delta V_{r1}}{R_0 n_0}\right)^2} \tag{13}$$

$$\omega_0 = \tan^{-1}\left(\frac{\Delta V_{r1}}{2\Delta V_{\theta 1}}\right) \tag{14}$$

where ΔV_{r1} and $\Delta V_{\theta 1}$ are the incremental velocity components in the radial and along-track directions, respectively. Note that θ_0 and r_0 are zero, because the satellite is initially sitting on the launch vehicle.

The other satellites in the system may be deployed either at the same or different times after S_1. The relative motion between satellites can be described by differencing their relative motion with respect to the reference orbit. For example, if only the first two satellites, S_1 and S_2, are concerned, their relative motion will appear as an epicycle traveling with a constant along-track velocity. By applying equations (10)–(14), the centre of the epicycle $\left(r_{c0}, \theta_{c0}\right)$ is defined by the conditions at the epoch when S_2 is separated as

$$r_{c0} = \frac{2\delta V_\theta}{n_0} + 4r_{1t_2} \tag{15}$$

$$\theta_{c0} = \theta_{1t_2} - \frac{2\delta V_r}{R_0 n_0} \tag{16}$$

where δV_r and δV_θ are the differential applied velocities between the satellites. r_{1t_2}, θ_{1t_2} are the relative separation at t_2 when the second satellite is deployed. The radial amplitude of the epicycle is $R_0\delta e_0$ and the along-track amplitude is $2\delta e_0$, where δe_0 is the difference in eccentricity between the satellites orbits:

$$\delta e_0 = \sqrt{\left(\frac{2\delta V_\theta}{R_0 n_0} + \frac{3r_{1t_2}}{R_0}\right)^2 + \left(\frac{\delta V_r}{R_0 n_0}\right)^2} \tag{17}$$

The relative along-track drift rate is constant at

$$\delta\dot{\theta} = -\left(\frac{3\delta V_\theta}{R_0} + \frac{6n_0\delta r_{1t_2}}{R_0}\right) \tag{18}$$

This traveling epicycle can cause dangerously close approach, even though the two satellites have been deployed into orbits with an along-track separation and different orbital period. To visualise this, consider the relative motion between satellites in figure (3). In figure (3a), both satellites are separated at the same time, but a smaller along-track velocity has been applied on the second spacecraft. Obviously, it will appear to move forwards relative to the first satellite as its orbital period is shorter. Figure (3b) shows the motion when the second satellite is separated with the same differential velocity, but 10 seconds after the first satellite. We can see that the epicycle moves forward with the same rate in both cases. However, the difference in the eccentricity of the orbits, and the epoch of the separation cause the tail of the epicycle to start from the left-hand side. A collision occurs after 3 orbital periods, when the second satellite starts to move relatively rightward.

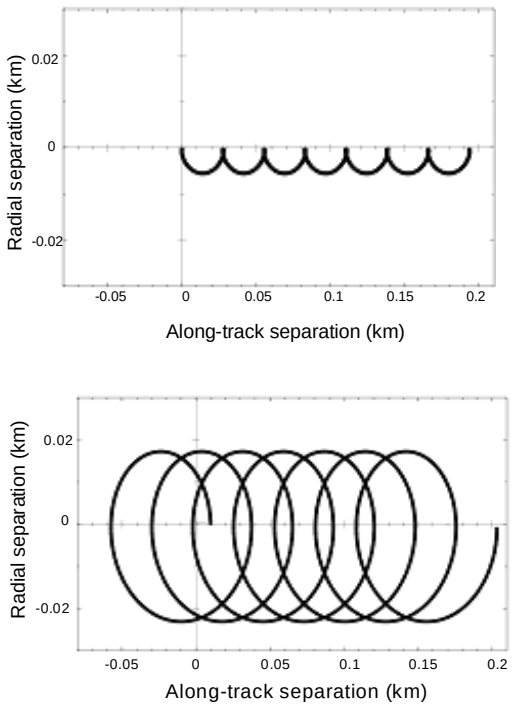

Figure 3. Relative motion between two satellites after orbit deployment

IV. COLLISION-FREE ORBIT DEPLOYMENT STRATEGY

So far, the cause of collision described above has never been paid attention, because its chance is trivial in practice, especially when the number of satellites in the system is small. However, the chance can potentially increase in the case of multiple satellite system, and when each satellite is equipped with some elongated parts.

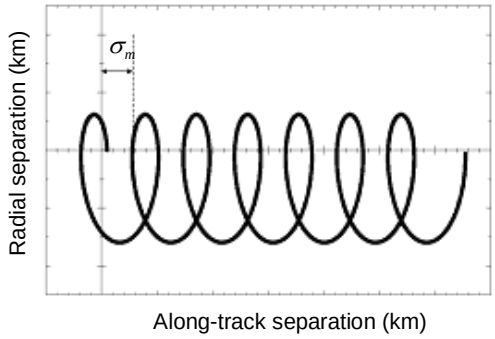

Figure 4. The safety margin for collision-free orbit deployment

In order to guaranteed that the spacecraft will not come back to collide, an adequate margin of closest approach after one orbital period (denoted by σ_m in figure (4)) can be assigned. From the shape and traveling velocity of the epicycle in equations (15)-(18), the criteria for the collision-free deployment can be set as

$$\left(\theta_{c0} - 2\delta e_0 + \frac{2\pi\delta\dot{\theta}}{n_0}\right) \le \sigma_m \tag{19}$$

It can be written in terms of differential incremental velocity as

$$-\left[\left(\theta_{1t_2} - \frac{12\pi r_{1t_2}}{R_0}\right) + \left(\frac{6\pi\delta V_\theta}{R_0 n_0} + \frac{2\delta V_r}{R_0 n_0}\right) + 2\sqrt{\left(\frac{2\delta V_\theta}{R_0 n_0} + \frac{3r_{1t_2}}{R_0}\right)^2 + \left(\frac{\delta V_r}{R_0 n_0}\right)^2}\right] \le \sigma_m \tag{20}$$

If the margin is zero the spacecraft will collide after one orbit. Note that this margin must have the same sign as the relative velocity, and if it is of the opposite sign to the relative velocity then there is a chance for collision as illustrated in figure (2b). When a safety margin is assigned, the differential velocity required for collision-free orbit deployment can be immediately worked out from equation (20).

If the satellites are separated simultaneously with only along-track velocities are applied, the differential incremental velocity will be proportional to the closest approach, and the criterion becomes

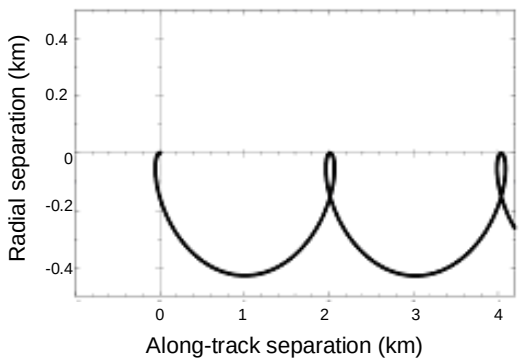
$$\delta V_\theta = \Delta V_{\theta 1} - \Delta V_{\theta 2} \le \frac{\sigma_m n_0}{6\pi + 4} \tag{21}$$

V. RESULTS

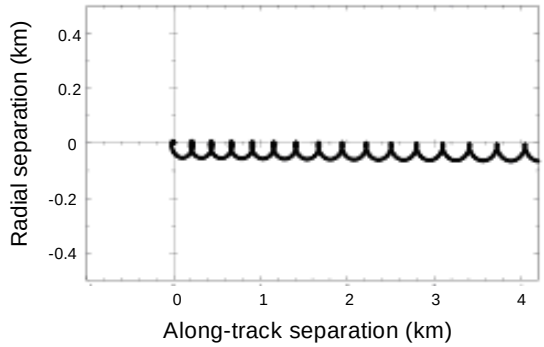
To validate the collision-free criteria proposed above, the deployment of two satellites to form a formation flying mission around a 700km altitude orbit is assumed. The closest approach between spacecraft is not allowed to be closer than 200 m. If the incremental along-track velocity assigned for the first satellite is $\Delta V_1 = 1.08 m/s$, the applied velocity for the second satellite can be calculated from equation (21) to give $\Delta V_{\theta 2} < 1.066 m/s$.

The errors in velocity magnitude and direction due to spring mis-alignment and the error of the launch vehicle heading can also be taken into account in the calculation. For example, it is possible that the velocity gain from the separation springs for both spacecraft can give an error up to 5% from their nominal values, and the combined error from the delta-V vector mis-alignment and the launcher's heading error can be up to 1 degree. The worst case scenario will occur when $\Delta V_{\theta 1}$ becomes smallest, i.e. $\Delta V_{\theta 1} = (\Delta V_1 - 0.05\Delta V_1)\cos(1^\circ)$, and $\Delta V_{\theta 2}$ becomes largest, i.e. $\Delta V_{\theta 2} = (\Delta V_2 + 0.05\Delta V_2)$, which will give the smallest σ_m. Note that there will be a radial velocity component applied on S_1 with an amount of $\Delta V_{r1} = (\Delta V_1 - 0.05\Delta V_1)\sin(1^\circ)$ in the worst case. From the given mission constraints, the incremental velocity required for S_2 can be calculated from equation (20), with $\theta_{1t_2} = r_{1t_2} = 0$ as both satellites are separated at the same time, and yields $\Delta V_2 < 0.977 m/s$.

By using this incremental delta-V, the relative motions between the spacecraft in nominal and worst cases are shown in figure (5a) and (5b), respectively. In figure (5a), S_2 moves away from S_1 with a larger excursion in the nominal situation, and the closest approach during the second orbit is about 2 km. In the worst case situation shown in figure (5b), however, the closest margin is guaranteed at 200 m as required.



(a)



(b)

Figure 5. The motion after separation with a margin guaranteed

VI. CONCLUSIONS

The presented analysis of relative motion shows its simplicity and instructive geometry. Although a system of only two satellites is given in the example, the proposed criteria can be applied directly to the system that is comprised of multiple satellites. Any kind of orbit separation mechanism and structure can also adopt this criterion without any limitation. This gives a great benefit to new-generation launch vehicles when the design will be dedicated for multiple small satellites.

TPM1-1-5	**Simulations and Visualization of Electrostatic Field Strength Caused by Electrostatic**	**679**
2:20 PM	**Voltage Source in Homogeneous Material** Atthapol Wangsotorn[1], Pharkphum Direkpoke[2], Somchart Roongruangsorakarn[1], Kraisorn Chaisaowong[1,2,3] [1]*Department of Computer and Information Science,* *King Mongkut's Institute of Technology North Bangkok, Bangkok, Thailand* [2]*Department of Electrical Engineering, King Mongkut's Institute of Technology North Bangkok* [3]*Institute of Imaging & Computer Vision, RWTH Aachen University, Germany*	

1:00 PM - 3:00 PM **Session TPM1-3** **Thursday,10 May 2007**

Mobile Communication Technology

Chairperson : Zia Nadir, Sultan Qaboos University

TPM1-3-1 **Performance Study of CFP Contention Resolution Algorithm for Wireless** **683**
1:00 PM **Communication System**
Suvit Nakpeerayuth, Warakorn Srichavengsup, Lunchakorn Wuttisittikulkij
Department of Electrical Engineering, Faculty of Engineering,
Chulalongkorn University, Bangkok, Thailand

TPM1-3-2 **Computer-based 2D Simulations of SAR in Inhomogeneous Biological Domain Model** **687**
1:20 PM **Caused by Isotropic Antenna at 900 MHz and 1800 MHz**
Pharkphum Direkpoke[1], Atthapol Wangsotorn[2], and Kraisorn Chaisaowong[1,2,3]
[1]*Department of Electrical Engineering, Faculty of Engineering,*
King Mongkut's Institute of Technology North Bangkok, Bangkok, Thailand
[2]*Department of Computer and Information Science, Faculty of Applied Science,*
King Mongkut's Institute of Technology North Bangkok, Bangkok, Thailand
[3]*Institute of Imaging & Computer Vision, RWTH Aachen University, Germany*

TPM1-3-3 **Adaptive Channel Equalizer Design for Uplink WCDMA Rake Receiver** **691**
1:40 PM T. Phoopattanakul, W. Saenghiranwattana, K. Ruangsa-ad, C. Charoenlarpnopparut,
P. Boonyanant
Sirindhorn International Institute of Technology, Thammasat University, Thailand

TPM1-3-4 **Closed-Form Analysis of Equal Gain Combining for Wireless Communications** **695**
2:00 PM T.Phophongviwat[1], C.Chat-uthai[2]
[1]*Department of Electrical Power Engineering, Faculty of Engineering,*
Mahanakorn University of Technology, Bangkok, Thailand
[2]*Department of Electrical Engineering, Faculty of Engineering,*
King Mongkut's Institute of Technology Ladkrabang, Bangkok, Thailand

TPM1-3-5 **Artificial Immunity-Based Feature Extraction for Spam Detection** **698**
2:20 PM Burim Sirisanyalak, Ohm Sornil
Department of Computer Science,
National Institute of Development Administration, Bangkok, Thailand

TPM1-3-6 **Modification Of An Urban Area Okumura-Hata Propagation Model Suitable For** **702**
2:40 PM **Salalah-Oman**
Z. Nadir, N. Elfadhil, F. Touati, B. Suhail, M. Jamal, M. Abdulrahman,
Department of ECE, Sultan Qaboos University, Muscat, Sultanate of Oman

1:00 PM - 2:20 PM **Session TPM1-5** **Thursday,10 May 2007**

Communication Networks

Chairperson : Chalie Charoenlarpnopparut : Sirindhorn International Institute of Technology

TPM1-5-1 **A Design of Backpressure Scheme in Traffic Shaping over High speed network** **706**
1:00 PM Somchai Lekcharoen, Srisawad Yongyut
Faculty of Information Technology, Rangsit University, Bangkok, Thailand

TPM1-5-2	**Multicast Improvement Bandwidth Utilization in Inter-ring RPR Topology**	**710**
1:20 PM	Wuttichai Kwanmetakun, Pisai Setthawong, Surat Tanterdtid *Department of Telecommunications Science, Faculty of Science and Technology,* *Assumption University, Thailand*	
TPM1-5-3	**The Optimum route by QoS Based on Genetic Algorithms (QGAs)**	**714**
1:40 PM	Jittanun Kulsiri, Suvepon Sittichivapak, Kriengkai Vonglodjanaporn *Department of Telecommunication Engineering, Faculty of Engineering,* *King Mongkut's Institute of Technology Ladkrabang, Bangkok, Thailand*	
TPM1-5-4	**TCP-Friendliness Definition Revision & Implementation for Multi-Rate Multicast**	**718**
2:00 PM	**Congestion Control** Somnuk Puangpronpitag[1], Suchart Kummanee[2] [1]*Computer Science, Faculty of Informatics, Mahasarkham University, Thailand* [2]*Department of Computer Science, Faculty of Science,Khon Kaen University, Thailand*	

3:20 PM - 4:40 PM	**Session TPM2-1** **Antennas and Propagations** Chairperson : Danai Torrungrueng, Asian University	**Thursday,10 May 2007**
TPM2-1-1	**Design of Dual Wide-band Slot Antenna Fed by CPW**	**722**
3:20 PM	P. Pommas[1], N. Anantrasirichai[1], P. Rakluea[2], T. Wakabayashi[3] *Research Center for Communications and Information Technology (ReCCIT),* *King Mongkut's Institute of Technology Ladkrabang, Bangkok, Thailand* [2]*Department of Electronic and Telecommunication Engineering, Faculty of Engineering,* *Rajamangala University of Technology Thanyaburi, Pathumthanee, Thailand* [3]*School of Information Science and Technology, Tokai University, Kanagawa, Japan*	
TPM2-1-2	**A Compact U-Shaped Cross-Sectional Antenna on a U-Shaped Ground Plane for WLAN**	**726**
3:40 PM	Duang-arthit Srimoon[1], Chuwong Phongcharoenpanich[2], Monai Krairiksh[2] [1]*School of Computer Engineering, College of Engineering,* *Rangsit University, Pathumthani, Thailand* [2]*Faculty of Engineering & Research Center for Communications and Information Technology,* *King Mongkut's Institute of Technology Ladkrabang, Bangkok, Thailand*	
TPM2-1-3	**Fractal array antenna with NP generator model**	**730**
4:00 PM	Chatree Mahatthanajatuphat, Prayoot Akkaraekthalin *Department of Electrical Engineering, Faculty of Engineering,* *King Mongkut's Institute of Technology North Bangkok, Bangkok, Thailand*	
TPM2-1-4	**A New Compact WLAN 2.4 GHz CPW-fed Slot Antenna with Inverted-F Shaped**	**734**
4:20 PM	**Tuning Stub** Prapoch Jirasakulporn[1], Sarawuth Chaimool[2], Prayoot Akkaraekthalin[2] [1]*Pathumwan Institute of Technology, Bangkok, Thailand* [2]*Department of Electrical Engineering, Faculty of Engineering,* *King Mongkut's Institute of Technology North Bangkok, Bangkok, Thailand*	

3:20 PM - 4:40 PM | **Session TPM2-5** | **Thursday,10 May 2007**

Communication Systems 2

Chairperson : Usana Tuntoolavest, Kasetsart University

TPM2-5-1 **Throughput Analysis for Orthogonal Diversity of CSMA/CA Protocol by SFH/MC DS-CDMA** **737**
3:20 PM
Pichet Roumsamug[1], Pisakorn Sittiwatjana[2], Suvepon Sittichivapak[1]
[1]Department of Telecommunication Engineering, Faculty of Engineering,
King Mongkut's Institute of Technology Ladkrabang, Bangkok, Thailand
[2]Prince of Songkhla University, Phuket Campus, Phuket, Thailand

TPM2-5-2 **Users Capacity Increment of MLC-GSM Over Rayleigh Fading Channel** **741**
3:40 PM
Phichet Moungnoul, Wiphada Inkiew
Research Center for Communication and Information Technology,
King Mongkut's Institute of Technology Ladkrabang, Bangkok, Thailand

TPM2-5-3 **Proposal of PAPR Reduction Method for OFDM Signal without Side Information** **745**
4:00 PM
Pornpawit Boonsrimuang[1], Pisit Boonsrimuang[1], Kazuo Mori[2], Tawil Paungma[1], Hideo Kobayashi[2]
[1]Department of Telecommunication Engineering, Faculty of Engineering,
King Mongkut's Institute of Technology Ladkrabang, Bangkok, Thailand
[2]Division of Electrical and Electronic Engineering,
Graduate School of Engineering, Mie University, Japan

TPM2-5-4 **Interference Effect Comparison between IS-95B and CDMA2000 Cellular System over Nakagami Fading Channel** **749**
4:20 PM
Naphat Sutthaphol, Phichet Moungnoul
Research Center for Communication and Information Technology (ReCCIT),
King Mongkut's Institute of Technology Ladkrabang, Bangkok, Thailand

3:20 PM - 5:00 PM | **Session TPM2-10** | **Thursday,10 May 2007**

SS : Microwave and Antennas 1

Chairperson : Jun-ichi Takada, Tokyo Institute of Technology

TPM2-10-1 **Measurement Techniques of Transmissions from Ultra Wideband Devices** **753**
3:20 PM
Jun-ichi Takada
Graduate School of Science and Engineering, Tokyo Institute of Technology, Tokyo, Japan

TPM2-10-2 **Experimental Study and Analysis of Antenna Effects for UWB Radio Transmission** **757**
3:40 PM
Sanit Teawchim[1], Sathaporn Promwong[1], Jun-ichi Takada[2]
[1]Department of Information Engineering, Faculty of Engineering,
King Mongkut's Institute of Technology Ladkrabang, Bangkok, Thailand
[2]Graduate School of Science and Engineering, Tokyo Institute of Technology, Tokyo, Japan

TPM2-10-3 **Planar Source Characteristics Analysis for Wave Iterative Method Simulation** **761**
4:00 PM
Somsak Akatimagool, Sommart Kamkleing
Department of Teaching Training in Electrical Engineering, Faculty of Technical Education,
King Mongkut's Institute of Technology North Bangkok, Bangkok, Thailand

TPM2-10-4	**The Generalized Constant Circuit-Node Q Circles on the Extended T-Chart**	**765**
4:20 PM	P. Y. Chou, D. Torrungrueng *Department of Electrical and Electronic Engineering,* *Faculty of Engineering and Technology, Asian University, Chon Buri, Thailand*	
TPM2-10-5	**A Microstrip-Coplanar Waveguide Tight Coupler for a Single-Layer Substrate**	**769**
4:40 PM	Mitchai Chongcheawchamnan, Waikoon Sangworn, Ratthaya Suwanbunyaporn, Ravee Phromloungsri *Research Center for Electromagnetic Wave Applications (RCEWs),* *Telecommunication Engineering Department,* *Mahanakorn University of Technology, Bangkok, Thailand*	
8:30 AM - 10:10 AM	**Session FAM1-1** **Power Line Comm./ RFID** Chairperson : Chalie Charoenlarpnopparut, Sirindhorn International Institute of Technology	**Friday,11 May 2007**
FAM1-1-1	**Performance of Power Line Communication using Direct- Sequence Code Division**	**773**
8:30 AM	**Multiple Access with Turbo Coded** S. Chanakarn, C. Banjangkaprasert, N. Anantrasirichai *Research Center for Communications and Information Technology (ReCCIT),* *King Mongkut's Institute of Technology Ladkrabang, Bangkok, Thailand*	
FAM1-1-2	**TCP/IP Protocol over Power Line Communication System Contaminated with**	**777**
8:50 AM	**Impulsive noise** Oraya Rattanakanokkan, Suvepon Sittichivapak, Kriengkai Vonglodjanaporn *Department of Telecommunication Engineering, Faculty of Engineering,* *King Mongkut's Institute of Technology Ladkrabang, Bangkok, Thailand*	
FAM1-1-3	**Chaotic Direct Sequence Spread Spectrum for Power line Datacommunication**	**781**
9:10 AM	Narumon Thummakerd[1], Suvepon Sittichivapak[1], Kidsanapong Puntsri[2] [1]*Faculty of Telecommunication Engineering*, *King Mongkut's Institute of Technology Ladkrabang, Bangkok, Thailand* [2]*Department of Electronics and Telecommunication Engineering*, *Rajamangala University of Technology Phranakhon, Bangkok, Thailand*	
FAM1-1-4	**Evaluation Methods for Active RFID Equipments in Road Access Services**	**785**
9:30 AM	L. Kovavisaruch, T. Sanpechuda, J. Wisanmongkol, C. Mitrepant *National Electronics and Computer Technology Center (NECTEC), Pathumthani, Thailand*	
FAM1-1-5	**Data Recording with FAT16 in Removable Media of RFID Handheld Reader**	**789**
9:50 AM	Anukool Noymai, Urachada Ketprom, Chaichana Mitrpant *National Electronics and Computer Technology Center (NECTEC), Pathumthani, Thailand*	

8:30 AM - 10:10 AM **Session FAM1-5** **Friday,11 May 2007**

Mobile Communication Networks

Chairperson : Phongsak Keeratiwintakorn, King Mongkut's Institute of Technology North Bangkok

FAM1-5-1 **Performance Improvement of Paging Extensions for Mobile Internet Protocol based on** **793**
8:30 AM **Regional Registration and Multicasting**
Andrianus Yofy, Watit Benjapolakul
Department of Electrical Engineering, Chulalongkorn University, Bangkok, Thailand

FAM1-5-2 **Adaptive Protocol with Channel Variance Estimations for Cooperative Communications** **797**
8:50 AM
Chaiyod Pirak
Department of Teacher Training in Electrical Engineering,
King Mongkut's Institute of Technology North Bangkok, Bangkok, Thailand

FAM1-5-3 **Robust Ad Hoc Routing Protocol using Relative Mobility Information** **801**
9:10 AM
Suksun Mahakittikun, Peerapon Siripongwutikorn
Department of Computer Engineering,
King Mongkut's University of Technology Thonburi, Bangkok, Thailand

FAM1-5-4 **A QoS-Based Dynamic Source Routing for Multimedia Service in Mobile** **805**
9:30 AM **Ad Hoc Networks**
Wayan Mustiksa[1], Sakchai Thipchaksurat[1], Ruttikorn Varakulsiripunth[1], Hiroshi Ishii[2]
[1]Research Center for Communications and Information Technology (ReCCIT),
King Mongkut's Institute of Technology Ladkrabang, Bangkok, Thailand
[2]Department of Communication Engineering,
School of Information Technology and Electronics, Tokai University, Japan

FAM1-5-5 **Optimal Frequency Channel Assignment for WLANs Using Hybrid SIR and CSMA/CA** **809**
9:50 AM **Considerations**
Chutima Prommak, Boriboon Deeka
School of Telecommunications Engineering,
Suranaree University of Technology, Nakorn Ratchasima, Thailand

8:30 AM - 10:10 AM **Session FAM1-9** **Friday,11 May 2007**

Microwave Devices

Chairperson : Jaruek Jantree, Rajamangala University of Technology Suvarnabhumi

FAM1-9-1 **Compact Microstrip Two-layer Dual-Band Bandpass Filter Using Aperture-coupled** **813**
8:30 AM **SIR-Hairpin Resonator**
Sutatorn Promprathom[1], Jaruek Jantree[2], Sarawuth Chaimool[1], Prayoot Akkaraekthalin[1]
[1]Department of Electrical Engineering, Faculty of Engineering,
King Mongkut's Institute of Technology North Bangkok, Bangkok, Thailand,
[2]Department of Electrical Engineering, Faculty of Engineering and Architecture,
Rajamangala University of Technology Suvarnabhumi, Supanburi Campus, Thailand

FAM1-9-2	**Microwave Ablation Therapy for Lung Cancer using Open-Tip and Multi-Slot Coaxial**	**817**
8:50 AM	**Antenna**	
	D. Kiatkittisorn[1], M. Sangworasil[1,2], P. Phasukkit[1,2], S. Tungjitkusolmun[1,2]	
	[1]Faculty of Engineering,	
	King Mongkut's Institute of Technology Ladkrabang, Bangkok, Thailand	
	[2]Computer Research and Service Center,	
	King Mongkut's Institute of Technology Ladkrabang, Bangkok, Thailand	
FAM1-9-3	**Reducing Self Resonance Effect in High FrequencyInductors Using Capacitance**	**821**
9:10 AM	**Cancellation Technique**	
	K. Piboonwattanakit[1], V. Tarateeraseth[2], W. Khan-ngern[1]	
	[1]Research Center for Communications and Information Technology,	
	King Mongkut's Institute of Technology Ladkrabang, Bangkok, Thailand	
	[2]Srinakharinwirot University, Faculty of Engineering, Nakornnayok, Thailand	
FAM1-9-4	**A Minimized Bandpass Filter Using Two-Layers With Aperture-coupled for Microstrip**	**825**
9:30 AM	**Slow-Wave Open-Loop Resonator**	
	Apirada Namsang, Jaruek Jantree, Prayoot Akkaraekthalin	
	Department of Electrical Engineering, Faculty of Engineering,	
	King Mongkut's Institute of Technology North Bangkok, Bangkok, Thailand	
FAM1-9-5	**Bandwidth Enhancement of a CPW-Fed Rectangular Slot Antenna**	**829**
9:50 AM	P. Seangsae[1], N. Anantrasirichai[1], J. Nakasuwan [2], T. Wakabayashi[3]	
	[1]Research Center for Communications and Information Technology (ReCCIT),	
	King Mongkut's Institute of Technology Ladkrabang, Bangkok, Thailand	
	[2]Department of Electronic and Telecommunication Engineering, Faculty of Engineering,	
	Rajamangala University of Technology Thanyaburi, Pathumthanee, Thailand	
	[3]School of Information Science and Technology, Tokai University, Kanagawa, Japan	

8:30 AM - 10:10 AM	**Session FAM1-10**	**Friday,11 May 2007**
	SS : Microwave and Antennas 2	
	Chairperson : Rangsan Wongsan, Suranaree University of Technology	
FAM1-10-1	**Elliptical Patch Antenna Radiating Unidirectional Beam with Circular Polarization for**	**833**
8:30 AM	**Reader of RFID at UHF Band**	
	Rattapong Suwalak, Chuwong Phongcharoenpanich	
	Research Center for Communications and Information Technology (ReCCIT),	
	King Mongkut's Institute of Technology Ladkrabang, Bangkok, Thailand	
FAM1-10-2	**Parametric Study of a Vertically Polarized Concentric Circular Ring Antenna above**	**837**
8:50 AM	**the Reflector for High Gain Applications**	
	Souphanna Vongsack[1], Krittaya Chawanonphithak[1], Chuwong Phongcharoenpanich[1],	
	Sompol Kosulvit[1], Toshio Wakabayashi[2]	
	[1]Research Center for Communications and Information Technology,	
	King Mongkut's Institute of Technology Ladkrabang, Bangkok, Thailand	
	[2]School of Engineering, Tokai University, Kanagawa, Japan,	

FAM1-10-3	**Microwave-Based Durian Maturity Determination Using Microstrip Patch Antennas**	**841**
9:10 AM	Navapadol Kittiamornkul[1], Kamon Jiraseriamornkul[1], Kosin Chamnongthai[1,] Monai Krairiksh[2] [1]*Department of Electronic and Telecommunication Engineering,* *King Mongkut's University of Technology Thonburi, Bangkok, Thailand* [2]*Department of Telecommunication Engineering, Faculty of Engineering,* *King Mongkut's Institute of Technology Ladkrabang, Bangkok, Thailand*	
FAM1-10-4	**Interdigital Microstrip Resonator Sensor for Complex Permittivity Measurement**	**845**
9:30 AM	Somporn Seewattanapon[1], Tanee Somwong[2], Prayoot Akkaraekthalin[1] [1]*Department of Electrical Engineering, Faculty of Engineering,* *King Mongkut's Institute of Technology North Bangkok, Bangkok, Thailand* [2]*Department of Electrical Engineering, Faculty of Engineering and Architecture,* *Rajamangala University of Technology Suvarnabhumi, Nonthaburi, Thailand*	
FAM1-10-5	**A Miniaturized Dual-mode Bandpass Filter using Triangular Loop Resonator**	**849**
9:50 AM	Supachai Chotjit, Sarawuth Chaimool, Prayoot Akkaraeakthalin *Department of Electrical Engineering, Faculty of Engineering,* *King Mongkut's Institute of Technology North Bangkok, Bangkok, Thailand*	

10:30 AM - 12:10 AM	**Session FAM2-1**	**Friday,11 May 2007**
	Modulation and Channel Analysis	
	Chairperson : Keattisak Sripimanwat, National Electronics and Computer Technology Center	
FAM2-1-1	**Performance of MPSK Modulation in combined Flat Scintillation and**	**853**
10:30 AM	**Frequency-Selective Fading Channel for Satellite Mobile Communication System** N. Boonsongkusoljit, P.Supnithi *Research Center for Communications and Information Technology,Faculty of Engineering,* *King Mongkut's Institute of Technology Ladkrabang, Bangkok, Thailand*	
FAM2-1-2	**On the Interference Cancellation of OFDM System for Aeronautical Communication**	**857**
10:50 AM	Panit Lamun, Montree Kumngern, Phichet Moungnoul, Kobchai Dejhan *Faculty of Engineering and Research Center for Communication and Information Technology,* *King Mongkut's Institute of Technology Ladkrabang, Bangkok, Thailand*	
FAM2-1-3	**On the Performance of Adaptive MIMO-OFDM Systems over Severe Mobile Fading**	**860**
11:10 AM	**Channels** Hyundong Kim[1], Sangho Choe[2] [1]*The Catholic University of Korea, Bucheon-si, Korea* [2]*Beijing University of Posts and Telecommunications, Beijing, China*	
FAM2-1-4	**Proposal of Multi-level QAM-OFDM System with IDSI and IDAR Methods in Satellite**	**864**
11:30 AM	**Channel** Pisit Boonsrimuang[1], Kazuo Mori[2], Tawil Paungma[1], Hideo Kobayashi[2] [1]*Department of Telecommunication Engineering, Faculty of Engineering,* *King Mongkut's Institute of Technology Ladkrabang, Bangkok, Thailand* [2]*Division of Electrical and Electronic Engineering,* *Graduate School of Engineering, Mie University, Japan*	

FAM2-1-5	**QPSK Modulator Based On Phase Locked Loop**	**868**
11:50 AM	P. Wisartpong, J. Koseeyaporn, P.Wardkein *Department of Telecommunication Engineering, Faculty of Engineering,* *King Mongkut's Institute of Technology Ladkrabang, Bangkok, Thailand*	

10:30 AM - 12:10 AM	**Session FAM2-5** **UWB Channels** Chairperson : Sathaporn Promwong, King Mongkut's Institute of Technology Ladkrabang	**Friday,11 May 2007**
FAM2-5-1	**BER Performance of UWB Communications with Matched Filter and Correlation**	**872**
10:30 AM	**Receivers** Kultharee Teplee[1], Pichaya Supanakoon[1,2], Sathaporn Promwong[1,2], Jun-ichi Takada[3] [1]*Department of Information Engineering, Faculty of Engineering,* *King Mongkut's Institute of Technology Ladkrabung, Bangkok, Thailand* [2]*Research Center for Communications and Information Technology (ReCCIT),* *King Mongkut's Institute of Technology Ladkrabung, Bangkok, Thailand* [3]*Graduate School of Science and Engineering, Tokyo Institute of Technology, Tokyo, Japan*	
FAM2-5-2	**Modeling of Indoor UWB Channel by Using Finite Difference Time Domain Method**	**876**
10:50 AM	Phannipha Thaiwattanaporn[1], Pichaya Supanakoon[1,2], Sathaporn Promwong[1,2], Jun-ichi Takada[3] [1]*Department of Information Engineering, Faculty of Engineering,* *King Mongkut's Institute of Technology Ladkrabung, Bangkok, Thailand* [2]*Research Center for Communications and Information Technology (ReCCIT),* *King Mongkut's Institute of Technology Ladkrabung, Bangkok, Thailand* [3]*Graduate School of Science and Engineering, Tokyo Institute of Technology, Tokyo, Japan*	
FAM2-5-3	**Power Spectral Density Analysis of Ultra Wideband Signal Using Pulse Shape**	**880**
11:10 AM	**Modulation** Parinya Prommasuksakul[1], Pichaya Supanakoon[1,2], Sathaporn Promwong[1,2], Jun-ichi Takada[3] [1]*Department of Information Engineering, Faculty of Engineering,* *King Mongkut's Institute of Technology Ladkrabung, Bangkok, Thailand* [2]*Research Center for Communications and Information Technology (ReCCIT),* *King Mongkut's Institute of Technology Ladkrabung, Bangkok, Thailand* [3]*Graduate School of Science and Engineering, Tokyo Institute of Technology, Tokyo, Japan*	
FAM2-5-4	**Performance Investigation of UWB Rake Receiver in Realistic Indoor Channels**	**884**
11:30 AM	Worawoot Duangdeun, Monchai Chamchoy, Sathaporn Promwong *Faculty of Engineering, King Mongkut's Institute of Technology Ladkrabang, Bangkok, Thailand*	
FAM2-5-5	**Ultra Wideband Radio Propagation Channel with Corridor for Short Range Wireless**	**888**
11:50 AM	**Systems** Nisakorn Yingkajohn, Sathaporn Promwong, Pichaya Supanakoon *Department of Information Engineering, Faculty of Engineering,* *King Mongkut's Institute of Technology Ladkrabang, Bangkok, Thailand*	

1:00 PM - 3:00 PM **Session FPM1-1** **Friday,11 May 2007**

Communication Systems

Chairperson : Tanee Demeechai, Mahanakorn University of Technology

FPM1-1-1 **Modified Decision Feedback Adaptive Equalizer for Turbo Coded DS-CDMA Systems** **892**
1:00 PM
T. Udomsripaiboon[1], N. Sanpote[1], K. Sooksomsatarn[1], C. Benjangkaprasert[2]
[1]School of Information and Communication Technology ,
Narasuan University, Payao Campus, Payao,Thailand
[2]Research Center for Communications and Information Technology (ReCCIT),
King Mongkut's Institute of Technology Ladkrabang, Bangkok, Thailand

FPM1-1-2 **A Channel Estimation Method for Downlink STBC MC-CDMA System on Multi-Path** **896**
1:20 PM **Fading Channel**
Pattanapong Sookkaew, Montree Kumngern, Somyot Junnapiya, Kobchai Dejhan
Research Center for Communication and Information Technology,
King Mongkut's Institute of Technology Ladkrabang, Bangkok, Thailand

FPM1-1-3 **An Extend Bi-directional Arbitrated Decision Feedback Equalizer** **899**
1:40 PM
Samart Moodleah[1], Chawalit Benjangkaprasert[1], Keattisak Sripimanwat[2]
[1]Research Center for Communications and Information Technology (ReCCIT),
King Mongkut's Institute of Technology Ladkrabang, Bangkok, Thailand
[2]National Electronics and Computer Technology Center (NECTEC), Pathumthanee, Thailand

FPM1-1-4 **Narrowband Interference Suppression for UWB-TH System Based On Modified** **903**
2:00 PM **Template Waveform**
Eakaraj Pakdeechard, Monchai Chamchoy, Sathaporn Promwong
Faculty of Engineering, King Mongkut's Institute of Technology Ladkrabang, Bangkok, Thailand

FPM1-1-5 **A Survey on Non-Coherent QAM Receiver Structure in Noisy Channel** **907**
2:20 PM
Shahab Asoodeh, Alireza Rezazade
Department of Electrical and Computer Engineering, Shahid Behehsti University

FPM1-1-6 **Signal Transformation Using Harmonic Transform Based on OFDM** **911**
2:40 PM
Saiyan Saiyod, Sakchai Thipchaksurat, Ruttikorn Varakulsiripunth
Research Center for Communication and Information Technology (ReCCIT),
King Mongkut's Institute of Technology Ladkrabang, Bangkok, Thailand

1:00 PM - 3:00 PM **Session FPM1-5** **Friday,11 May 2007**

UWB Technology

Chairperson : Revee Phromloungsri, Mahanakorn University of Technology

FPM1-5-1 **Location Estimation Based on Modified TOA Measurements for UWB Network** **915**
1:00 PM
Tawatchai Jantaworn, Monchai Chamchoy, Sathaporn Promwong, Nikorn Sukutamtanti
Faculty of Engineering, King Mongkut's Institute of Technology Ladkrabang, Bangkok, Thailand

FPM1-5-2	**Accuracy Analysis of Focusing Resolution with TR EM Pulse Propagation for UWB**	**919**
1:20 PM	**Imaging Systems**	
	Tanaporn Payommai[1], Pichaya Supanakoon[1,2], Sathaporn Promwong[1,2], Nikorn Sukutamtanti[1], Jun-ichi Takada[3]	
	[1]Department of Information Engineering, Faculty of Engineering	
	[2]Research Center for Communications and Information Technology (ReCCIT), King Mongkut's Institute of Technology Ladkrabung, Bangkok, Thailand	
	[3]Graduate School of Science and Engineering, Tokyo Institute of Technology, Tokyo, Japan	
FPM1-5-3	**Performance Evaluation of Free Space Transmission Gain for Ultra Wideband Impulse**	**923**
1:40 PM	**Radio System**	
	Narongsak Manosittichai, Sathaporn Promwong	
	Department of Information Engineering, Faculty of Engineering, King Mongkut's Institute of Technology Ladkrabang, Bangkok, Thailand	
FPM1-5-4	**An Ultra-wideband CPW-Fed Elliptical Loop Slot Antenna**	**927**
2:00 PM	Rapeepan Keawon, Prayoot Akkaraekthalin, Vech Vivek	
	Department of Electrical Engineering, Faculty of Engineering, King Mongkut's Institute of Technology North Bangkok, Bangkok, Thailand	
FPM1-5-5	**Ultra Wideband Series-Fed Printed Dipole Antenna Arrays with a Log-periodic**	**931**
2:20 PM	**Structure**	
	Chittawan Choeysakul[1], Sarawuth Chaimool[2], Prayoot Akkaraekthalin[1,2]	
	[1]Communication Engineering, Thai-German Graduate School of Engineering, King Mongkut's Institute of Technology North Bangkok, Bangkok, Thailand	
	[2]Department of Electrical Engineering, Faculty of Engineering, King Mongkut's Institute of Technology North Bangkok, Bangkok, Thailand	
FPM1-5-6	**A Study of Interference Signal of Ultra Wideband to Wireless Local Areal Network**	**935**
2:40 PM	Pathamavadee Kositsakul, Sathaporn Promwong	
	Department of Information Engineering, Faculty of engineering, King Mongkut's Institute of Technology Ladkrabang, Bangkok, Thailand	

3:20 PM - 5:00 PM	**Session FPM2-1**	**Friday,11 May 2007**
	Antenna Technology	
	Chairperson : Chuwong Phongcharoenpanich, King Mongkut's Institute of Technology Ladkrabang	
FPM2-1-1	**Bandwidth Enhancement of a CPW-Fed Rectangular Slot Antenna**	**939**
3:20 PM	P. Seangsae[1], N. Anantrasirichai[1], J. Nakasuwan[2], T. Wakabayashi[3]	
	[1]Research Center for Communications and Information Technology (ReCCIT), King Mongkut's Institute of Technology Ladkrabung, Bangkok, Thailand	
	[2]Department of Electronic and Telecommunication Engineering, Faculty of Engineering, Rajamangala University of Technology Thanyaburi, Pathumthanee, Thailand	
	[3]School of Information Science and Technology, Tokai University, Kanagawa, Japan	

FPM2-1-2	**CPW-Fed Rectangular Slot Antenna with Tuning Stub for Dual Frequency**	**943**
3:40 PM	S. Kaewsupan[1], N. Anantrasirichai[1], P. Rakluea[2], T. Wakabayashi[3] *[1]Research Center for Communications and Information Technology (ReCCIT), King Mongkut's Institute of Technology Ladkrabung, Bangkok, Thailand* *[2]Department of Electronic and Telecommunication Engineering, Faculty of Engineering, Rajamangala University of Technology Thanyaburi, Pathumthanee, Thailand* *[3]School of Information Science and Technology, Tokai University, Kanagawa, Japan*	
FPM2-1-3	**Microstrip-Fed Acute Angle Wide-Slot Antenna**	**947**
4:00 PM	P. Wiriyacosol[1], C. Benjangkaprasert[1], N. Anatrasirichai[1], T. Wakabayashi[2] *[1]Research Center for Communications and Information Technology (ReCCIT), Department of Information Engineering, Faculty of Engineering, King Mongkut's Institute of Technology Ladkrabang, Bangkok, Thailand* *[2]School of Information Science and Technology, Tokai University, Kanagawa, Japan*	
FPM2-1-4	**Closed-form Expressions of Mutual Impedance between Perpendicular Thin Dipoles**	**951**
4:20 PM	T. Limpiti, M. Krairiksh *Research Center for Communications and Information Technology (ReCCIT), Department of Information Engineering, Faculty of Engineering, King Mongkut's Institute of Technology Ladkrabang, Bangkok, Thailand*	
FPM2-1-5	**Structural Analysis of Trapezoidal Dual Loop Antenna for Communication**	**955**
4:40 PM	**Performance Enhancement of LF-RFID** Supakit Kawdungta[1], Phairote Wounchoum[1], Chuwong Phongcharoenpanich[1], Danai Torrungrueng[2] *[1]Research Center for Communications and Information Technology, Department of Information Engineering, Faculty of Engineering, King Mongkut's Institute of Technology Ladkrabang, Bangkok, Thailand* *[2]Faculty of Engineering and Technology, Asian University, Chon Buri, Thailand*	
3:20 PM - 5:00 PM	**Session FPM2-5**	**Friday,11 May 2007**
	Communication Technology Chairperson : Keattisak Sripimanwat, National Electronics and Computer Technology Center	
FPM2-5-1	**An Implementation of a SCADA System based on Embedded TCP/IP Protocol Stack and**	**959**
3:20 PM	**Internet** Nguyen Ich Vinh, Watit Benjapolakul, Krisada Visavateeranon *Department of Electrical Engineering, Faculty of Engineering, Chulalongkorn University, Bangkok, Thailand*	
FPM2-5-2	**Channel Modeling and Simulated for Broadband Satellite**	**963**
3:40 PM	Ekavit Nukfron[1], Narong Hemmakorn[2], Suviporn Sitichepak[2] *[1]School of Graduate King Mongkut's Institute of Technology Ladkrabang , Bangkok, Thailand* *[2]Departments of Telecommunication Engineering, Faculty of Engineering, King Mongkut's Institute of Technology Ladkrabang, Bangkok, Thailand*	

FPM2-5-3	**Ionospheric Variability of foF2 at Low Latitude Station, Thailand**	**967**
4:00 PM	N. Wichaipanich, R. Attaviriyasuwon, N. Hemmakorn, P. Supnithi *Research Center for Communications and Information Technology (ReCCIT),* *Department of Information Engineering, Faculty of Engineering,* *King Mongkut's Institute of Technology Ladkrabang, Bangkok, Thailand*	
FPM2-5-4	**Improvement of Aggressive Fairness in RPR Based Dynamic Fair Rate Estimation**	**971**
4:20 PM	Thawatchai Rungsubsin, Siriwhaddhanah Pongpadpinit *Department of Telecommunications Science, Faculty of Science and Technology,* *Assumption University, Bangkok, Thailand*	
FPM2-5-5	**Investigation of Rain Attenuation on Vertical and Horizontal Polarizations of Thaicom**	**975**
4:40 PM	**Satellites** Pongputhai Udomareyasap, Donekeo Lakanchanh, Narong Hemmakorn, Nipha Leelaruji *Research Center for Communications and Information Technology (ReCCIT),* *Department of Information Engineering, Faculty of Engineering,* *King Mongkut's Institute of Technology Ladkrabang, Bangkok, Thailand*	

10:50 AM - 12:10 AM **Session TAM1-9** **Thursday,10 May 2007**

Image Technology

Chairperson : Akira Taguchi, Masashi Institute of Technology

TAM1-9-1	**Multiple Correspondences in Stereoscopy Using Frequency-Encoding Light Point**	**979**
10:50 AM	P. Tosranon [1,2], S. Bunluechokchai[2], C. Pintavirooj[1], M. Sangworasil[1] [1]*Research Center for Communications and Information Technology (ReCCIT),* *King Mongkut's Institute of Technology Ladkrabang, Thailand* [2]*Department of Industrial Physics and Medical Instrumentation,* *King Mongkut's Institute of Technology North Bangkok, Bangkok, Thailand*	
TAM1-9-2	**Automatic Alignment of White Blood Cell Using Principal Axis: The Improvement For**	**983**
11:10 AM	**Classification** P.Yampri[1], C.Pintavirooj[1], M. Sangworasil[1], P.Lertprasert[1], T.Rerksngaem[2] [1]*Research Center for Communication and Information Technology (ReCCIT)* *King Mongkut's Institute of Technology Ladkrabang, Bangkok, Thailand* [2]*Faculty of Allied Health, Thammasart University, Prathumthani, Thailand*	
TAM1-9-3	**Load Balancing Algorithm for Multipoint Video Conferencing Control Unit**	**987**
11:30 AM	Jirayu Charoenviriyaphap, Surin Kittitornkun *Department of Computer Engineering, Faculty of Engineering,* *King Mongkut's Institute of Technology Ladkrabang, Bangkok, Thailand*	
TAM1-9-4	**Continuous Thai Sign Language Recognition using HMM with Transition Models**	**991**
11:50 AM	Arunee Jaruwanawat, Nopporn Chotikakamthorn *Research Center for Communications and Information Technology,* *King Mongkut's Institute of Technology Ladkrabang, Bangkok, Thailand*	

1:00 PM - 3:00 PM **Session TPM1-7** **Thursday,10 May 2007**

Image Processing 1

Chairperson : Rachada Kangkachandra, Thammasat University

TPM1-7-1 **Shape-Based Object Segmentation by 2-Stage Level Set Method** **995**
1:00 PM Sarawut Tae-O-Sot[1], Supatana Auethavekiat[2], Somchai Jitapunkul[3]
[1]Department of Electrical Engineering, Naresuan University Phayao Campus, Phayao, Thailand
[2]National Electronics and Computer Technology Center, Patumthanee, Thailand
[3]Center of Excellence in Telecommunication Technology,
Department of Electrical Engineering, Chulalongkorn University, Bangkok, Thailand

TPM1-7-2 **Digital Image Compression using VPIC Algorithm in Wavelet Domain** **999**
1:20 PM K. Tongtar, N. Moongflangklang, F. Cheevasuvit
Department of Instrumentation Engineering, Faculty of Electrical Engineering,
King Mongkut's Institute of Technology Ladkrabang, Bangkok Thailand

TPM1-7-3 **Thai Banknote Verification and Recognition** **1003**
1:40 PM Narin Jeeranantasin, Pranchalee Rattanasakronchai
Department of Control System and Instrumentation Engineering,
King Mongkut's University of Technology Thonburi, Bangkok, Thailand

TPM1-7-4 **Locating and Reading Barcodes from Images Captured by Camera of Mobile Phone** **1007**
2:00 PM Sakda Suwanchatree, Pranchalee Rattanasakornchai
Control System and Instrumentation Engineering,
King Mongkut's University of Technology Thonburi, Bangkok, Thailand

TPM1-7-5 **Decision Combination of Multiple Classifier Systems for Multiresolution Face** **1011**
2:20 PM **Recognition**
P. Sermwuthisarn[1], W. Asdornwised[1], S. Jitapunkul[1], S. Marukatat[2]
[1]Department of Electrical Engineering, Chulalongkorn University, Bangkok, Thailand
[2]National Electronics and Computer Technology Center (NECTEC), Pathumthani, Thailand

TPM1-7-6 **On-Line Character Recognition for Khmer Numeral based on DP matching** **1015**
2:40 PM **of Barycenter Trajectory**
P. Thumwarin[1], S. Khem[1], K. Janchitrapongvej[1], T.Matsuura[2]
[1]Faculty of Engineering and Research Center for Communications and Information Technology ,
King Mongkut's Institute of Technology Ladkrabang, Bangkok, Thailand
[2]Faculty of Information Technology and Electronics, Tokai University, Kanagawa, Japan

3:20 PM - 5:00 PM **Session TPM2-3** **Thursday,10 May 2007**

Pattern Recognition and Others

Chairperson : Kosin Chamnongthai, King Mongkut's University of Technology Thonburi

TPM2-3-1 **The Use of Context-free Grammars in Isolated Word Recognition** **1019**
3:20 PM C. Chirathamjaree
Edith Cowan University, Australia

TPM2-3-2 **3:40 PM**	**Curvature Tree for Isolated Unconstrained Lao Handwritten Character Recognition** Khampheth Bounnady[1], Boontee Kruatrachue[1], Takenobu Matsuura[2] *[1]Computer Engineering Department, Faculty of Engineering,* *King Mongkut's Institute of Technology Ladkrabang, Bangkok, Thailand* *[2]Communications Engineering Department, Faculty of Information Technology and Electronics,* *Tokai University, Japan*	**1022**
TPM2-3-3 **4:00 PM**	**Combination of Self-Organizing Map and Fuzzy C-Means Algorithms for Project Performance Segmentation in Agricultural Technology Transfer and Service Centers** Sasithorn Mongkolsripattana, Anongnart Srivihok *Department of Computer Science, Faculty of Science, Kasetsart University, Bangkok, Thailand*	**1026**
TPM2-3-4 **4:20 PM**	**Automatic Floor-Mopping Robot** Wiruch Kongsin, Poj Tangamchit *Department of Control System and Instrument Engineering,* *King Mongkut's University of Technology Thonburi, Bangkok, Thailand*	**1030**
TPM2-3-5 **4:40 PM**	**Sansarn Offline: A Search Engine Tool for Managing, Archiving and Retrieving Offline Web Contents** Choochart Haruechaiyasak, Chatchawal Sangkeettrakarn *Human Language Technology (HLT) Laboratory,* *National Electronics and Computer Technology Center (NECTEC), Pathumthani, Thailand*	**1034**

3:20 PM - 5:00 PM **Session TPM2-7** **Thursday,10 May 2007**

Speech And Acoustic Technology

Chairperson : Rachada Kangkachandra, Thammasat University

TPM2-7-1 **3:20 PM**	**Combined Simulated Data Adaptation and Piecewise Linear Transformation for Robust speech recognition** Nattanun Thatphithakkul[1], Boontee Kruatrachue[1], Chai Wutiwiwatchai[2], Sanparith Marukatat[2,] Vataya Boonpiam[2] *[1]King Mongkut's Institute of Technology Ladkrabang, Bangkok , Thailand* *[2]National Electronics and Computer Technology Center, Pathumthani, Thailand*	**1038**
TPM2-7-2 **3:40 PM**	**Prosody-based Naturalness Improvement in Thai Unit-selection Speech Synthesis** A. Rugchatjaroen, A. Thangthai, S. Saychum, N. Thatphithakkul, C. Wutiwiwatchai *Human Language Technology Laboratory,* *National Electronics and Computer Technology Center (NECTEC), Pathumthani, Thailand*	**1042**
TPM2-7-3 **4:00 PM**	**Variable Momentum LMS Algorithm for Adaptive Howling Suppression in Audio Amplifier Systems** W. Loetwassana[1], R. Punchalard[2], J. Koseeyaporn[1], P. Wardkein[1] *[1]Department of Telecommunication Engineering, Faculty of Engineering,* *King Mongkut's Institute of Technology Ladkrabang, Bangkok, Thailand* *[2]Department of Telecommunication Engineering, Faculty of Engineering,* *Mahanakorn University of Technology, Bangkok, Thailand*	**1046**

TPM2-7-4	**The Improvement a New Method for a Front-End of Military Vehicles Sound**	**1050**
4:20 PM	**Recognition Using EHMM**	
	Yingyot Sa-nguanpuag[1], Panuthat Boonpramuk[2]	
	[1]Graduate school of Electrical engineering,	
	King Mongkut's University of Technology Thonburi, Bangkok, Thailand	
	[2] Instrumentation and Control System Engineering Department,	
	King Mongkut's University of Technology Thonburi, Bangkok, Thailand	
TPM2-7-5	**Precise Phone Boundary Detection using Selective Context-dependent Acoustic**	**1054**
4:40 PM	**Refinement**	
	Sirinoot Boonsuk, Proadpran Punyabukkana, Atiwong Suchato	
	Department of Computer Engineering,	
	Faculty of Engineering, Chulalongkorn University, Bangkok, Thailand	

8:30 AM - 9:50 AM	**Session FAM1-6**	**Friday,11 May 2007**
	Digital Signal Processing 1	
	Chairperson : Tanee Demeechai, Mahanakorn University of Technology	
FAM1-6-1	**Novel Precision Current-mode Full-wave Rectifier and Class B Push-Pull Current**	**1058**
8:30 AM	**Amplifier Using BiCMOS Current-controlled Current Conveyors**	
	Winai Jaikla[1], Montree Siripruchyanun[2]	
	[1]Electric and Electronic Program, Faculty of Industrial Technology,	
	Suan Sunandha Rajabhat University, Bangkok, Thailand	
	[2]Department of Teacher Training in Electrical Engineering, Faculty of Technical Education,	
	King Mongkut's Institute of Technology North Bangkok, Bangkok, Thailand	
FAM1-6-2	**Optical Diffraction-Based Object Dimensions Measurement in Reflection and**	**1062**
8:50 AM	**Transmission Modes**	
	Sarun Sumriddetchkajorn, Kosom Chaitavon	
	Photonics Technology Laboratory,	
	National Electronics and Computer Technology Center, Pathumthani, Thailand	
FAM1-6-3	**CCCDTAs-based Versatile Quadrature Oscillator and Universal Biquad Filter**	**1065**
9:10 AM	Winai Jaikla[1], Montree Siripruchyanun[2]	
	[1]Electric and Electronic Program, Faculty of Industrial Technology,	
	Suan Sunandha Rajabhat University, Bangkok, Thailand	
	[2]Department of Teacher Training in Electrical Engineering, Faculty of Technical Education,	
	King Mongkut's Institute of Technology North Bangkok, Bangkok, Thailand	
FAM1-6-4	**A Study of Optical Phase Retardation and Absorption Measurement by using a Fiber**	**1069**
9:30 AM	**Loop Mirror Architecture**	
	Kanitha Katanyukunanon[1], Sarun Sumriddetchkajorn[2], Toemsak Srikhirin[1]	
	[1]Department of Physics, Faculty of Science, Mahidol University, Bangkok, Thailand	
	[2]Photonics Technology Laboratory,	
	National Electronics and Computer Technology Center(NECTEC),	
	National Science and Technology Development Agency (NSTDA), Pathumthani, Thailand	

10:30 AM - 12:10 AM **Session FAM2-6** **Friday,11 May 2007**

Image Processing 2

Chairperson : Manas Sangworasil, King Mongkut's Institute of Technology Ladkrabang

FAM2-6-1 **Ultrasonic Reflection Tomography using Frequency Centroid-Shift Method** **1073**
10:30 AM
T. Onemanisone[1], C. Pintavi rooj[1], K. Wong-ek [2], S. Sangworasilp[1]
[1]Department of Electronics, Faculty of Engineering,
King Mongkut's Institute of Technology Ladkrabang, Bangkok, Thailand
[2]Department of Medical Technology, Faculty of Allied Health Science,
Thammasat University, Pathumthani, Thailand

FAM2-6-2 **Non-uniform Color Quantization for Content-based Image Retrieval** **1077**
10:50 AM
R. Sombutkaew, O. Chitsobhuk
Department of Computer Engineering, Faculty of Engineering,
King Mongkut's Institute of Technology Ladkrabang, Bangkok, Thailand

FAM2-6-3 **Image Coding Using Vector Quantization Based on Low-Frequency Component to** **1081**
11:10 AM **Determine Block Size**
Tanasak Phanprasit[1], Manas Sangworasil[1,2], Kosin Chamnongthai[3]
[1]Research Center for Communication and Information Technology (ReCCIT),
King Mongkut's Institute of Technology Ladkrabang, Bangkok, Thailand
[2]Computer Research and Service Center,
King Mongkut Institute of Technology Ladkrabang, Bangkok, Thailand
[3]Department of Electronic and Telecommunication Engineering,
King Mongkut's University of Technology Thonburi, Bangkok, Thailand

FAM2-6-4 **Image Coding Using Vector Quantization Based on System Error Compensate** **1085**
11:30 AM
Tanasak Phanprasit[1], Manas Sangworasil[1,2], Kosin Chamnonthai[3]
[1]Department of Electronics, Research Center for Communications and Information Technology,
King Mongkut Institute of Technology Ladkrabang, Bangkok, Thailand
[2]Computer Research and Service Center,
King Mongkut Institute of Technology Ladkrabang, Bangkok, Thailand
[3]Department of Electronic and Telecommunication Engineering,
King Mongkut's University of Technology Thonburi, Bangkok, Thailand

FAM2-6-5 **Direct Manipulation of 3D Curves with Pseudo- Physical Simulation Model** **1089**
11:50 AM
Pathawut Pichaichanlert, Nopporn Chotikakamthorn
Research Center for Communications and Information Technology,
King Mongkut's Institute of Technology Ladkrabang, Bangkok, Thailand

10:30 AM - 12:10 AM **Session FAM2-8** **Friday,11 May 2007**

Digital Signal Processing 3

Chairperson : K.R. Rao, The University of Texas at Arlington

FAM2-8-1 **Sequence Mirroring Properties of Orthogonal Transforms Having Even** **1094**
10:30 AM **and Odd Symmetric Vectors**
Do Nyeon Kim, K. R. Rao
Department of Electrical Engineering, University of Texas at Arlington, USA

FAM2-8-2	**Multi-Resolution Belief Propagation for StereoVision**	**1098**
10:50 AM	Preeyakorn Tipwai, Suthep Madarasmi *Department of Computer Engineering,* *King Mongkut's University of Technology Thonburi, Bangkok, Thailand*	
FAM2-8-3	**Estimating Radar Cross Section by Anisotropic Diffusion**	**1102**
11:10 AM	Sathit Intajag *King Mongkut's Institute of Technology Ladkrabang, Bangkok, Thailand*	
FAM2-8-4	**Fitting Model on BOD Response Curve**	**1106**
11:30 AM	Ekkawat Choona[1], Pakorn Kaewtrakulpong[1], Werasak Surareungchai[2], Pornpimol Sritongkam[2] *[1]Department of Instrumentation and Control System Engineering ,* *King Mongkut's University of Technology Thonburi, Bangkok, Thailand* *[2]Faculty of Engineering,Pilot Plant Development and Training Institute ,* *King Mongkut's University of Technology Thonburi, Bangkok, Thailand*	
FAM2-8-5	**Design of Adaptive Chrominance Delay Equalizer using Linear-Phase FIR Digital Filter**	**1110**
11:50 AM	V. Chutchavong, C. Benjangkaprasert, O. Sangaroon, K. Janchitrapongvej *Faculty of Engineering,* *King Mongkut's Institute of Technology Ladkrabang, Bangkok, Thailand*	

3:20 PM - 4:40 PM	**Session FPM2-6** **Image Processing 3** Chairperson : Vutipong Areekul, Kasetsart University	**Friday,11 May 2007**
FPM2-6-1	**Quantum Dot Molecule Chains and Their Polarization Photoluminescence**	**1114**
3:20 PM	N. Budsayaplakorn, S. Thainoi, S. Panyakeow *Department of Electrical Engineering, Faculty of Engineering,* *Chulalongkorn University, Bangkok, Thailand*	
FPM2-6-2	**3D Deformable Mesh Aided Dentistry**	**1117**
3:40 PM	C. Sinthanayothin, W. Bholsithi, W. Tharanon *Advanced Dental Technology Center (ADTEC),* *National Science and Technology Development Agency (NSTDA), PathumThani, Thailand*	
FPM2-6-3	**A Localization Method for Thailand License Plates**	**1121**
4:00 PM	Therdsak Chanfuangfoo[1], Pakorn Kaewtrakulpong[1], Supakorn Siddhichai[2] *[1]Department of Control System and Instrumentation Engineering ,* *King Mongkut's University of Technology Thonburi, Bangkok, Thailand,* *[2]National Electronics and Computer Technology Center (NECTEC), Pathumthani, Thailand*	
FPM2-6-4	**A Study of Normalized Cross Correlation Pattern Matching Algorithm in Thermal Imagery**	**1125**
4:20 PM	Sarun Sumriddetchkajorn, Armote Somboonkaew *National Electronics and Computer Technology Center, Pathumthani, Thailand*	

10:50 AM - 12:10 AM | **Session TAM1-2** | **Thursday,10 May 2007**

Processors

Chairperson : Prabhas Chongsatitwattana, Chulalongkorn University

TAM1-2-1 **Hardware Cryptography-Embedded Multimedia Mobile Processor** **1128**

10:50 AM

Masa-aki Fukase[1], Hiroki Takeda[1], Tomoaki Sato[2]

[1]*Faculty of Science and Technology, Hirosaki University, Japan*

[2]*Computer and Network Systems Center, Hirosaki University, Japan*

TAM1-2-2 **HDL Design and Verification of Digital Signal Processor for 2.4 GHz ZigBee Radio Receiver** **1132**

11:10 AM

T. Demeechai

Department of Telecommunication Engineering,

Mahanakorn University of Technology, Bangkok, Thailand

TAM1-2-3 **An Embedded Processor with Instruction Packing** **1135**

11:30 AM

C. Satayavibul, P. Chongstitvatana

Department of Computer Engineering,

Chulalongkorn University, Bangkok, Thailand

TAM1-2-4 **The AES Encryption Circuit on a Reconfigurable Hardware** **1139**

11:50 AM

J. Sripornprasert, P. Chongstitvatana

Department of Computer Engineering,

Chulalongkorn University, Bangkok, Thailand

1:00 PM - 2:40 PM | **Session TPM1-9** | **Thursday,10 May 2007**

Software Engineering and Applications

Chairperson : Prabhas Chongsatitwattana, Chulalongkorn University

TPM1-9-1 **Hardware Model Checking and Computational Temporal Logic(CTL)** **1143**

1:00 PM

Hamid Shojaei[1], Majid Nabi[2], Zainalabedin Navabi[2], Mohammad Reza Kakoee[1]

[1]*Islamic Azad University, Damavand Branch*

[2]*CAD Research Group, Faculty of Engineering, University of Tehran , Tehran, Iran*

TPM1-9-2 **Undeniable Fair Electronic Auction** **1147**

1:20 PM

Yongyuth Permpoontanalarp, Montri Apiromvorakarn

Department of Computer Engineering, Faculty of Engineering,

King Mongkut's University of Technology Thonburi, Bangkok, Thailand

TPM1-9-3 **A Cost Model for Bitmap Index Partition Techniques** **1151**

1:40 PM

Manlika Honghirun, Songrit Maneewongvatana

Department of Computer Engineering,

King Mongkut's University of Technology Thonburi, Bangkok, Thailaind

TPM1-9-4 **Towards Evolvable Safety Arguments** **1155**

2:00 PM

Paul Mason, Chadchai Mattayom

Shinawatra University, Bangkok, Thailand

TPM1-9-5	**Extending Cross-Tool Traceability to Source Code**	**1159**
2:20 PM	P. A. J. Mason *Shinawatra University, Bangkok, Thailand*	

1:00 PM - 3:00 PM	**Session TPM1-10** **Network Systems**	**Thursday,10 May 2007**
	Chairperson : Phongsak Keeratiwintakorn, King Mongkut's Institute of Technology North Bangkok	
TPM1-10-1	**Cellular Wireless Network Design with Genetic Algorithm**	**1163**
1:00 PM	Pakorn Leesutthipornchai[1], Naruemon Wattanapongsakorn[1], Chalermpol Charnsripinyo[2] [1]*Department of Computer Engineering,* *King Mongkut's University of Technology Thonburi, Bangkok, Thailand* [2]*National Electronics and Computer Technology Center, Pathumthani, Thailand*	
TPM1-10-2	**Performance Analysis of IEEE 802.11g Access Point under Heavy-Loaded Condition**	**1167**
1:20 PM	Roungsan Chaisricharoen, Thitiporn Pramoun *School of Information Technology, Mae Fah Luang University, Chiang Rai, Thailand*	
TPM1-10-3	**Time-Optimal Graph Algorithms for Finding Adjacent and Non-Adjacent**	**1171**
1:40 PM	**Nodes on a Completely Overlapping Network** Rasika Winit[1], Sanpawat Kantabutra[2], Saowaluk Rattanaudomsawat[3] [1]*Schools of Physics and Biological Earth and Environmental Science,* *Faculty of Science, the University of New South Wales, Sydney, Australia* [2]*The Theory of Computation Group, Computer Science Department,* *Chiang Mai University, Thailand* [3]*School of Information Technology, Mae Fah Luang University, Chiang Rai, Thailand*	
TPM1-10-4	**On the Effects of VLAN in WLAN-based Positioning System**	**1174**
2:00 PM	Chalermchai Khauphung[1], Phongsak Keeratiwintakorn[1], Kamol Kaemarungsi[2] [1]*Department of Electrical Engineering,* *King Mongkut's Institute of Technology North Bangkok, Bangkok, Thailand* [2]*National Electronics and Computer Technology Center (NECTEC), Pathumthanee, Thailand*	
TPM1-10-5	**On the Effect of Roadside Stations in Routing for Inter-Vehicle Communications**	**1178**
2:20 PM	Phitsanu Eamsomboon[1], Phongsak Keeratiwintakorn[1], Chaichana Mitrpant[2] [1]*Department of Electrical Engineering,* *King Mongkut's Institute of Technology North Bangkok, Bangkok, Thailand* [2]*National Electronics and Computer Technology Center (NECTEC), Pathumthanee, Thailand*	
TPM1-10-6	**The Improvement of TCP Performance in Heterogeneous Networks**	**1182**
2:40 PM	K. Kuprasert, P. Oothongsap *Department of Electrical Engineering, Faculty of Engineering,* *King Mongkut's Institute of Technology North Bangkok, Bangkok, Thailand*	

3:20 PM - 5:00 PM **Session TPM2-9** **Thursday,10 May 2007**

Simulation and Modelling

Chairperson : Nachol Chaiyaratana, King Mongkut's Institute of Technology North Bangkok

TPM2-9-1 **Early Warning of Internet Worms by ICMP Scan Data Visualization** **1186**
3:20 PM
Pitichai Pitimaneeyakul, Saroj K. Biswas
Department of Electrical and Computer Engineering, Temple University, Philadelphia

TPM2-9-2 **A Cost-Efficient Algorithm for Arbitrary CRCW PRAM Simulation** **1190**
3:40 PM
Martti Forsell
Platform Architectures Team,
VTT Technical Research Center of Finland, Oulu, Finland

TPM2-9-3 **Development of Low-cost Parachute Training Simulaion System** **1194**
4:00 PM
Sombat Hathairattananon, Thavida Maneewarn
Institute of Field Robotics (FIBO),
King Mongkut's University of Technology Thonburi, Bangkok, Thailand

TPM2-9-4 **Separation of Concerns in Modeling System Software for Automate Code Generation** **1198**
4:20 PM
Paniti Netinant
Computer Sceince Departmnet, Bangkok University, Bangkok, Thailand

TPM2-9-5 **Multidimensional Binary Clustering Tree for Surface Simplification of Point-Sampled** **1202**
4:40 PM **Surface**
Thanet Suphan, Chakrit Watcharopas
Department of Computer Science, Faculty of Science, Kasetsart University, Bangkok, Thailand

8:30 AM - 10:10 AM **Session FAM1-8** **Friday,11 May 2007**

Information Technology 1

Chairperson : Tong Srikhacha, The Telephone Organization of Thailand

FAM1-8-1 **Data Prediction by Support Vector Regression with a Decomposition Method** **1205**
8:30 AM
Phayung Meesad[1], Tong Srikhacha[2]
[1]*Department of Teacher Training in Electrical Engineering, Faculty of Technical Education*
[2]*Department of Information Technology, Faculty of Information Technology,*
King Mongkut's Institute of Technology North Bangkok, Bangkok, Thailand

FAM1-8-2 **Knowledge Management System with Root Cause Analysis for IT Service Desk in** **1209**
8:50 AM **Banking Business**
Padej Phomasakha Na Sakolnakorn[1], Phayung Meesad[2]
[1]*Faculty of Information Technology,*
King Mongkut's Institute of Technology North Bangkok, Bangkok, Thailand
[2]*Faculty of Technical Education,*
King Mongkut's Institute of Technology North Bangkok, Bangkok, Thailand

FAM1-8-3 **Web Metadata Design for Web Content Management** **1213**
9:10 AM
Natthaphon Sueb-Am, Mayuree Lertwatechakul
Department of Information Engineering, Faculty of Engineering,
King Mongkut's Institute of Technology Ladkrabang, Bangkok, Thailand

FAM1-8-4	**Towards Intelligent and Adaptive Digital Library Services: Associating Contents with**	**1217**
9:30 AM	**User Profile and Usage Pattern in Digital Libraries**	
	Yenruedee Chanwirawong, Md Maruf Hasan	
	School of Technology, Shinawatra University, Bangkok, Thailand	
FAM1-8-5	**Improve XML Web Services' Performance By Compressing XML Schema tag**	**1221**
9:50 AM	Tanakorn Wichaiwong, Chuleerat Jaruskulchai	
	Department Of Computer Science, Faculty of Science, Kasetsart University, Bangkok, Thailand	
10:30 AM - 11:50 AM	**Session FAM2-9**	**Friday,11 May 2007**
	Medical Engineering and Applications	
	Chairperson : Nachol Chaiyaratana, King Mongkut's Institute of Technology North Bangkok	
FAM2-9-1	**An Incremental Learning Algorithm Based-On Mahalanobis Distance for Breast**	**1225**

Abstract-The design of microstrip filter using radial line stub as reactive elements is investigated. Fractalization of this geometry has been proposed. The frequency response characteristics of specified microstrip radial-line stub filter is compared to the fractal microstrip radial-line stub.

1. Introduction

In microwave applications, it is often required to select or reject signals over specified frequency bands is often required. Filters accomplish this task. Depending on the application, low-pass, high-pass, band-pass or band-reject filtering may be provided [1], [2]. Filters employing open-circuited stubs are the simplest to design [3]. The stubs used are mostly straight and uniformly distributed. However, filters, which use a combination of both uniform and non-uniform characteristic impedance lines, can also be designed.

The non-uniform, characteristic impedance line considered here is a radial line. A low pass Butter- worth filter using radial line stubs is investigated. Fractals in this radial-line low-pass conventional filter have been done. The performance of the conventional and the fractalized geometries have been analyzed using the commercially available IE3D simulator [4]. The transmission line structures are assumed to be planar so that the filters may be realized in microstrip line.

2. Filter Design and Synthesis

A .Radial-line Elements

The standard geometry of a radial-line stub, as defined by Atwater [5], is shown in Fig. 1. The radial-line stub geometry is modified to an isosceles triangle, as shown in Fig. 2.

With the use of radial line stubs, the input impedance Z_{in} of the stubs is modified. For the low pass applications, the simplified expression for Z_{in} is [6]

$$Z_{in} = -jZ_0(l)\cot\left[\frac{\beta}{2}\left\{\frac{l_0^2}{l_0 - l} - (l_0 - l)\right\}\right] \quad (1)$$

$$= -jZ_{max}\cot\left[\frac{\beta l}{2}\left(1 + \frac{Z_{max}}{Z_{min}}\right)\right] \quad (2)$$

where,

$Z_{max} = Z_o(l)$ *and* $Z_{min} = Z_o(0)$

Thus equation (1) is the design equation for the radial-line stubs. It is to introduce the radial–line stub as a reactive element available for use in filter design. The proposed design technique is to use radial-line stubs in place of shunt capacitors and short sections of high impedance uniform transmission line for the series inductors. Using (1), the filter design equations for elements are

Inductors:

$$X_L = Z_o g_m = Z_L \sin(\theta_m) \quad (3)$$

Internal Capacitors (stubs):

$$B_c = \frac{g_m}{Z_o} = \frac{1}{Z_L}\tan(\theta_{m-1}/2) + \frac{1}{Z_{max}}\tan\left[\frac{\theta_m}{2}\left(1 + \frac{Z_{max}}{Z_{min}}\right)\right] + \frac{1}{Z_L}\tan(\theta_{m+1}/2) \quad (4)$$

End Capacitors (stubs):

$$B_C = \frac{1}{Z_L}\tan(\theta_{m\pm1}/2) + \frac{1}{Z_{max}}\tan\left[\frac{\theta_m}{2}\left(1 + \frac{Z_{max}}{Z_{min}}\right)\right] \quad (5)$$

where, Z_L is the characteristics impedance of the inductive line section, Z_O is the filter impedance level, and the electrical length θ is given by

$$\theta_m = \frac{2\pi\sqrt{\varepsilon_{eff}}}{c} lf \quad (6)$$

In equation (6), f is the match frequency i.e. $f = fc$ for inductors and $f \approx fc/2$ for capacitors and

$$\varepsilon_{eff} \equiv \frac{\varepsilon_{eff}\big|_{z=0} + \varepsilon_{eff}\big|_{z=l}}{2}$$

ε_{eff} is the effective relative permittivity. It is the average value of the wide and narrow ends of the stub.

To obtain the electrical length of the inductive line sections and the radial stubs, values for Z_L, Z_{max} and Z_{min} must be chosen.

B Low pass filter synthesis

The attenuation characteristics for a maximally-flat low pass (also called Butterworth) filter, can be mathematically expressed as [2]

$$L_{Ar}(\omega_1) = 10 \log_{10}\left[1 + \varepsilon\left(\omega/\omega_1\right)^{2n}\right] \text{dB} \quad (7)$$

The frequency ω_1 where the attenuation is L_{Ar} is defined as the pass band edge and

$$\varepsilon = |\text{antilog}_{10}(L_{Ar}/10)|-1 \quad (8)$$

Figure 1 shows LC Ladder Network Realization maximally flat low pass prototype filter [2], having resistor terminations at both the ends. The element values may be computed as [3]

$$g_o = 1 \quad (9)$$

$$g_k = 2\sin[(2k-1)\Pi/2n] \quad (10)$$

where $k = 1, 2, 3 \ldots n$

$$g_{n+1} = 1 \quad (12)$$

In this section simulation results for n = 5 equal ripple low pass filter will be presented, with passband ripple of 0.1dB.

A low pass microstrip filter using radial-Line stub, designed using the conventional technique [7, 8] for the following parameters,

Cut-off frequency, fc = 0.75 GHz, dielectric constant, εr = 4.7, substrate height, h = 1.6mm

Characteristics impedance, Z_0 = 50 Ω, Z_L= 100 Ω, Z_{max} = 50 Ω, Z_{min} = 20 Ω. Fig.5 shows the microstrip low pass filter using radial-line Stub.

3. Fractalised Low pass radial-line Filter

Fractalization has been done for this low pass radial-line filter, the rectangular shaped fractal of dimensions 4x3mm and 3x2 mm are etched out for the longer and shorter stubs respectively. The rectangular fractals and stubs are concentric. The length of rectangular fractals is oriented along the length of stubs.

4. Results and Discussion

Improvements in the frequency response of the filters have been obtained by fractalization. It is observed that the attenuation level of filter for the conventional geometry (Fig. 3) is 47 dB (Fig. 4) and for the fractalized geometry (Fig.5) is 50 dB (Fig. 6). The frequency response improves by 3 dB.

***Abstract*-This paper presents the effectiveness of reducing the center-to-center spacing of elements for broad beam microstrip reflectarray. For a given number of elements, it is shown that increased gain can be attainted for reduced center-to-center elements spacing with no significant change in array size.**

I. INTRODUCTION

A planar reflector or microstrip reflectarray is a printed low-profile antenna that consists of a grounded flat onto which a quasi-periodic array of resonant conducting element (patches or dipoles) is etched [1]-[4]. This operation is similar in concept to a parabolic reflector that naturally forms a planar phase front when a feed is placed at its focus. Each element phase can be adjusted to produce a required phase law over the antenna aperture.

In the wireless communication applications such as wireless local area network (WLAN) large-scale indoor base station [5], it is desirable the antenna which has wide beam to cover a broad area. The wide beam reflectarray for WLAN antenna is an alternative as shown in Fig. 1 [6]. A reflectarray configuration is attractive because it allows a single mechanical design to be used repeatedly for a wide variety of different coverage specifications. The only changes are required that the printed reflecting element dimensions can be changed for each design in order to generate the new shaped beam. Thus, many of the high recurring costs associated with shaped-reflector antennas can be eliminated with flat printed reflectarrays [7]. The flat geometry of a reflectarray also lends itself to easier placement and deployment on the WLAN large-scale indoor base station and also in terms of manufacture.

However, it is generally observed that when the antenna beam is enlarged, the antenna gain is reduced. In this paper, we have investigated the influence of the center-to-center spacing of reflectarray elements on the gain performance. To achieve such broad-beamwidth, phase of each array element in the reflectarray antenna is designed specifically to emulate the curvature of the backscatter function by using patches of different sizes. As the patch shape is not the aim of this work, it has been chosen to be simple to design regarding to the element position variation.

The first section, we will present the design approach as far as it concerns the center-to-center element spacing determination (Section II) and the reflection phase characteristic (Section III). In section IV, we apply this approach to calculate the radiation pattern of the proposed antenna. Finally, the conclusions are given in section V.

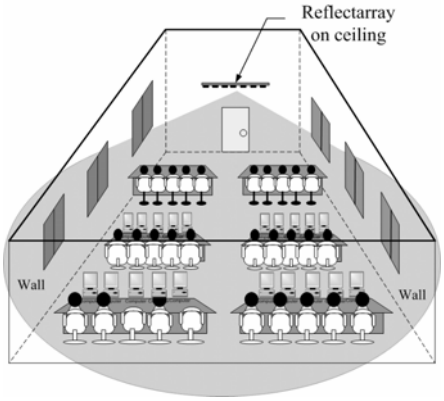

Figure 1. Reflectarray for WLAN large-scale indoor base station.

II. CENTER-TO-CENTER ELEMENT SPACING DETERMINATION

Fig. 2 shows the geometry of an infinite reflectarray element. As indicated, s is the center-to-center elements spacing in the x and y directions and L is the element size. To avoid the physical contacts among the adjacent elements, the grid spacing must be larger than the element size L,

$$\min\{s\} = L. \tag{1}$$

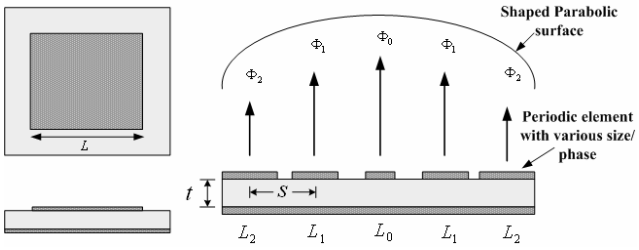

Figure 2. Geometry of an infinite reflectarray element.

The effective method for decreasing the grid spacing is to print the reflectarray elements on substrate, which reduces the size of reflectarray elements. In microstrip antenna, many

techniques have been reported to reduce the size of unit cell at a fixed operating frequency [8]. In general, reflectarray elements are half-wavelength structures at the 180° reflection phase and operated at a resonant frequency, which is given by

$$f_0 \cong \frac{c}{2L\sqrt{\varepsilon_r}}, \tag{2}$$

where c is the speed of light and ε_r is the relative permittivity of the grounded microwave substrate. From (2), it is found that the physical size of reflectarray elements will be decreased at a fixed operating frequency due to the use of the microwave substrate with a larger permittivity.

III. Reflection Phase Characteristic

A. Required Phase Delay

Fig. 3 illustrates the analysis model of a broad-beam microstrip reflectarray, which parameters used in this figure are described below:

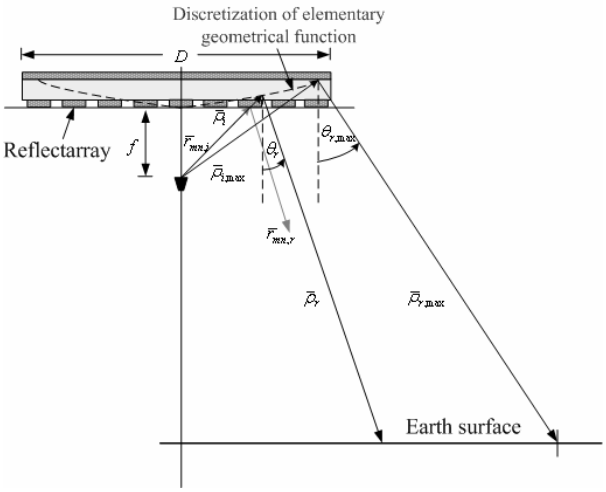

Figure 3. Analysis model of broad-beam microstrip reflectarray.

$\vec{r}_{mn,i}$ the vector from the feed to the *mn*-th reflectarray element, which can be obtained by using flat geometry;

$\vec{r}_{mn,r}$ the reflected vector from the reflectarray surface to far-field;

$\vec{\rho}_i$ the vector from the feed to the shaped reflector surface, which can be obtained by using curvature geometry;

$\vec{\rho}_r$ the reflected vector from the shaped reflector surface to far-field;

θ_i incidence angle;

θ_r reflection angle;

D diameter of the reflector;

f distance between the feed and the center of the reflectarray.

In general, the feed may be positioned at distance from the reflectarray. The path lengths from the feed to all reflectarray elements are all different, which lead to different phase delays. The required phase, which is induced on the array, has to compensate for phase delay $\Delta\Phi_{mn}$ between patch elements and surface of parabolic backscatter as expressed in (3).

$$\Delta\Phi_{mn} \text{ in degree} = \left[(1-N) k_0 \left(|\vec{\rho}_i| + \frac{z_b - f}{\sin\theta_r} - |\vec{r}_{mn,i}| \right) \right] \frac{180}{\pi}, \tag{3}$$

where (x_b, y_b, z_b) describes the coordinate of the parabolic backscatter function,

$$z_b = -\frac{x_b^2 + y_b^2}{4f} - f, \tag{4}$$

and N is integer. From (3) indicates that the compensating phase can be repeated every 360 degree and the portion that is an integer multiple of 360 degree can be deleted.

The required phase delays that related to the patch position are determined for shaping beam of reflectarray as shown in Fig. 4 with various center frequencies (f_0 = 10 GHz). These phases are duplicated the same radiating aperture as shape of parabolic backscatter. In the design, a standard X-band horn is functioned to be the primary feed and located at distance f = 25 cm. The cell elements are printed on a TACONIC substrate with thickness 0.762 mm and permittivity ε_r = 2.33 and 6.15. Because reduction of center-to-center element spacing changes the elements position, the phase delays are decreased.

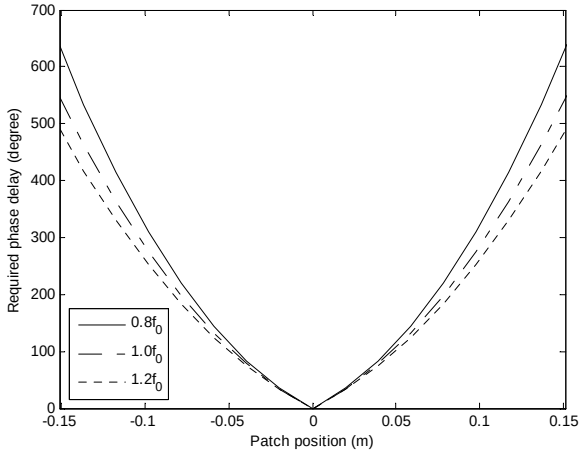

Figure 4. Calculated results of desired reflection phase properties.

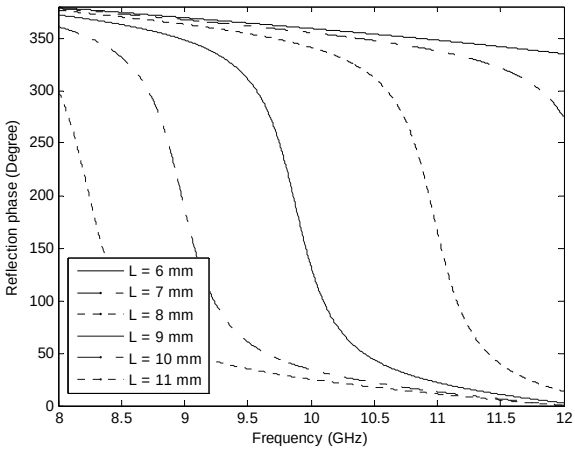
B. Element Characterization

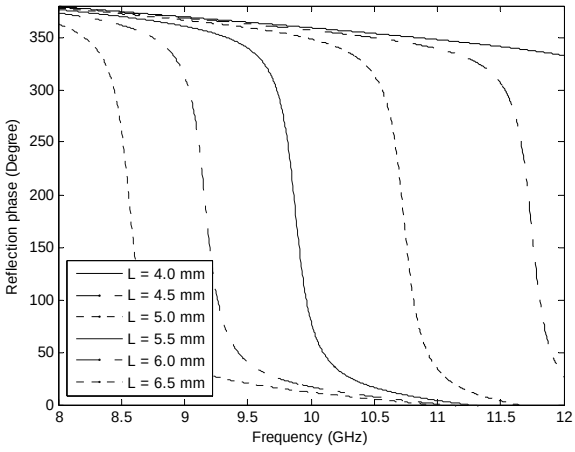
The most important and critical segment of the reflectarray design is its element characterization. To compensate for above phase delays, the elements must have corresponding phase advancements designed. Its phase change versus element change (patch size, etc.) must be calibrated correctly.

If the element design is not optimized, it will not scatter the signal from the feed effectively to form an efficient far-field beam. In this paper, the phase calibration technique is to use a full-wave method of moment and the infinite-array approach [6] to model the effect of the finite grounded dielectric substrate underlying the single radiator.

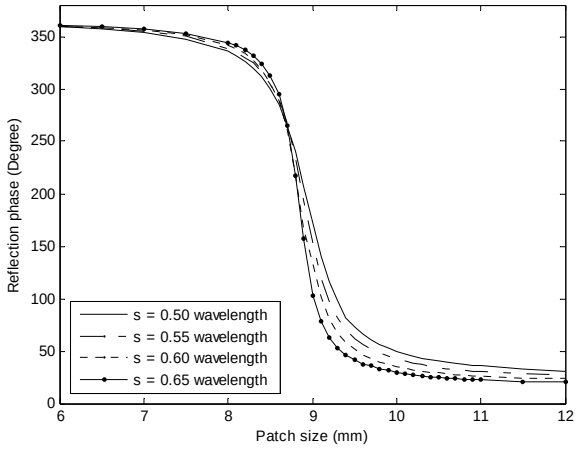
Fig. 5 shows simulated results of reflection phase of infinite array. The obtained results indicated that, if the element size L is excessively small, either the reflection phase cannot be made to cover the full required 0° to 360° phase range, or it changes excessively fast around the element resonance. This available phase shift rang is limited by the reflectarray antenna bandwidth (around 4%). In Fig. 5(c), the reductions of center-to-center spacing of reflectarray elements can reduce the slope of the phase response. For achieving reflectarray element with a reduced size at a fixed operating frequency, the use of a high-permittivity substrate is an effective method as shown in Fig. 5 (a)-(b).



(a)



(b)



(c)

Figure 5. Simulated results of element characterization: (a) at ε_r = 2.33, s = 0.6 λ_0, (b) at ε_r = 6.15, s = 0.6 λ_0, (c) at ε_r = 2.33, f_0 = 10 GHz.

IV. Calculation of Radiation Pattern

With the compensating phases of all elements known, the far-field radiation patterns can be calculated by the conventional array theory [9], where the radiations of all elements are summed together as follow. Considering a planar array consisting of $M \times N$ elements that are nonuniformly illuminated by a low-gain feed, the reradiated field from the patches in an arbitrary direction, $\hat{u}$, will be of the form,

$$E(\hat{u}) = \sum_{m=1}^{M}\sum_{n=1}^{N} F(\vec{r}_{mn}\cdot\hat{a}_z)\cdot A(\vec{r}_i\cdot\hat{u}_r)\cdot A(\hat{u}\cdot\hat{u}_r) \cdot \exp\left[-jk_0\left(|\vec{r}_{mn}|+\vec{r}_i\cdot\hat{u}\right)-j\Delta\Phi_{mn}\right], \tag{5}$$

where F is the feed pattern function, A is the reflectarray element pattern function, $\vec{r}_i$ is the vector from the centre of reflectarray to *mn*-th element. $\hat{u}_r$ is the reflected field pointing direction, and $\Delta\Phi_{mn}$ is the required compensating phase of the *mn*-th element calculated by (3).

Table I
Characteristics of Reflectarray.

Grid spacing (wavelength)	HPBW (degree)	Maximum relative power (dBi)
0.3	68	32.91
0.4	72	28.80
0.5	72	24.33
0.6	72	21.18
0.7	72	18.67

The radiated field from (5) provides the radiation characteristics, which are shown in Table I and Fig. 6 for various center-to-center spacing of reflectarray elements. The

prescribed field requirements have been satisfied by an appropriate choice of the radiating patches selected from the complex design curves obtained in the analysis stage. The steepness of the pattern edges and the angular positions of these edges confirm that the antenna efficiently illuminates the target area to be covered (±65°). Because of phase change versus element change, each center-to-center elements spacing provides different characteristics such as -3 dB beamwidth (HPBW) and relative power. The maximum relative power is increased due to reduction of grid spacing. Thus, the HPBW is decreased and followed by the same order as the relative power.

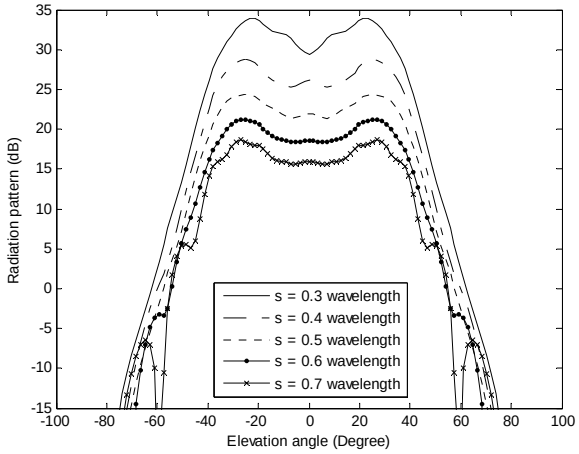


Figure 6: Radiation pattern of parabolic function.

V. CONCLUSIONS

A broad-beam microstrip reflectarray designed from square patch has been presented. The prescribed field requirements have been satisfied by an appropriate choice of the radiating patches array selected from the complex design curves obtained in the analysis stage. Simulation of this reflectarray demonstrates that reduction of center-to-center spacing of reflectarray elements can enhance bandwidth or reduce the slope of the reflection phase. In addition, the radiated power gain is improved with small significant change in HPBW.

***Abstract*—As a narrowband bandpass filter with wide stopband is needed for modern communication, a microstrip inductive-compensated coupling-fed ring bandpass filter with a SIR in loop resonator is proposed. Certain design approach for filter design procedure are derived based on ideal transmission line model. A designed narrowband bandpass filter operated at 2.4 GHz with a 5% bandwidth and wide stopband is presented. Simulated and experimental results of the design are performed to validate the technique proposed.**

***Index Terms* — Ring filter, narrowband, step-impedance resonator, inductive compensated, parallel-coupled lines**

I. INTRODUCTION

Microstrip ring resonators have found many applications in microwave communication circuits including oscillators [1], filters [2] ,tuned amplifiers [3], to name a few. For microwave bandpass filter design, ring resonator has been received much attention due to its simple design and narrow bandpass response [4]. However the multimode resonance inherent in ring resonator behavior partly contributes significant spurious magnitude in ring resonator based bandpass filter's response, which in turn degrades communication performance considerably.

Several techniques were proposed to alleviate the spurious response problem. Those proposed techniques have their own pros and cons. The first technique for spurious suppression, to the authors' knowledge, is applying a slow-wave coupler structure [5]. The technique though succeeds but lacks of a certain design rule. A simple technique such as cascading a low-pass filter [6] does not suit for practical applications as it increases passband loss, enlarges the filter bandwidth and, ultimately, reduces the signal-to-noise ratio.

Among the spurious suppression schemes, embedding a low-pass filter in a ring resonator [7] is in fact applicable. This is simply achieved by replacing a uniform-width transmission line in ring resonator loop with a step-impedance transmission line. This step-impedance ring resonator was proposed to apply with a step-width coupling-gap microstrip bandpass filter to provide narrow band response and large stop band [8]. Apart from its good performance, there is no certain design rule yet. Actually the concept of applying step-coupling feed to a microstrip ring filter design utilized in [8],[9] is originated from the works proposed for microstrip parallel-coupled filter [10] and hair-pin diplexer [11]. Non-uniform width coupling feed can effectively solve the spurious response in those circuits' passband by equalizing wave-mode velocities. We can therefore state that the spurious response in the filter is an outcome of unequal wave velocities in microstrip coupled lines. By this fact, techniques compensated wave-mode velocities are possible to apply for narrowband microstrip ring-resonator filter [12],[13].

So far, a simple yet effective technique to compensate wave velocities in parallel-coupled line is an inductive compensated coupled lines [14]. Consequently, in this paper, we first apply the technique combing with step-impedance ring loop to design a narrow band microstrip filter with wide stop band. Section 2 presents the background and the proposed technique's theories. Simulated and experiment results of the design 2.45 GHz microstrip filter of 5% bandwidth will be presented in Section 3. The paper is finally concluded in Section 4.

II. THEORY

A. Step Impedance Resonator (SIR)

Generally, step impedance resonators (SIR) which is a nonuniform transmission line resonator has been used in the filter design so as to reduce the circuits [15], to push the spurious passband to the higher frequency, and even to suppress the multiple spurious passbands [16]. The structures of SIR are shown in Fig. 1. Generally SIR structure is symmetrical and has two different characteristic admittances, Y_1 and Y_2, of corresponding electrical lengths θ_1 and θ_2. The admittance of the resonator from the open end, Y_i is given as [17]:-

$$Y_i = jY_2 \frac{2\left(K\tan\theta_1 + \tan\theta_2\right)\left(K - \tan\theta_1\tan\theta_2\right)}{K\left(1-\tan^2\theta_1\right)\left(1-\tan^2\theta_2\right) - 2\left(1+K^2\right)\tan\theta_1\tan\theta_2} \quad (1)$$

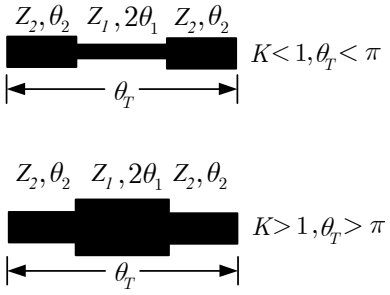

Fig. 1. Structure of the SIR [3].

where impedance ratio (K) is defined as Y_1/Y_2, and the total resonator electrical length $\theta_T = 2(\theta_1 + \theta_2)$. The anti-resonance condition can be obtained from the following condition:-

$$Y_i = 0 \tag{2}$$

Alternatively, the fundamental frequency can be express from the resonant condition as

$$K = \tan\theta_1 \tan\theta_2 \tag{3}$$

From (3), it is seen that the resonance condition not only depends on the lines length (θ_1 and θ_2) as in case of ordinary uniform impedance resonator (UIR), but also K. In addition, the previous work [17] indicated that zero transmission at other frequencies can be controlled by K. Here, we apply these properties of SIR to enhance the frequency response of bandpass filter based coupled feed ring resonator for obtaining sharp passband/stopband transition. The antiresonant condition shown in (2) will be applied at the desired zero frequencies which can be either located near passband or stopband. The solutions of K, θ_1, and θ_2 are fundamentally determined based on this fact.

B. Inductive Compensated Parallel-Coupled Lines

For microstrip parallel-coupled lines, the difference in phase velocities associated with the even- and odd-mode wave propagation contributes poor directivity in coupled lines, which in turn causes spurious response at filter stopband in bandpass filter. Obviously this is also unavoidable for microstrip ring filter with coupling feed. The technique used in this paper to eliminate the spurious response in the filter is to design coupling feed structure with high-directivity coupled lines. Normally microstrip parallel-coupled lines can not readily achieve directivity of better than 12 dB [18]. Nevertheless this can be simply surpassed with inductive compensated technique [14].

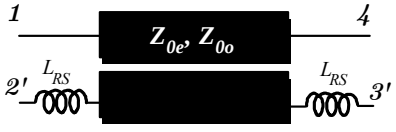

Fig. 2. Schematic of the inductive compensated parallel-coupled lines [19].

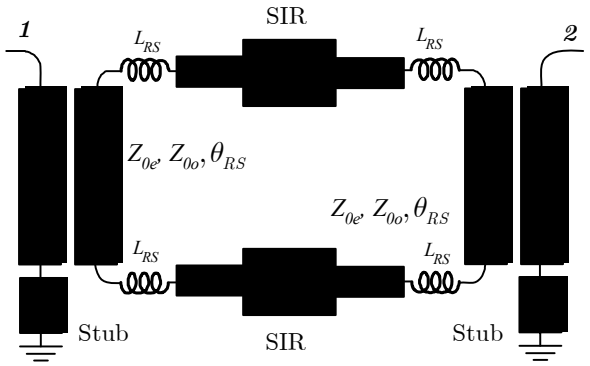

Fig. 3. Schematic of the proposed narrowband ring filter.

As shown in Fig. 2, the inductive compensated technique applied here is a modified one from their original structures [18]. Based on the four-port impedance parameters of the parallel-coupled lines model [19], the equation of the inductor (L_{RS}) for ring resonator designed at desired frequency (f_0) is presented [19]. This compensation inductors are related to the even- and odd-mode characteristic impedances ($Z_{0\mathrm{e}}$, $Z_{0\mathrm{o}}$) and effective even- and odd-mode permittivity ($\varepsilon_{\mathrm{effe}}$, $\varepsilon_{\mathrm{effo}}$).

After some mathematical manipulation, we obtain the optimum value of L_{RS} as shown:-

$$L_{RS} = \frac{1}{2\pi f_0}\mathrm{Im}\left\{\frac{\left(Z_o^2 + Z_{0o}^2\right)Z_C - 2Z_oZ_{0o}Z_{0e}\phi}{Z_oZ_C - Z_{0o}Z_{0e}\phi}\right\} \tag{4}$$

where $\phi = \cosh\theta_e - \cosh\theta_o$ and $Z_C = j\left(Z_{0o}\sin\theta_e - Z_{0e}\sin\theta_o\right)$ Equation (4) offers a closed-form expression to design the compensating inductances for achieving high directivity at f_0. The function of L_{RS} is to retard phase of the propagated signal.

It was clearly indicated that the zero-isolation frequency will be shifted to frequency which is lower than the original frequency [14]. This frequency can be simply shifted back to the desired frequency by modifying the electrical length of the compensated parallel-coupled line as shown:-

$$\theta_{RS} = \cot^{-1}\left\{\frac{4\pi f_0 L_{RS} - Z_{oo}\cot\theta_o}{2Z_{oe}}\right\} \tag{5}$$

In this paper, as mentioned above, an SIR and inductive compensated parallel-coupled lines are used in cooperated to form a new ring resonator bandpass filter. The proposed ring bandpass filter is shown in Fig. 3. Note that bandwidth tunable capability is succeeded with shorted stubs at coupling feeds. Sharp transition can be obtained by designing two zero frequencies (f_{Z1}, f_{Z2}) as shown in Fig. 4. Hence the proposed filter has many attractive characteristics which highly suits for wireless communication. These are sharp passband/stopband transition, wide stopband, tunable capability, and simple design and implementation.

The design procedure is very simple. The two zero frequencies are determined by solving the design equations of SIR where the compensated inductor and length of coupling feed are calculated from (5). Finally, if symmetry is passband response is needed, the short stub dimensions would be synthesized from the compensated inductor.

III. Design And Experimental Results

The technique validity is proven with a design of narrow bandpass filter operated at 2.45 GHz. The filter has a percentage bandwidth of 5. Sharp attenuation at both passband transitions are required. This is achieved with locating f_{Z1} and f_{Z2} at 1.9 and 2.6 GHz. The Taconic substrate, RF60-0600, was used to design the filter. The essential design parameters of the substrate are as follows:- $\varepsilon_r = 6.0$ $h = 1.52$ mm, and $\tan\delta = 0.002$. The effect of dispersive nature was neglected as the substrate used exhibits nearly nondispersive property in 9 GHz frequency region.

The design parameters obtained from (4)-(5) are summarized in Table I. All lumped inductors from ECKO (model 0603CS) were used in the design. To simulate the design circuit, the inductor model detail acquired from the manufacturer website was developed in the Advanced Design System™ software. Applying the obtained parameters calculated from the design equations, the circuit simulation results met all desired targets. Then the layout and EM simulation were performed with Momentum™. Special care was taken during the layout process, especially at all microstrip discontinuities. In our layout, the ground inductors were implemented with short stubs.

Fig. 5 a) and b) show the photograph of the PCB prototype and the layout, respectively. The circuit size excluding the input and output SMA connectors is around 2.2×1.8 cm^2. The measurement was performed with an HP8720C Vector Network Analyzer test system calibrated from 0.1 to 8 GHz with an SOLT calibration technique. HPVEE6.0™ software was used to collect the experimental data via GPIB card. Momentum™ and Matlab® were used for simulation, data post processing, and display.

The EM (dot line) and measured (thick line) results of the microstrip filter are shown in Fig. 6. A close view of the filter response at the passband is also plotted in the inset of Fig. 6. The measured results are in good agreement with the simulated results. The difference in filter response appeared is expected to caused by the in-house fabrication tolerance. From Fig. 6, the filter achieves bandwidth of 120 MHz at f_0 of 2.45 GHz. A 2.1 dB insertion loss is obtained at the center frequency. The f_{Z1} and f_{Z2} are occurred at 1.78 and 2.6 GHz, respectively. Large stopband response is obtained, which is less than -18 dB from 2.8 to 8 GHz. Harmonic responses at $2f_0$ and $3f_0$ are kept low, which are lower than –32 and -26 dB, respectively.

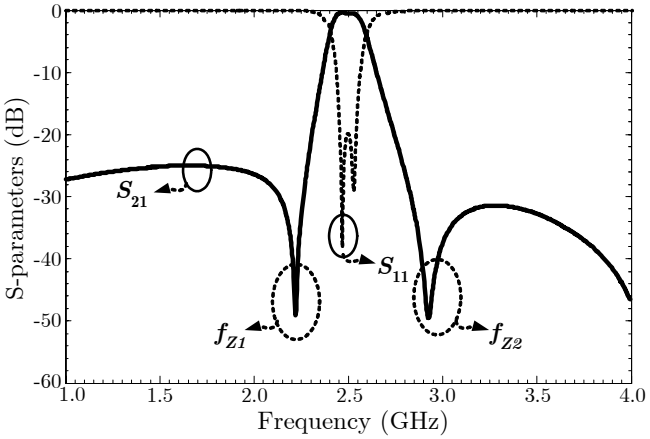

Fig. 4. Simulated frequency responses of the proposed narrowband ring filter based on coupling-fed and SIR.

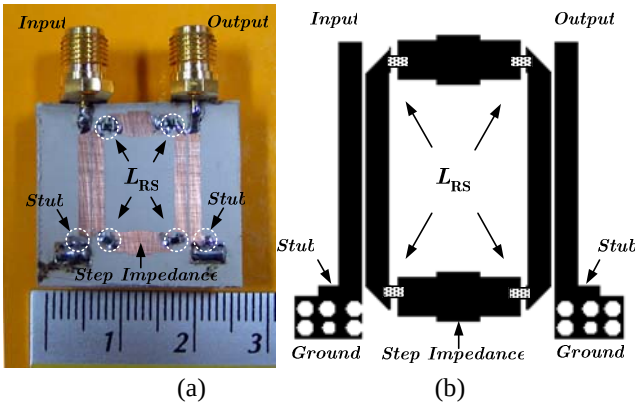

Fig. 5. (a) PCB photograph and (b) the circuit layout of the proposed ring bandpass filter.

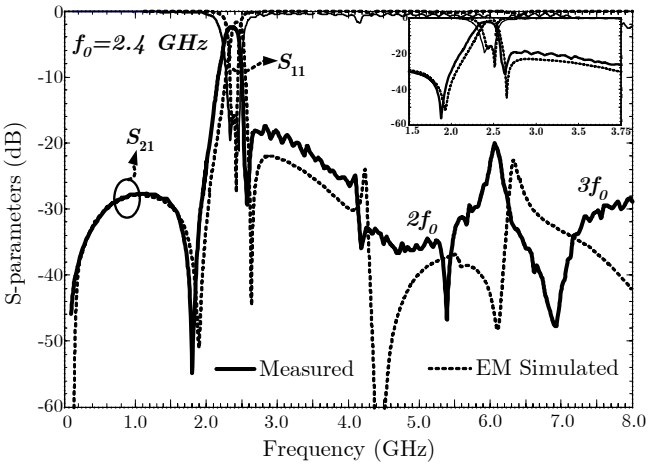

Fig. 6. Comparisons of EM simulated (------) and measured results (——) of the proposed ring bandpass filter.

IV. CONCLUSION

A novel narrowband coupling-fed ring filter based on inductive compensated technique and step-impedance resonator has been proposed. Sharp transition in filter response and hence narrow passband is achieved with introducing SIR in the loop resonator. A simple design approach for the filter has been presented and proven with the design microstrip filter at 2.4 GHz for 5% percentage bandwidth. It is believed that the technique is highly suitable for modern wireless communication systems.

ABSTRACT

This paper presents a new dual-band bandpass Filter using stepped-impedance and capacitive load hairpin resonators for mobile systems. Based on resonant characteristics of a stepped-impedance resonator and load capacitive, the second resonant frequency can be tuned over a wide frequency range by adjusting its structure parameters. The stepped-impedance resonators and the resonators use capacitive load characteristic with a cross-coupled structure have been employed to build up a bandpass filter at center frequencies of 900 MHz and 1800 MHz. The experimental results of the fabricated filter agree very well with simulation expectations using IE3D package. The proposed filter has good performances and also small sizes.

Keywords: Stepped-impedance, cross-coupled filter, dual-band, bandpass filter, load capacitive.

1. INTRODUCTION

Nowaday there is increasing in the demand of using mobile. For mobile applications through the second-generation GSM and the third-generation WCDMA mobile communications, the RF transceivers should be able to receive and transmit for dual-band *i.e.* at 900 MHz and 1800 MHz. A GSM 900/1800 MHz dualband BPF was develop by using microstrip open-loop resonators.It is, of course, not suitable for constructing a dual - frequency filter of which the second frequency is not twice the first one.Thus, the resonators have to be modified. Intuitively, dual-band filters can be implemented by combination of two filter,which are design different passbands [1]-[2]. it can controll center freqyency by changing impedance therefor it development by parallel step-impedance for good mor than basic step-impedance and development hairpin resonators step-impedance for small struckture and good response. Open loop resonators use load capacitive for reduce size and tune first harmonics, therefore it has been developed to be a parallel a coupled line filter structure for good responses and smaller sizes [1]-[3]. These proposed filters employ coupled-line structures, therefore the sizes are considerably large and high selectivity characteristics can not be obtained. In this paper a crosscoupled structure with steppedimpedance resonators (SIR) and load capacitive has been used to design a dualband bandpass filter (BPF).

2.CROSS-COUPLED,STEPPED-IMPEDANCE AND LOAD CAPACITIVE RESONATORS

Design procedure for A dual-band bandpass filter using step-impedance and load capacitive hairpin resonators for mobile system it useing theory of load capacitive stepped-impedance and cross-couple .The theory load capacitive stepped-impedance and cross-couple structures have been discussed in the following.

2.1 Open-loop resonators use capacitive load

In this procedure useing theory of open-loop resonators use capacitive load.Fig. 1 shows the geometrical diagram of the miniaturize hairpin resonators and it equivalent circuit.These resonators are characterized by fundamental (odd-mode) and firstspurious (even-mode) resonances due to their coupleline section. As derived in the equations that describe the even-mode and odd-mode resonance are

$$\tan\frac{\theta_s}{2} = \frac{Z_{oo}}{Z_s}\cot\theta_{oo}$$

$$\cot\frac{\theta_s}{2} = -\frac{Z_{oe}}{Z_s}\cot\theta_{oe} \qquad (1)$$

Where θ_s is the electrical length of transmission line and Z_s is the characteristic impedance of the transmission line odd-mode and even-modecharacteristic impedance and corresponding coupling angle of the coupled-lines are Z_{oo},Z_{oe} and θ_{oo},θ_{oe} respectively.For this case the ratio of the couple-line characteristic impedance is

$$R = \frac{Z_{oo}}{Z_s} \quad (\text{at } f = f_0 \text{ odd-mode})$$

$$R = \frac{Z_{oe}}{Z_s} \quad (\text{at } f = f_1 \text{ even-mode}) \qquad (2)$$

Form Eq. (2) impedance ratio of greater than one causes the resonator to resonate at a frequency higher than initial fundamental frequency.Impedance ratio ofless than one makes the resonators to resonate at a frequency lower than initial fundamental frequency.These behaviors show that there is a special mechanism for resonance frequency tuning being offered by the internally couple-line hairpin

resonators.Acompact size of hairpin resonator can be designed if the initial frequency chosen for the half-wavelength resonator is higher than the desired operating frequency,with impedance ratio less than one .In structure of open-loop resonators use capacitive load electrical length θ_s are set to be λ/4.

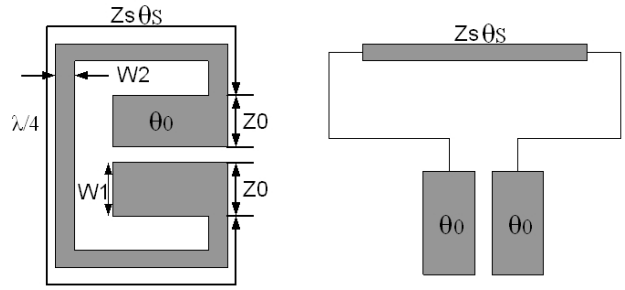

Fig. 1: *Schemetic of the miniaturize hairpin resonator and equivalent circuit of SIR.(a) Geometrical diagram of the miniaturized hairpin resonator.(b) An equivalent circuit of SIR with internal couple line.*

After using equations find the Open-loop resonators use capacitive load but the resonance frequency of first harmonic is not equal to the designing see in figure 2.

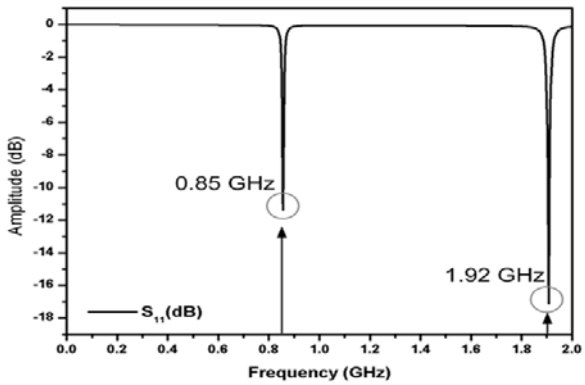

Fig. 2: *A simulated response of return loss.*

So ,we use a step-impedance technique to correct the first harmonic

2.2 A step-impedance line

Fig. 3 shows a basic stepped-impedance structure with a λ/4 length at lower frequency resonant, when electrical lengths θ_1 are set to be λ/4 respectively. Values of Z_1 and Z_2 represent the characteristic impedances of transmission lines that are implemented as a short circuited and open-circuit ends, respectively [1], [2]. A value *R* is the ratio between Z_1 and Z_2 .

$$R = \frac{Z_2}{Z_1} \tag{3}$$

The value of *R* can be *R*>1or *R*<1, however, it is found that we can control the first harmonic far away from the fundamental center frequency when *R* >1.

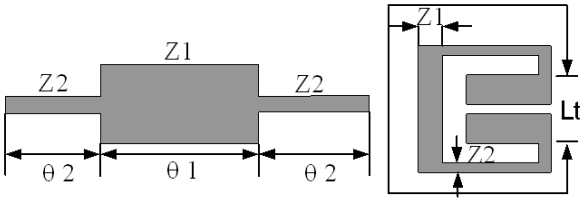

Fig. 3: *A structure of step-impedance line resonator*

The first harmonic can be found by the following equations

$$R = \tan^2 \theta_0$$
$$\theta_0 = \tan^{-1} \sqrt{R}$$
$$f_1 = \frac{\pi}{2 \tan^{-1} \sqrt{R}} f_0 \tag{4}$$

when f_1 is the first harmonic and f_0 is the fundamental frequency. A particular return loss response of the stepped-impedance structure can be obtained using IE3D program as shown in Fig.4.

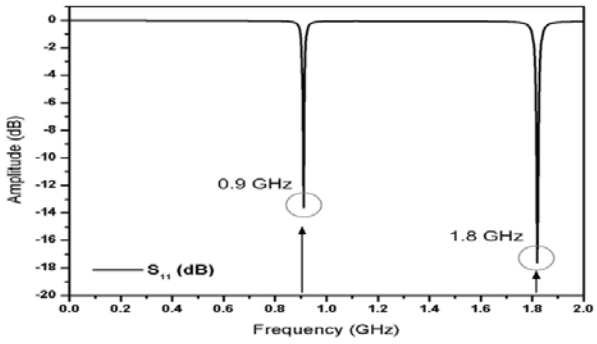

Fig. 4: *A simulated response of return loss stepimpedance.*

2.3 Hairpin-line resonators

The dual-band 900/1800 MHz line resonators are design to operate at the center frequency of 900 MHz.Due to the resonators are design at half wavelength at low frequency , so they generate the first harmonic at 1800 MHz.After that , the conventional line resonators are renovated to hairpin-line resonators as show in Fig.5 it has response of frequency at 900 MHz and 1800 MHz show in Fig.6

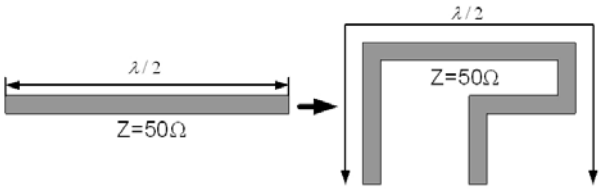

Fig. 5: *A structure of* hairpin-line resonators

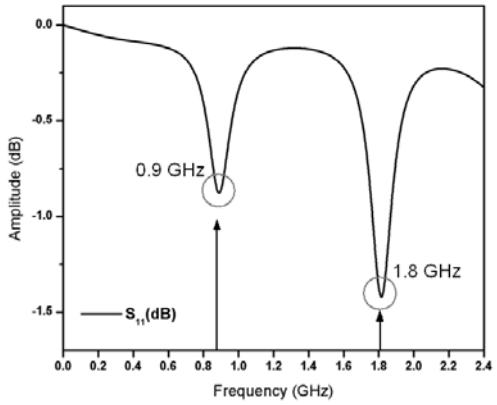

Fig. 6: *A simulated response of return loss* hairpin-line resonators.

2.4 A cross-couple structure

Theory of cross-coupled filter structures can be found in [4], [5]. This paper uses four stepped-impedance resonators in a cross-coupled structure to create a bandpass filter operated at centre frequencies of 900 MHz and its first harmonic of 1800 MHz as shown in Fig.7. The resonators must be properly placed so that four appropriate couplings can be obtained with a Chebyshev response. The equations of coupling coefficients K_{ij} can be found as following [6].

$$K_{12} = K_{34} = \frac{FBW}{\sqrt{g_1 g_2}}$$

$$K_{23} = \frac{FBWJ_2}{g1}$$

$$K_{14} = \frac{FBWJ_1}{g_1} \qquad (5)$$

$$Q_{ei} = Q_{eo} = \frac{g_0 g_1}{FBW} \qquad (6)$$

where FBW is the fractional bandwidth, g_0, g_1 and g_2 are the element values and J_1, J_2 are the admittance inverters in its equivalent circuit of the low-pass prototype. Q_{ei}, Q_{eo} are external quality factors of the resonators at the input and output.

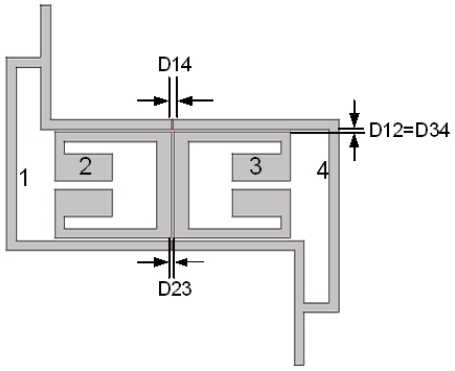

Fig. 7:*The proposed cross-coupled filter.*

3. IMPLEMENTATION AND RESULTS

The proposed filter has been designed on a substrate of GML-1000 with ε_r of 3.2, thickness of 0.762 mm and loss tangent of 0.004. The couplings between two resonators can be calculated by IE3D simulation program [7]. The stepped-impedances have been set to be Z_1 = 37.30 Ω and Z_2 = 50 Ω. Form equation (3)-(4), we find that the first harmonic is at frequency of 1800 MHz when the centre frequency is at 900 MHz. The line widths w of 37.30 Ω and 50 Ω are 2.87 mm and 1.83 mm, respectively. The values of θ_1 and θ_2 are calculated to be 37.3092 mm and 16.64 mm, respectively. The 50 Ω port has a width of 1.83 mm. and resonators use load capacitive has Zs 55 Ω Zoe 61.74 Ω Zoo 55 Ω are corresponding to the line widths w1 5.22 mm and w2 .083 mm. The 50 Ω port has a width of 1.83 mm. Form equations (1)-(2) we obtain a lowpass prototype of the proposed filter: g_0=1, g_1=0.7533, g_2=1.16552, j_1= -0.4513, j_2 =1.05789. The external quality factors are $Q_{ei} = Q_{eo}$ =21.5225. The coupling coefficients between the adjacent resonators can be found to be $K_{12} = K_{34}$ = 0.037353, K_{23} = 0.03176, K_{14} = 0.020974.

The next step of the filter design is to determine the couplings between adjacent resonators. It had been found that each of the three coupling structures has two dominant resonant frequencies, which are split off from the resonant condition as normally shown in Fig.4. The couplings between resonator i and j, K_{ij}, can be then calculated by

$$K_{ij} = \frac{f_b^{\,2} - f_a^{\,2}}{f_b^{\,2} + f_a^{\,2}}$$

where f_a and f_b are the lower and higer split resonant frequencies of a pair of couple resonators.

The distances of the final filter structure can be found to be D_{14}=0.3mm, D_{23}=0.4mm, and D_{12}=D_{34}=0.5 mm. Finally, we have simulated the values of return loss and insertion loss as results shown in Fig.8.

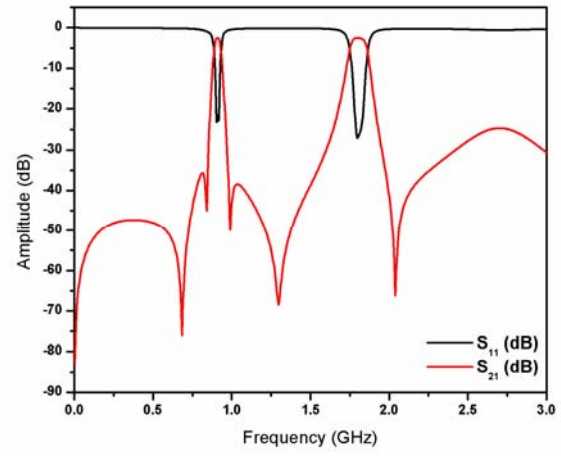

***Fig.8**: Simulated responses of S_{11} and S_{21}.*

From Fig.8, at the 900 MHz band we have S_{11}=-21 dB, S_{21}=-2.557 dB with a bandwidth of 60 MHz and at the 1800 MHz band we obtain S_{11}=-26 dB, S_{21}=-2.525 dB with a bandwidth of 180 MHz.

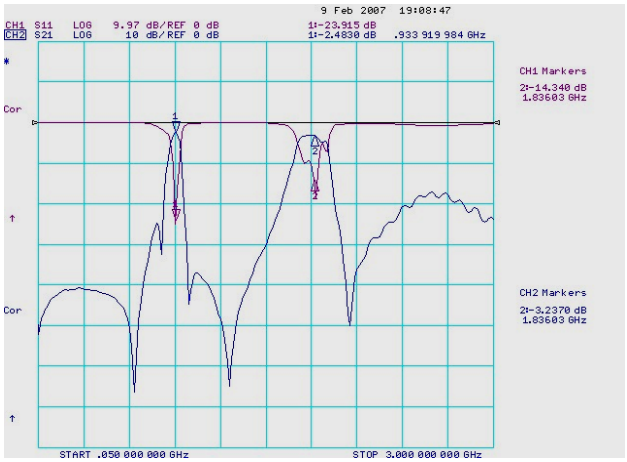

Fig.9: *Measured responses of S_{11} and S_{21}.*

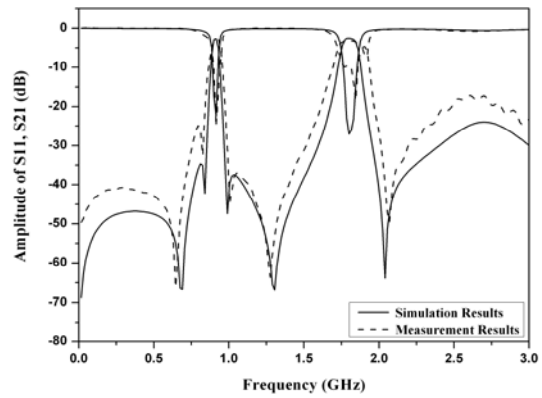

Fig.10: *Comparison between measured and simulated responses.*

Fig.9 shows measured responses at frequency of 900MHz with S_{11} = -23.91dB, S_{21}=-2.48dB and at frequency of 1800 MHz with S_{11}=-14.34 dB, S_{21}=-3.23dB.

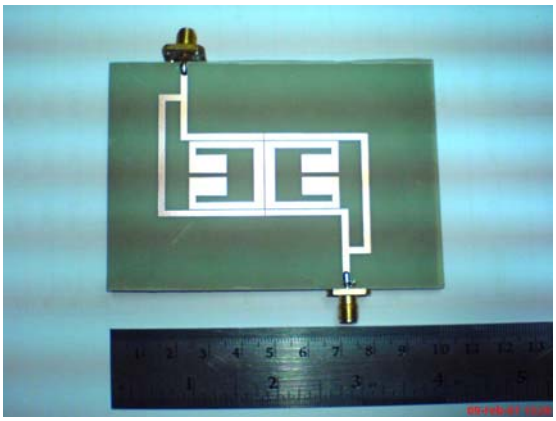

***Fig.11:** A photograph of the proposed BPF.*

Fig.10 comparisons between simulated and measured performance are shown.The photograph of the fabricated filter is shown in Fig.11.

4. CONCLUSIONS

A dual-band bandpass filter using cross-coupled stepped-impedance hairpin resonators for mobile systems has been proposed to operate at frequency bands of 900 and 1800 MHz. The results show good agreement between simulation and measurement. The proposed filter also demonstrates good performances, which it can be applied for other interesting frequency operation bands.

***Abstract*-The possibility of an acousto-optic frequency/tone decoder by means of a practical approach has been demonstrated by making use of a simple electronics feedback circuit to stabilize the sensitivity of fiber ring resonator. The applications of such a device have been proposed.**

I. INTRODUCTION

All-optical system is one of the key factors to maximize the speed of the optical systems in many applications such as optical communications and optical signal processing. One approach of such a system makes use of the replacing the electronics components with the optical components. The idea of imitation electronics devices in terms of optoelectronics or all-optical devices seems to be a simply way to research [1]-[3]. For instance, the microwave frequency optoelectronics tone decoder was firstly proposed in 1996 [4]. Consequently, the theory of this device was widely investigated [5],[6]. However, the practical demonstration of such a device has not yet been demonstrated due to the characteristic of high sensitivity of fiber ring resonator, which is the main part of the device. In this paper, we, for the first time to our knowledge, demonstrate the possibility of a practical device. The simple technique of employing a feedback electronics circuit to stabilize the output light intensity of fiber ring resonator is described. In addition, the concept idea to make use of this device in the applications as photonic switching, external modulator, and optical wavelength selection/multiplexer, is proposed.

II. SYSTEM DESIGN CONFIGURATION

As shown in figure 1, the configuration of an acousto-optic frequency decoder is a hybrid system consisting of optical and electrical parts. The optical part is composed of an ordinary fiber ring resonator with an acousto-optic (AO) phase modulator in its close loop. For very high frequency up to a few gigahertzes, the AO phase modulator can be an AO fiber transducer using zinc oxide (ZnO) circumferentially coated on an optical fiber surface [1]. The AO phase modulator is controlled by an electrical high frequency trigger signal. The electrical part is an electronics feedback system that supplies the DC voltage to a cylindrical PZT, which is wrapped by some part of the fiber in the loop. This technique is to set up the ring resonator at the phase resonance condition and also to compensate the ring resonator from the environment sensitivity. The key to lock up the desired electrical frequency arises from the structure of the phase modulator. By employing the theory of the acousto-optic resonator [2] as well as of the fiber ring resonator [4], the device performance at one particular desired frequency, defined from the thickness of ZnO layer, can be controlled by means of the output light intensity (I_o).

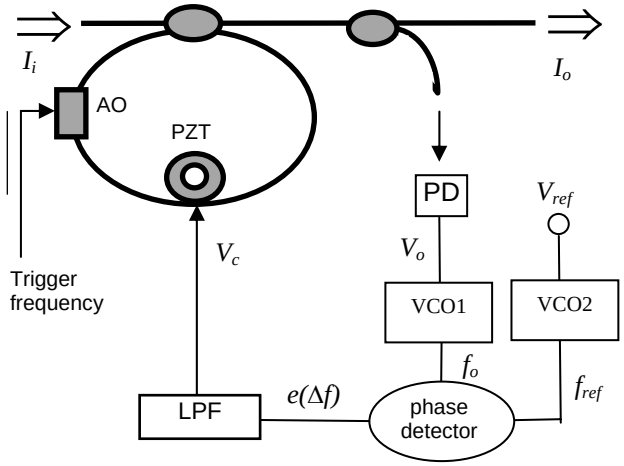

Figure 1. Schematic of an acousto-optic frequency decoder.

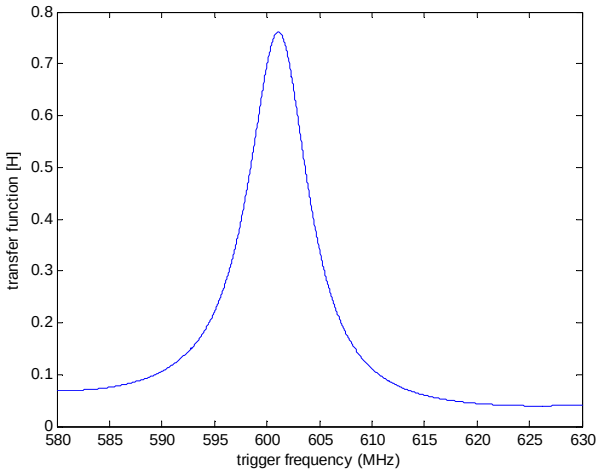

Figure 2. The output light intensity (I_o) as a function of frequency trigger.

Figure 2 shows an example of the output light intensity (I_o) when the electrical signal with different frequency is applied to

the AO phase modulator. As can be seen, although the input light (I_i) always remains at fix intensity, the output light will emerge only if an appropriate frequency is applied to the AO phase modulator.

In practice, the fiber ring resonator is very much sensitive to the environment [3]. Then, the electronics feedback system as shown in figure 1 is a need to stabilize the output light I_o. The stabilization circuit consists of two voltage control oscillators (VCO1 and VCO2), phase detector and active low pass filter (LPF). To photo detector (PD) defines the voltage (V_o) which is related to the reference voltage (V_{ref}) found from the characteristic point of fiber ring resonator so that the desired output light intensity is locked.

To verify the possibility of output light stabilization, the system as shown in figure 1 without an AO phase modulator is experimentally examined. The practical parameter values of VCO (VCO1 and VCO2) should be kept at low frequency to minimize the sensitivity. In the experiment, the minimum frequency of about 15 Hz is chosen. The maximum frequency is limited by the cut-off frequency of the active low pass filter (LPF) of about 140 Hz. The capture range of VCOs is varied between 20-40 Hz and the lock range is varied between 10-50 Hz. The phase detector employs an exclusive-OR gate. The characteristic between the DC voltage and frequency of VCO is illustrated in figure 3.

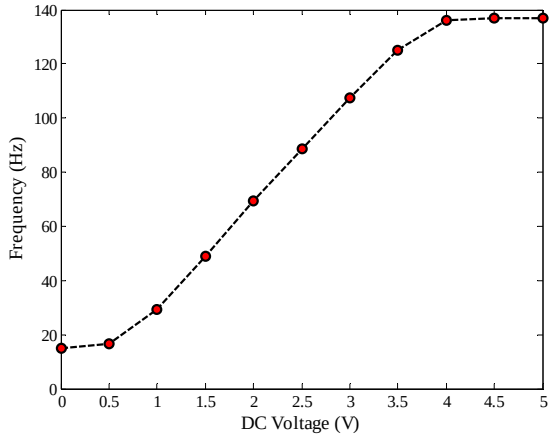

Figure 3. The characteristic between the DC voltage and frequency of VCO

The fiber ring resonator used in this experiment employs a single mode fiber and a 3-dB directional coupler. Some part of fiber in the loop was wound around a piezoelectric cylinder (PZT) that can expand radically to control the phase of the ring loop. A polarization controller (PC) is used to counter birefringence present in the resonator ring. Thus the polarization entering the coupler and the fiber ring will be in the same state. A He-Ne laser (λ = 633 nm) was used to excite the fiber ring resonator. The output light intensity of the ring resonator by means of electrical voltage (V_o) is sent through VCO1 and is compared to a reference signal from VCO2 (V_{ref} or V_r) corresponding to the desired operating point. If the frequency output from VCO1 (f_o) and the frequency output from VCO2 (f_{ref}) are different, an error signal $e(\Delta f)$ integrated by LPF will produce the DC voltage signal (V_c) to drive the piezoelectric cylinder (PZT). This mechanism makes compensation of the appropriate fiber length (phase shift) in the ring loop. Consequently, the output light intensity is stabilized even though the ring resonator is perturbed from the environment.

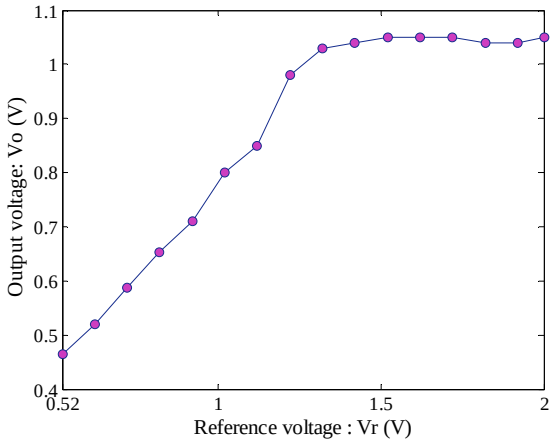

Figure 4. The relationship between the reference voltage and output voltage.

Figure 4 shows the output light intensity by means of output voltage (V_o) when the reference voltage (V_r) is varied. Once the operating point of the ring output is set at the lowest value, ie., V_r = 0.52 volt. As the reference voltage is increased, the output voltage is increased according to the characteristic of transfer function of the ring resonator itself until it reaches the maximum value at which the output voltage remains though the reference voltage keeps increasing. This experiment result verifies the possibility of system stabilization. In another word, the environment sensitivity is eliminated.

III. APPLICATIONS

A. Photonic Switching

The transfer function of an acousto-optic frequency/tone decoder, for example, shown in figure 1 is the characteristic of the photonics switching. The light signal from the input port (I_i) can be switched to the output port (I_o) only when an appropriate trigger signal (frequency in this case) is enabled. The speed of the switch depends on the characteristic of an AO transducer and the trigger frequency. If the ZnO-coated fiber [2] is performed, the speed in terms of gigahertz can be achieved.

B. External Modulator

From the transfer function of a fiber ring resonator as shown in figure 5, if the operating point is locked in the region of non-stable output, the small electrical frequency (depending on the AO phase modulator) applied to the acousto-optic frequency/tone decoder, shown in figure 1, will result in modulating the output light signal. The schematic of such a

device is very simple for an external light modulator in comparison with the electronic (internal) modulator when high frequency up to a few gigahertzes is considered. In addition, the response time of the modulation is quite fast [3].

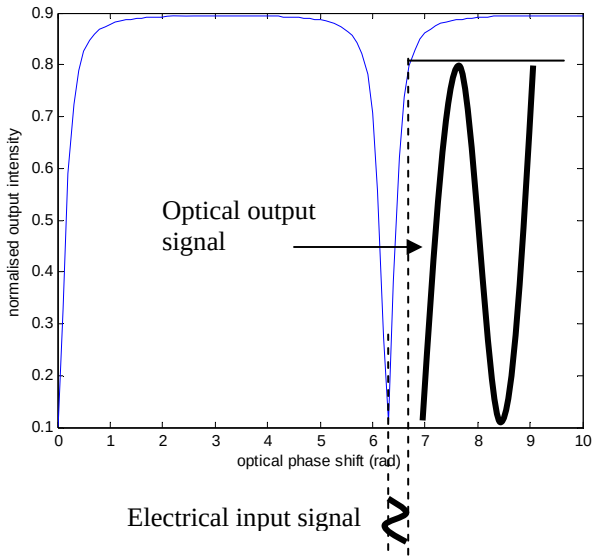

Figure 5. The concept idea of an external modulator.

C. Wavelength Selection/Multiplexer

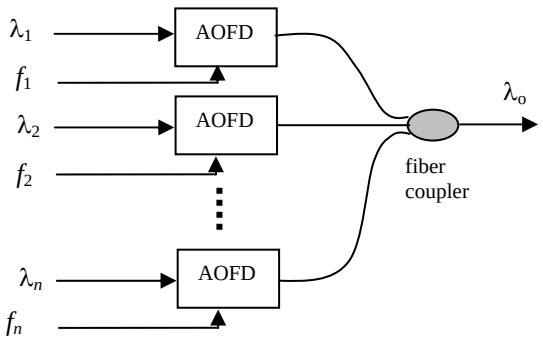

Figure 6. Structure of an optical wavelength selection.

The concept idea of an optical wavelength selection is expressed in figure 6. AOFD is an acousto-optic frequency/tone decoder which has the same structure as shown in figure 1. The input optical signal of each AOFD can be any wavelength, ie., λ_n with n an integer. Each AOFD needs trigger electrical signal at particular frequency to operate the AOFD (to control the output light). The output of all AOFDs is connected to an ordinary fiber coupler. It should be noted that the practical device needs an electronic feedback circuit with appropriate reference signal (V_r) to maintain the output of each AOFD at the desired operation. Once the output condition of each AOFD is set, the output signal corresponding to the input wavelength (λ_n) will emit when an electrical signal with appropriate frequency (f_n, n is integer) of each AOFD is enable. After passing through the fiber coupler the final optical signal is received. According to the characteristic of an AOFD, the output optical wavelength will depend on the trigger frequency (f_n). Consequently, the output wavelength can be selected. If more than one appropriate electrical signal is applied, more than one wavelength will be multiplexing at the output as the result.

IV. CONCLUSION

A simple electronic feedback system in the fiber ring resonator is experimentally demonstrated for the first time. This verify the possibility of using the fiber ring resonator in company with optical phase modulator in the fiber loop to sustain the desired output light by minimizing the sensitivity of the ring resonator due to the environmental effect. The principle concept for making use of such a device in terms of photonic switching, external modulator, and wavelength selection/multiplexer, have been explained.

ACKNOWLEDGMENT

The author would like to thanks Mr. Sommart Sang-ngern, a Ph.D. student at Mahanakorn University of Technology, for his great effort in making the successful experiment.

***Abstract*- This paper studies the methodology of WDM Networks logical design, by using TOT (Telephone Organization of Thailand) backbone network for connecting between sub-networks. Bellman-Ford's algorithm is used for computing and simulation for optimal logical design of WDM network. There are three main parameters consider in this paper. Including minimum cost, shortest-path routing and re-computing of minimum cost to find out final shortest path. Furthermore, we have compared the result from logical computation with physical topology. Existing backbone optical network and traffic require of TOT are used as raw data for this study.**

I. INTRODUCTION

Design of WDM Backbone Network for connecting between Sub-networks is important. Not only considering about traffic of sub-networks all around Thailand but also the operating cost and losses in fiber optic also. Backbone network logical design is chosen for study how to make an optimal and efficiency routing in carrying increasing amounts of commercial traffic. Reliability and steady performances have become critical factors when designing and managing those networks. Large network today offer Service Level Agreements (SLAs) covering delay, port availability and losses across their network which must be maintained even if the network experiences congestion or failure. This provides strong incentives for designing conditions, i.e., fluctuating traffic patterns and intensities or topological changes caused by link and node failures [1].

In this paper, our focus is on logical design of TOT Backbone Network by considering three main parameters, Minimum Cost, Shortest-Path Routing and Re-computing of Minimum Cost in case of major category of failures,

II. ROUTING ALGORITHM

A. *Bellman Ford Algorithm*

Bellman-Ford Algorithm makes each node periodically broadcast its routing tables to all its neighbors. . This algorithm have to maintain the distance tables (which is a one-dimension array—"a vector"), which tell the distances and shortest path to sending packets to each node in the network. The information in the distance table is always updated by exchanging information with the neighboring nodes [2]. The number of data in the table equals to that of all nodes in networks (excluded itself). Each data contains the path for sending packets to each destination in the network and distance/ or time to transmit on that path (we call this as "cost"). The measurements in this algorithm are the number of hops, latency, the number of outgoing packets, etc.

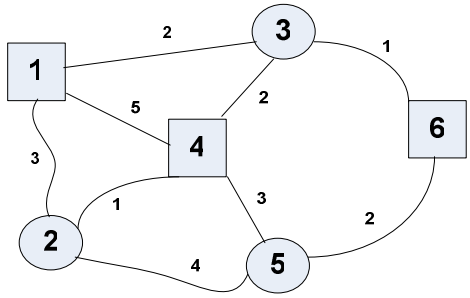

Figure 1. Sample Network with link cost

In Fig.1 if we would like to find the shortest-path between Node 2 to Node 6, from Node 2 that Node 1, 4 and 5 are neighbors and we can expect that the shortest link cost form Node 1, 4 and 5 to Node 6 are 3, 3 and 2 consequently. If we route through Node 1, the total cost is 3+3 which is equal to 6, on the other hand if we route through Node 4, the total cost is 1+3 which is equal to 4 and if we route through Node 5, the total cost is 4+2 which is equal to 6. Thus the shortest-path between Node 2 to Node 6 is routed through Node 4.

The starting assumption for distance-vector routing is each node knows the cost of the link of each of its directly connected neighbors. Next, every node sends a configured message to its directly connected neighbors containing its own distance table. Now, every node can learn and update its distance table with cost and next hops for all nodes network. Repeat exchanging until no more information between the neighbors.

Consider a node 2 to the destination node 6, the minimum cost can be found form

$$\begin{aligned} D_2 &= \min\{C_{21}+D_1, C_{24}+D_4, C_{25}+D_5\} \\ &= \min\{3+3, 1+3, 4+2\} \\ &= \min\{6,4,6\} \\ &= 4 \end{aligned} \quad (1)$$

Where C_{ij} is link cost between node i to node j, for example $C_{13}=C_{31}=2$ and $C_{ii}=0$. So the minimum cost from node 2 to node 6 is equal 4. Thus, we can calculate the other routing as follow: From node 1 to node 6

$$D_1 = \min\{C_{12} + D_2, C_{13} + D_3, C_{14} + D_4\} \quad (2)$$

While form node 4 to node 6

$$D_4 = \min\{C_{41} + D_1, C_{42} + D_2, C_{45} + D_5\} \quad (3)$$

For d, the distance to destination, we can consider Bellman-Ford Algorithm as follow:

1. Initial state

$$D_i = \infty \quad \text{Where } i \neq d \quad (4)$$

$$D_d = 0 \quad (5)$$

2. Update state (to find out the shortest-path to destination via neighbors) where $i \neq d$

$$D_i = \min\{C_{ij} + D_j\} \quad \text{For } j \neq i \quad (6)$$

This equation suggests that the form of neighbor-to-neighbor communication that will take place in the Distance-vector (DV) routing [3] - each node must know the cost of each of its neighbors' minimum-cost path to each destination. Hence, whenever a node computes a new minimum cost to some destination, it must inform its neighbors of this new minimum cost.

$$D_{ij} = 0 \quad (7)$$

$$D_{ij} = \min(C_{ik} + D_{kj}) \quad (8)$$

D_{ij} is the minimum cost from node i to destination node j. When update state node i will distribute vector $\{D_{i1}, D_{i2}, D_{i3}, ...\}$ to its neighbors.

B. Link Cost Calculation

In this paper, we calculate the link cost from 3 factors: the number of wavelength in each physical link N_λ, Total losses (L), and Distance (d) between nodes. The formula can be represented as

$$Link\ Cost = A + B + C \quad (9)$$

Where

$$A = (1/N_\lambda)^* w_1 \quad (10a)$$

$$B = L * w_2 \quad (10b)$$

$$C = d * w_3 \quad (10c)$$

Replace A, B, C in (9) with (10a)-(10c), Thus

$$Link\ Cost = ((1/N_\lambda)^* w1) + (d * w2) + (L * w3) \quad (11)$$

where
- N_λ is Number of wavelength
- d is distance (km)
- L is Losses
- w_1 is weight factor in term of number of wavelength
- w_2 is weight factor in term of distance
- w_3 is weight factor in term of losses

The total losses are from Fiber loss (0.2525 dB/km), Connection losses (0.5 dB/1 connection point) and Margin (4 dB/section). The weight setting are $w_1+w_2+w_3=1$ and $w_1=0.5$, $w_2=0.3$, $w_3=0.2$. The major factor of this study is on number of wavelength because it provides the minimum link cost and it is the main parameter in expansion/reduction of WDM capacity while the physical distance is not changed.

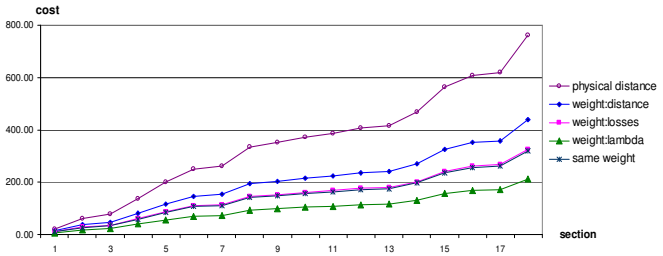

Figure 2. Link cost calculation in different weight setting

From (11) we will get backbone network with link cost as in Fig. 3

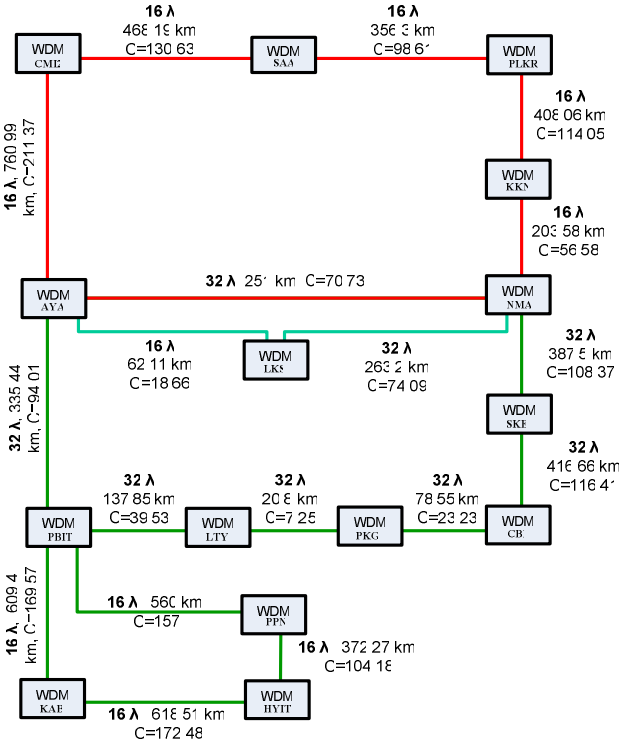

Figure 3. TOT Backbone Network with link cost

C. *Minimum Cost Calculation*

For all node i, the assign value are (n,D_i) where n is the shortest next hop and D_i is the minimum cost from node i to node j as (6). In case of none specific destination we have to assign n equal -1 for the first time calculation. The starting assumption for distance-vector routing is each node knows the cost of the link of each of its directly connected neighbors. Next, every node sends a configured message to its directly connected neighbors containing its own distance table. Now, every node can learn and update its distance table with cost and next hops for all nodes network. Repeat exchanging until no more information between the neighbors.

D. *Shortest Path Routing*

From *section C*, after exchanging cost until no more information between the neighbors, we will get shortest-path routing. In this paper we consider the condition from equation (7) and (8) and use Matlab to calculate Minimum Cost and Shortest-path.

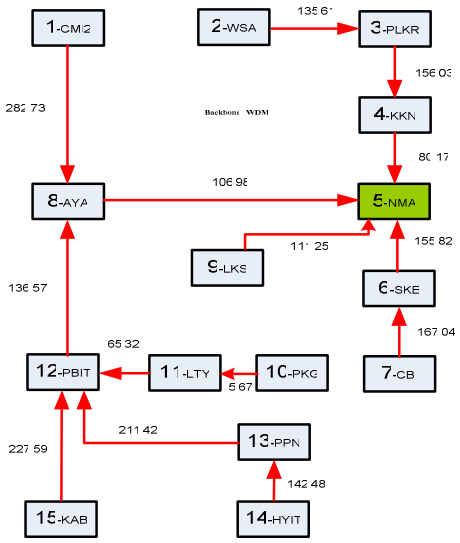

Figure 4. The shortest-path routing to destination Node 5

Fig. 3 show the example of calculate result to route a path connection between other nodes to destination node 5 with the shortest-path and minimum cost.

E. *Minimum Cost Re-computation*

It is beneficial to discuss the concept of critical links and our approach for finding them. Our goal is to compute a routing solution that protects the network performance against the failure of links that impact the network most on failure. In case of physical link failure, we have to re-routing path to the other route. We can follow up the process of *section D* by generate the link cost of failure to infinity and re-start calculate shortest-path and update its distance table with cost and next hops for all nodes network.

Fig. 4 shows the new shortest-path routing to destination Node 5 when the link failure occur between node 8 and node 5. The new path will be routed to avoid the broken link but the re-calculation is still being base on Bellman-Ford algorithm with the minimum link cost.

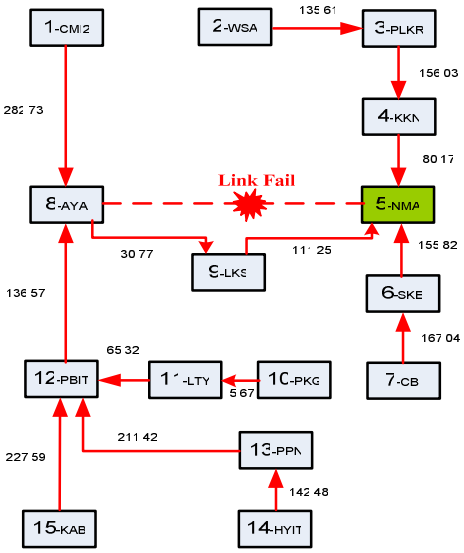

Figure 5. The new shortest-path routing to destination Node 5 with link failure

III. NUMERICAL RESULTS

In this section, we present the curves to compare the results of Physical distance and Logical Link Cost and between Logical and Physical Hop count. The parameters of node source to destination node, we have chosen node 5 and node 14 as destination nodes. Fig. 6 shows the comparison between Physical and Logical link cost of node i to node 5 and node 14 and Logical and Physical hop count. The same hop count on both techniques shows that the algorithm will provide the optimize path that match to the real network. Fig. 7 shows the Cost of distance and hop count in link failure between node 11 and node 12 that sorted by physical distance in each section. Fig. 8 shows the Cost of distance and hop count in link failure between node 5 and node 8 that sorted by physical distance in each section as shown.

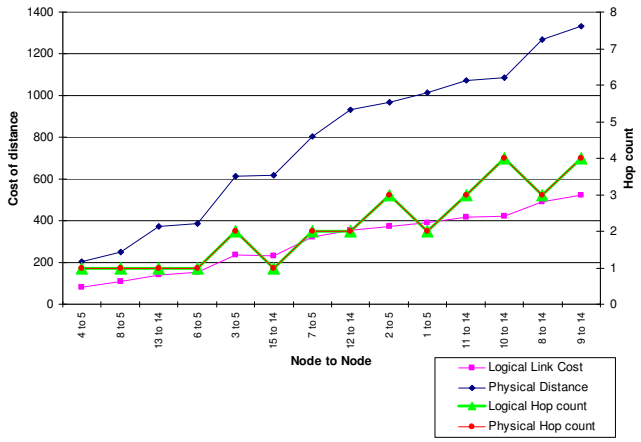

Figure 6. The comparison between Physical and Logical Cost Distance and Hop count

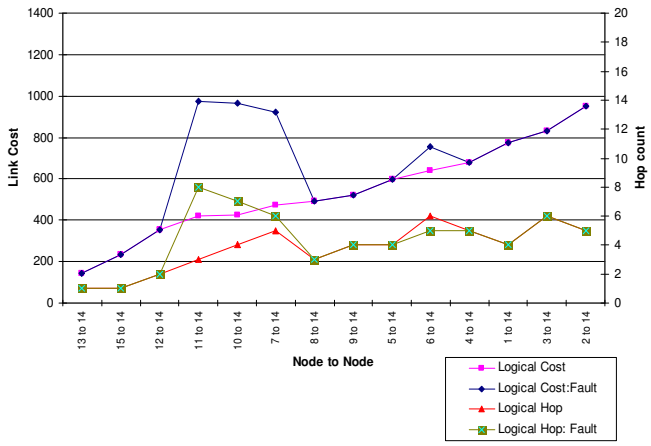

Figure 7. The new shortest-path routing to destination Node 5 with link failure

IV. CONCLUSIONS

Shortest-Path routing is introduced into design logical network for connecting between Sub-networks. Bellman-Ford's Algorithm is used for computing and simulation for optimal logical design of WDM network by considering in the link cost that can be calculated in term of number of wavelength in majority. Three main parameters consider in this paper including Minimum Cost, Shortest-Path Routing and Re-computing of Minimum Cost to find out final shortest path. Furthermore, the expansion or reduction of WDM network capacity can be changed by number of wavelength that updated link cost and new shortest-path.

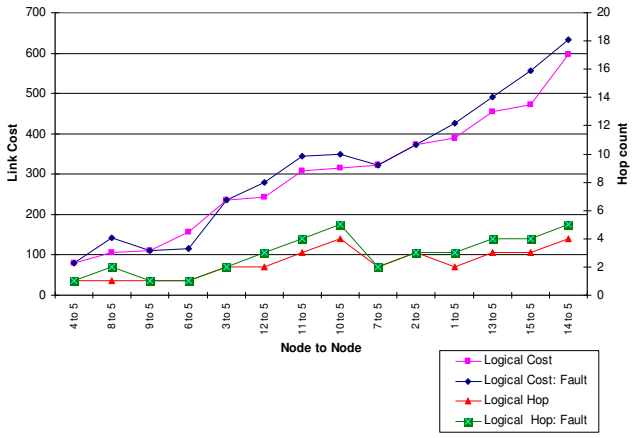

Figure 8. The new shortest-path routing to destination Node 5 with link failure

***Abstract*-This paper presents a complete numerical analysis of co- and counter-propagating pump power in distributed Raman amplifier (DRA) for remotely pumped long haul optical fiber communication system (OFCS). The mathematical model to calculate the signal gain due to DRA is described. The intrinsic parameters of standard single mode fiber (SMF) are used to simulate the mathematical model DRA. Signal gain and signal propagation through the transmission fiber, with and without Raman gain using co- and counter-propagating pump power are investigated. The presented numerical analysis can be used as a design tool of long haul transmission link using DRA, especially to calculate the signal power budget of the long haul OFCS incorporated with a hybrid EDFA / DRA.**

***Keywords*-** Distributed Raman amplifier, Hybrid EDFA / DRA, Long haul OFCS.

I. INTRODUCTION

DRAs have emerged in recent years as a key technology for the modern optical fiber communication system [1]. The broad bandwidth of DRA makes it attractive for use in high capacity, long haul transmission system [2]. DRA expands the signal bandwidth through multi-pumping wavelength allocation [3] and offers improved noise characteristics [4]. Because of the high importance of DRA in modern long haul OFCS, a detailed analysis tools is essential in order to obtain the results of the system performance. Both analytical [5] and numerical [6] models of DRA have been reported. Co- [7] and counter-propagating [8] pumping schemes have been reported to maximize the power budget of remotely pumped long haul OFCS incorporated with hybrid EDFA / DRA. The position of inline Erbium doped fiber amplifiers (EDFAs) in the remotely pumped long haul OFCS are dependent on the pumping scheme of DRA. So, an analysis of power budget improvement due to DRA with respect to pump propagation direction is necessary to design a long haul OFCS incorporated with hybrid EDFA / DRA.

This paper focuses on the analysis of pump propagation direction in DRA using the numerical simulation of DRA mathematical model. This paper is organized as follows. Section II describes the pumping schemes of DRA followed by the DRA mathematical model in section III. Section IV presents the numerical simulation of the DRA mathematical model. Section V investigates the effects of pump propagation direction in DRA using the numerical simulation. This paper concludes with a summary in section VI.

II. DRA PUMPING SCHEMES

There are two pumping schemes to produce DRA in long haul OFCS incorporated with hybrid EDFA / DRA. They are co-propagating and counter-propagating pumping scheme as shown in Fig. 1. Referring to the Fig. 1(a), both the Raman pump and signal light propagates towards the same direction from the transmitter to the receiver. This is known as co-propagating pumping scheme. In case of counter-propagating pumping scheme, Raman pump light is provided from the receiver side and signal light propagates from the transmitter to the receiver as shown in Fig. 1(b).

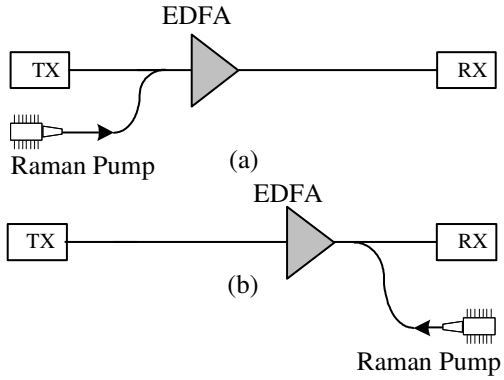

Figure 1. Two pumping schemes of DRA: co-propagating (Fig. 1(a)) and counter-propagating (Fig. 1(b)) pumping schemes.

III. MATHEMATICAL MODEL OF DRA

For the purpose of numerical modeling, pump power level is considered high enough to produce stimulated Raman scattering (SRS). During SRS the interaction between the co-propagating pump power (P_P^+) and signal power (P_S) as well as counter propagating pump power (P_P^-) and P_S are governed by the following set of coupled equations, derived from the Maxwell's equations [6, 9]:

$$\frac{dP_S}{dZ} = \frac{g_R}{A_{eff}} P_P^{\pm} P_S - \alpha_S P_S \tag{1}$$

$$\frac{dP_P^+}{dZ} = -\frac{\omega_P}{\omega_S} P_P^+ P_S - \alpha_P P_P^+ \quad (2)$$

$$\frac{dP_P^-}{dZ} = \frac{\omega_P}{\omega_S} P_P^- P_S + \alpha_P P_P^- \quad (3)$$

Where Z is the co-ordinate of the signal propagation direction, A_{eff} is the effective area of the fiber, g_R is the Raman gain coefficient as well as α_S and α_P account for fiber losses at the signal frequency (ω_S) and pump frequency (ω_P) respectively. The pump depletion must be included for a complete description of SRS but it can be neglected for the purpose of estimating the Raman threshold [6]. So, if we neglect the first term on the right hand side of equation (2) and (3), which is responsible for pump depletion, then equation (2) and (3) are readily solved to give:

$$P_P^+(Z) = P_{P_in}^+ e^{-\alpha_P L(Z)} \quad (4)$$

$$P_P^-(Z) = P_{P_in}^- e^{-\alpha_P L(Z)} \quad (5)$$

Where $P_{P_in}^+$ and $P_{P_in}^+$ is the co-propagating and counter propagating input pump power respectively as well as *L(Z)* is the distance between the pump source and *Z* co-ordinate of the transmission fiber. Now from equation (1) with the help of equation (4) and (5), we have,

$$\frac{dP_S}{dZ} = \frac{g_R}{A_{eff}} P_S P_{P_in}^{\pm} e^{(-\alpha_P Z)} - \alpha_S P_S \quad (6)$$

By solving equation (6) we have,

$$P_S(Z) = P_{S_in\ (Z)}\, e^{\frac{g_R P_{P_in}^{\pm}}{A_{eff}(-\alpha_P)}(e^{(-\alpha_P Z)}-1)-\alpha_S Z} \quad (7)$$

Where, $P_{S_in\ (Z)}$ is the input signal power at location *Z* of the transmission fiber. Now we can calculate the input signal power of the receiver from equation (7) as

$$P_S(L) = P_{S_in\ (0)} e^{\frac{g_R P_{P_in}^{\pm} L_{eff}}{A_{eff}} - \alpha_S L} \quad (8)$$

Where $L_{eff} = \frac{1}{\alpha_P}[1 - e^{-\alpha_P L}]$ (9)

Where, $P_{S_in\ (0)}$ is the signal power enters at the input of the transmission fiber, L is total transmission length, L_{eff} is the effective length of the transmission fiber within which signal is amplified due to the DRA. The total gain (G) due to the SRS in the transmission fiber is calculated from equation (8) as:

$$G = (P_{S_in(0)} e^{\frac{g_R P_{P_in}^{\pm} L_{eff}}{A_{eff}} - \alpha_S L} / P_{S_in(0)})$$

$$= e^{\frac{g_R P_{P_in}^{\pm} L_{eff}}{A_{eff}} - \alpha_S L} \quad (10)$$

Total signal attenuation in the transmission fiber is: $e^{-\alpha_S L}$
So, the net Raman gain is calculated as:

$$G_R = e^{\frac{g_R P_{P_in}^{\pm} L_{eff}}{A_{eff}} - \alpha_S L} * e^{-\alpha_S L}$$

$$= e^{\frac{g_R P_{P_in}^{\pm} L_{eff}}{A_{eff}}} \quad (11)$$

IV. NUMERICAL SIMULATION OF DRA MATHEMATICAL MODEL

Effective length of the DRA is calculated from the equation (9). Gain due to the DRA is calculated by iterative process using equation (4)-(5) and (11). Calculation of the Raman gain is started from the beginning of the effective length. Raman gain of the 1st meter of effective length is calculated according to the equation (11) by the input pump power at the beginning of effective length. The input pump power at the beginning of 2nd meter is then calculated from equation (4)-(5). Then the Raman gain of the 2nd meter of effective length is calculated according to the equation (11) by the input pump power at the beginning of 2nd meter. This process continues iteratively up to the end of the effective length. Total Raman gain is achieved by the cumulative gain through the whole effective length. The single mode fiber (SMF) parameters used to simulate the mathematical model is shown in Table 1. The typical values of A_{eff} , α_S and α_P are used for the purpose of numerical simulation as well as the value g_R is used according to the wavelength difference between pump and signal power.

TABLE I
INTRINSIC PARAMETERS OF SMF USED IN SIMULATION

L = 50 km.	$P^{-}_{P_in}$ = 200 mW.
$P_{S_in(0)}$ = 0.1 mW.	$P^{+}_{P_in}$ = 200 mW.
A_{eff} = 70 X 10^{-12} cm^2.	g_R = 3.9 X10^{-4} m/W.
λ_S = 1550 nm.	λ_P =1480 nm.
α_S = 0.20 dB/Km.	α_P = 0.24 dB/Km.

V. ANALYSIS OF PUMP PROPAGATION DIRECTION

In order to help the designers to calculate the power budget of a long haul OFCS incorporated with a DRA, a detailed analysis is carried out in this section using the numerical simulation of the DRA mathematical model. The comparison between co- and counter-pumped Raman gain at 1550 nm signal wavelength as a function of 1480 nm pump power using 50 km long transmission fiber for various signal power is shown in Fig. 2. From this Figure, 200 mW pump power shows a signal gain of 2.21 dB for 1 mW signal power, 4.49 dB for 0.1 mW signal power and 5.65 dB for 10 nW signal power using counter-propagating pump power as well as 0.44 dB for 1 mW signal power, 4.37 dB for 0.1 mW signal power and 5.43 dB for 10 nW signal power using co-propagating pump power. On the other hand, 2 watt pump power shows a signal gain of 9.95 dB for 1 mW signal power, 18.65 dB for 0.1 mW signal power and 50.53 dB for 10 nW signal power using counter-propagating pump power as well as 3.18 dB for 1 mW signal power, 16.33 dB for 0.1 mW signal power and 48.54 dB for 10 nW signal power using co-propagating pump power. According to the results in Fig. 2, counter-propagating pump power provides a higher gain than co-propagating pump power. This is because, signal power at the beginning of the effective length of co-propagating pumping scheme is higher than the signal power at the beginning of the effective length of counter-propagating pumping scheme and this higher signal power depletes the pump power at a higher rate. As a result, the signal gain is lower for the co-propagating pumping scheme.

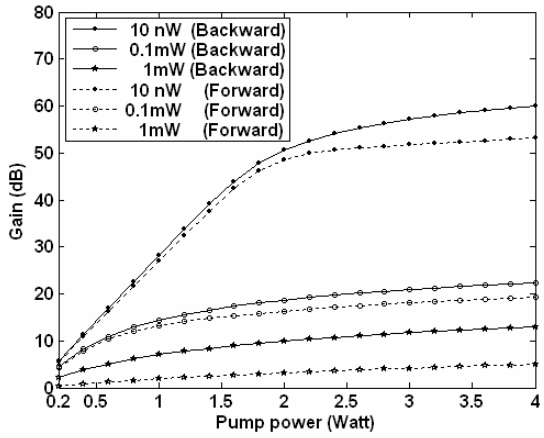

Figure 2. Comparison between Raman gain with respect to co- and counter-propagating pump power at 1550 nm signal wavelength as a function of 1480 nm pump power using 50 km long transmission fiber for various signal power.

The signal propagation characteristics at 1550 nm with (bold line) and without (dotted line) Raman effect as a function of position along a 50 km long transmission fiber using 200 mW pump power and co-propagating pumping scheme is shown in Fig. 3. The signal power at the input of the transmission fiber is 0.1 mW (-10 dBm). The input signal is amplified in the beginning 17.25 km effective length of the transmission fiber and after the effective length the signal power attenuates linearly due to the absorption of signal in the transmission fiber. Without Raman effect the signal power at the end of the transmission fiber is 0.010 mW (-20 dBm) but due to the Raman amplification signal power at the end of the transmission fiber is 0.018 mW (-17.26 dBm), which indicates a net Raman gain of 2.74 dB.

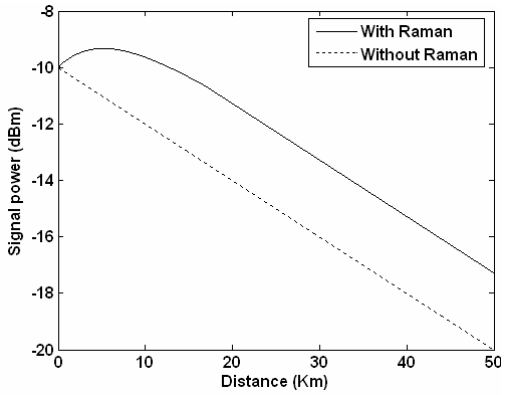

Figure 3. Signal power with and without Raman gain as a function of position along a 50 km long transmission fiber using co-propagating pump power.

Fig. 4 shows the signal propagation characteristics at 1550 nm with (bold line) and without (dotted line) Raman effect as a function of position along a 50 km long transmission fiber using 200 mW pump power and counter-propagating pumping scheme.

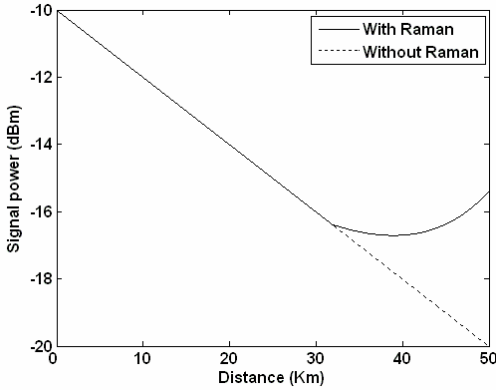

Figure 4. Signal power with and without Raman gain as a function of position along a 50 km long transmission fiber using counter-propagating pump power.

The input signal power at the input of the transmission fiber is 0.1 mW (-10 dBm). The input signal power attenuates in the beginning 32.75 km of the transmission fiber due to the absorption of signal in the fiber as well as the signal power amplifies due to the Raman effect in the last 17.25 km of the transmission length. Without Raman effect the signal power at

the end of the transmission fiber is 0.010 mW (-20 dBm) but due to the Raman amplification signal power at the end of the transmission fiber is 0.029 mW (-15.40 dBm), which indicates a net Raman gain of 4.60 dB. The analysis of co- and counter-propagating pumping scheme shows that the counter-propagating pumping scheme provides more amplification than the co-propagating pumping scheme for the same amount of pump power which justifies the findings in Fig. 2.

VI. CONCLUSION

DRA pumping schemes for long haul OFCS and the mathematical model of DRA to calculate the gain due to DRA are described. The approach to numerically solve the DRA mathematical model is investigated. The effects of pump propagation direction in DRA are analyzed using numerical simulation of the mathematical model. Signal amplification and signal propagation characteristics with and without Raman gain are investigated using co- and counter-propagating pumping scheme. These findings can be used to analyze the power budget improvement with respect to pump propagation direction, which is used to design a remotely pumped long haul OFCS incorporated with hybrid EDFA / DRA.

***Abstract*- We present the comparison of CDMA MAC protocol with and without beat noise by using 2-D optical CDMA MAC protocol over WDM networks. We use the asymmetric prime-hop sequence code. Moreover, we analyse the effect of the number of available wavelengths in terms of average number of attempted to transmissions per time slot (offered load), and beat noise is considered. The presented numerical results based on the throughput and delay time versus the offered load. We divide into two parts. The first one, we consider the effect of the number of available wavelengths. Another is the effect of with and without beat noise in the 2-D OCDMA over WDM systems.**

I. INTRODUCTION

In the middle of 80's, OCDMA (Optical code division multiple access) has been widely developed as high-optical communication network systems, where encoding and decoding are all performed in optical domain [1-2]. The advantageous function of the optical CDMA is the fact that it lets each user to access the network asynchronously and simultaneously without strict wavelength controls and timing synchronizations, but other systems needed such as in the case of wavelength division multiple access (WDMA) and time division multiple access (TDMA), respectively. In addition, optical CDMA local area networks allow shared access to a broadcast medium. However, the OCDMA has interference occur when the number of codeword are assigned increasing, call multiple access interference (MAI).

Especially, OCDMA will be operated on Ethernet passive optical networks (EPON) because of the EPON architecture is the key function in local area network (LAN). Moreover, it also can be upgradeable to Gigabit Ethernet and 10 Gigabit Ethernet, respectively, and in the future; when OCDMA are used on EPON, the capacity and bandwidth will increase [3-4].

In addition, many papers propose and focus on the physical layer of CDMA network [1-2, 6-7]; however, few papers have considered the MAC protocol with beat noise. Therefore, this article, we present the comparison of OCDMA MAC protocol with and without beat noise by using 2-D optical CDMA over WDM networks and asymmetric prime-hop sequence code is used. The family of asymmetric prime-hop sequence code has $p_s(p_h-1)$ of length p_s^2 and each code had Hamming weight p_s (prime number). At the source, tunable laser (or laser arrays) and tunable fiber delay-lines used to select the pulse wavelength and time position. Therefore, passive network of matched delay lines and corresponding optical filters required at the receiver.

This paper is organized as follows. In section II, the network model description is discussed, and the performance of 2-D asymmetric prime-hop sequence optical CDMA code over WDM networks is presented. In section III, the numerical results of the performance are reported with based on throughput and delay time. Finally, we give concluding in section IV.

II. PERFORMANCE ANALYSIS

A. Network Model

In figure 1, the network consists of a basic OCDMA, which the users are assigned with different optical code and share common transmission medium. The coding can be performed on to 1-dimension (1-D) either in time domain, or frequency domain, or performed on to 2-dimension (2-D) in both frequency and time domains simultaneously.

However, we focus on OCDMA over WDM PON networks. On each WDM grid $\lambda_n (n = 1,...,N)$, not a single channel, and M simultaneous users can be accommodated by individually assigning each user with a different code. Therefore, the total capacity of OCDMA over WDM PON becomes N times when compare with WDM PON. Moreover, we use 2-D coding, and the signals are transmitted over WDM channels [3-4]. The OCDMA over WDM PON is presented in figure 1.

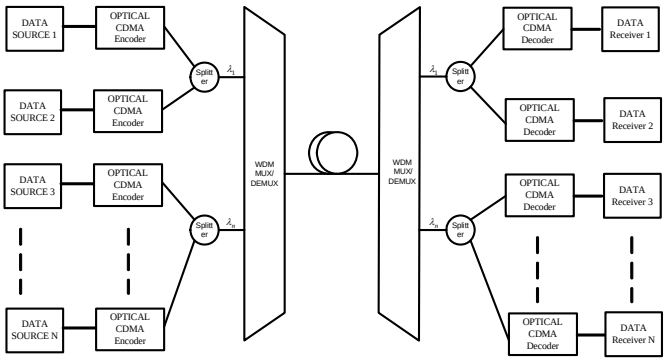

Figure 1. Optical CDMA network over WDM.

B. 2- D Optical CDMA Code

This article, we limit our analysis to OCDMA network that we use the asymmetric prime-hop sequence described by Tancevski et al. [5]. The advantages of 2-D codes in this family have low cross-correlations, nonexistent

autocorrelation side lobes and large cardinalities. Hence, the bits error rate of asymmetrical prime-hop sequence with beat noise is given by [5]

$$P_{error}(m)=\sum_{i=1}^{m-1}\binom{m-1}{i}2^{-(m-1)}\sum_{j=1}^{i}\binom{i}{j}\left(\frac{\langle\mu\lambda\rangle}{p_s^2}\right)^j\cdot \left(1-\frac{\langle\mu\lambda\rangle}{P_s^2}\right)^{i-j}\frac{1}{2}\left\{Q\left(\frac{p_sP_dD-jP_c}{\sqrt{2P_cP_c\binom{j}{2}\frac{1}{p_s}}}\right)+ Q\left(\frac{p_sP_d+jP_c+p_sP_dD}{\sqrt{2jP_dP_c+2P_cP_c\binom{j}{2}\frac{1}{p_s}}}\right)\right\} \quad (1)$$

Where $Q(x)$ is Q function, given by

$$Q(x)=\frac{1}{2\pi}\int_x^{\infty}\exp(-y^2/2)dy \quad (2)$$

and

$$\langle\mu\lambda\rangle=\frac{1}{\binom{p_h}{p_s}}\left[\binom{p_h-1}{p_s-1}\frac{(p_s-1)(p_s-2)+(p_h-2)}{p_h-2}+\binom{p_h-1}{p_s}\frac{p_s(p_s-1)}{p_h-2}\right] \quad (3)$$

is the average number of wavelengths common to any pairs of asymmetrical prime-hop sequences.
Hence,

p_s (prime code) is the number of pulses per wavelengths

p_h (prime code) is the number of available wavelengths

P_c is optical power of crosstalk pulse

P_d is optical power of bits data pulse

D is the threshold level

However, when consider the limiting case of negligible beat noise, i.e., all noise sources are neglected. This means that SNR is infinite [7]. Therefore, for positive signals of the term of Q function is zero in (1), and when the signals is negative Q function is 1 (in the case of when bit "0" is transmitted and j becomes greater than the threshold, we got $\theta = p_sP_dD$). We give the total probability of error when neglected beat noise, is [5]

$$P_{error}(m)=\frac{1}{2}\sum_{i=1}^{m-1}\binom{m-1}{i}2^{-(m-1)}\sum_{j=\theta}^{i}\binom{i}{j}\cdot \left(\frac{\langle\mu\lambda\rangle}{p_s^2}\right)^j\left(1-\frac{\langle\mu\lambda\rangle}{p_s^2}\right)^{i-j} \quad (4)$$

Additionally, the asymmetrical prime-hop sequences have a length in a time domain of p_s^2 chips and can be supported a maximum of $p_s(p_h-1)$ simultaneous users.

C. MAC protocol Analysis

We use the synchronous and random-access protocol for scheduling packets which is the length of a slot corresponds to L bits. A number of packets from many sources can be transmitted over the optical fiber in a single slot.

Moreover, some of the packets arrive at the receiver with bit errors because multiple-access interference (MAI) occurred by m simultaneous users increasing. We let $P_{error}(m)$ be the probability of a bit error when there are m simultaneous transmissions on the channel. The characteristics of $P_{error}(m)$ will depend upon the size, weight and family of the OCDMA code under consideration. Therefore, the probability of receiving a packet will occur without errors when m simultaneous transmissions on the channel are given by [7].

$$P_{correct}(m)=[1-P_{error}(m)]^L \quad (5)$$

and the condition of receiving a correct packet is

$$P_{correct}(m)=\begin{cases}[1-P_{error}(m)]^L, & 0\le m\le p_s(p_h-1)\\ 0, & p_s(p_h-1)\le m\le\infty\end{cases} \quad (6)$$

However, with suitable error-detection capability, at the receiver can detect and determine if one or more errors have occurred in the packets. For simplicity, the overhead required of error-detection is not considered. In a broadcast network, the sender can independently determine the success or failure of the transmission and queue the packet for retransmission after a random delay in the buffer.

From according above, we let M be a random variable that represents the number of simultaneous in a time slot. Therefore, the conditional distribution of the number of successfully received packets S is

$$P[S=s\mid M=m]=\binom{m}{s}P_{corect}^S(m)[1-P_{correct}(m)]^{m-s} \quad (7)$$

The steady-state throughput can be shown in equation (8).

$$\beta=E[S]=E[E[S\mid M]]=\sum_{m=1}^{\infty}mP_{correct}(m)f_m(m) \quad (8)$$

Where $f_m(m)$ is the steady-state probability distribution of composite arrivals, which include new and retransmission packets in queue. In this article, we assume that the composite arrival distribution is Poisson arrival with rate λ

$$f_M(m) = \frac{(\lambda T)^m}{m!} e^{-\lambda T} \tag{9}$$

Here, T is the temporal length of the packet.

Additionally, the choice of arrival distribution corresponds to an infinite user population. Giving $\gamma \equiv \lambda T$ to be the offered load (average number of attempted transmissions per time slot), so the throughput becomes

$$\beta = e^{-\gamma} \sum_{m=1}^{\infty} m P_{correct}(m) \frac{\gamma^m}{m!} \tag{10}$$

Then, the delay measured in the average number of retransmissions per packet, given by [6]

$$d = \frac{\gamma}{\beta - 1} \tag{11}$$

III. Numerical Results

In this section, we present the numerical results of OCDMA over WDM systems with and without beat noise. The asymmetric prime-hop code used with OCDMA chip-rates p_s^2, packets lengths set to $L = 1024$ bits and set $p_s = 13$. The results are shown two parts. The first one, we consider the effect of the number of available wavelengths (p_h), figure 2 and 3. Another is the effect of the comparison of OCDMA MAC protocol with and without beat noise when using the 2-D OCDMA over WDM systems, figure 4 and 5. However, it is based on throughput (β) and delay time (d) versus offered load (G).

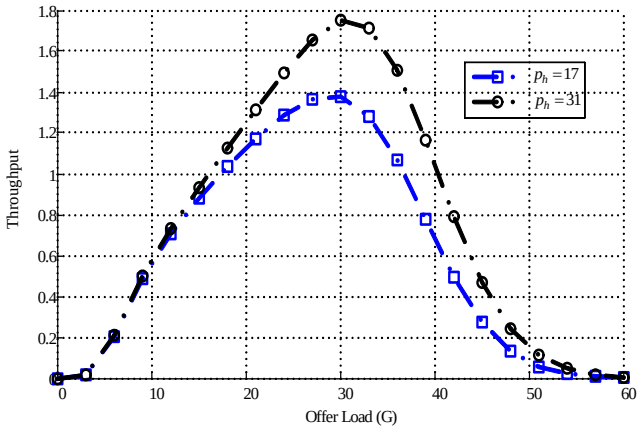

Figure 2. Throughput versus offered load with $p_h = 17$, 31

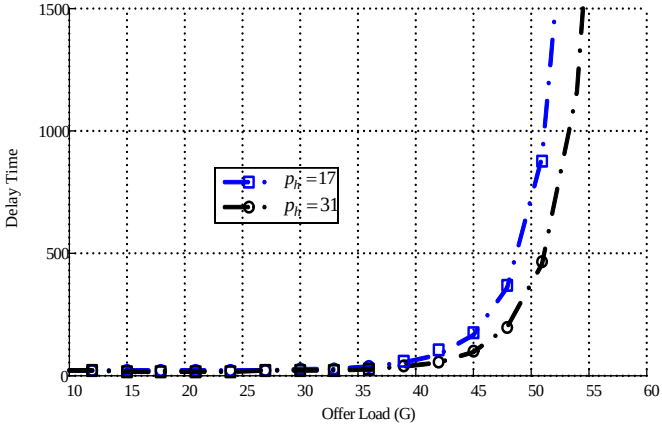

Figure 3. Delay time versus offered load with $p_h = 17$, 31

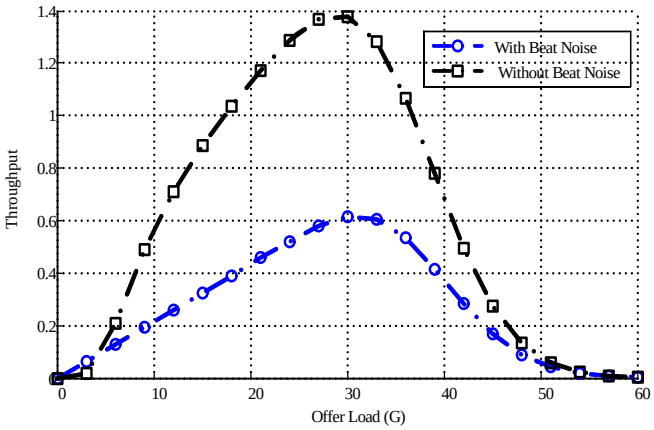

Figure 4. Throughput versus offered load with and without beat noise

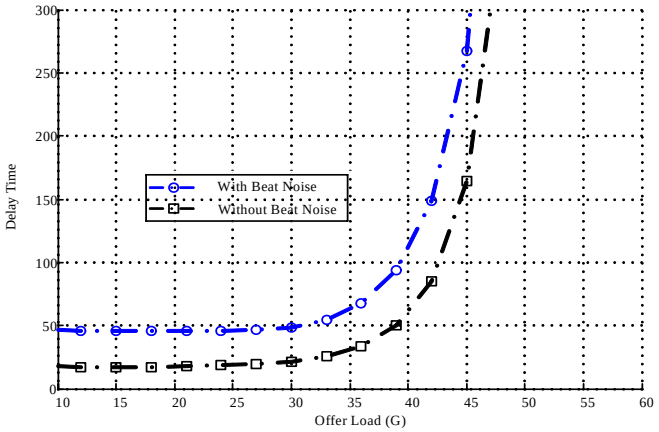

Figure 5. Delay time versus offered load with and without beat noise

Figure 2 compares the throughput versus offered load of OCDMA systems occurred without beat noise with $p_s = 13$, $p_h = 17$ and $p_h = 31$ (the available wavelengths), respectively.

We can see that the curves of throughput are parallel, but when a number of available wavelengths (p_h) increased, throughput increases.

Figure 3 plots the delay time as a function of the offered load for difference the number of available wavelengths (p_h) of OCDMA systems without beat noise. We set, again, the $p_s = 13$, $p_h = 17$ and $p_h = 31$, respectively. It is shown that the delay time start to increase at the offered load around 35-40 and then increases exponentially with the offered load. Additionally, the delay time decrease when the number of available wavelengths (p_h) increased.

Figure 4 shows the throughput with and without the beat noise versus offered load of OCDMA systems with $p_s = 13$ and the available wavelengths $p_h = 17$, respectively. It can be seen that the curves of throughput of without beat noise higher than the throughput with beat noise. Moreover, it clears that beat noise strongly affects the system performance and decreases the amount of simultaneous users.

Figure 5 plots the delay time as a function of the offered load for difference the number of available wavelengths (p_h) with and without beat noise. It is shown that the delay time start to increase at the offered load around 30-35 and then increases exponentially with the offered load. These means that beat noise has more effect in OCDMA system. Therefore, the beat noise is a very big problem and also is a big challenge how to reduce the beat noise effect in OCDMA systems.

IV. CONCLUSION

We propose performance evaluation of CDMA MAC protocol with and without beat noise by using 2-D optical CDMA over WDM networks. We use the asymmetric prime-hop sequence code. Moreover, we observe the effects of a number of available wavelengths in terms of average number of attempting to transmit per time slot (offered load), and also beat noise in system is considered. The presented numerical results based on the throughput and delay time versus the offered load. The results clear that the beat noise and prime code number has more effect in OCDMA system. Therefore, the beat noise is a very big problem and challenges to researcher who would like to reduce the beat noise effect in OCDMA systems.

***Abstract*- The resonances of spherical resonator, with perfectly conducting wall and filled with a homogeneous isotropic chiral medium, is studied, using vector spherical wavefunctions. The aim of this work is to rewrite the equation in terms of vector spherical wavefunction and derive the characteristic equation for the problem when the relative chirality is one. Resonant frequencies of the first few modes for *n* = 1 and *n* = 2 are reported and discussed. These modes are hybrid modes. They are classed as either hybrid electric (HE) modes or hybrid magnetic (HM) modes.**

I. INTRODUCTION

Dielectric filled cavity resonators and dielectric resonators have been studied extensively because of their used in filters and antennas [1]–[4]. However, their used required a good knowledge of their resonant frequencies and *Q* factors. The resonances of a dielectric filled cavity resonator [5]–[6] and a dielectric sphere [7]–[9] have been presented in the past. The electromagnetic resonances and *Q* factor of a chiral sphere has been studied extensively in [10]. The resonances of spherical resonator, with perfectly conducting wall and filled with a homogeneous isotropic chiral medium, has been studied in [11]–[12]. The characteristic equations given in [11]–[12] does not work when the chirality approached the maximum limit given in [13] or the relative chirality defined in [10] approaches one and is invalid when it exactly equals to one. This paper is an extension of the work in [11]. In this paper, the characteristic equation of the problem in Fig. 1 is rewritten using the constitutive relation given in [10]. The detailed derivation of the characteristic equation is given for the case when the relative chirality is one. The characteristic equation is derived by forming solutions for the electromagnetic field inside the spherical resonator, which is completely filled with a chiral medium, in terms of the spherical vectorfunctions and enforcing the boundary condition on the tangential components of the electric filed on the surface of the sphere. The characteristic equation is solved by using the search function *fminsearch* provided by MATLAB [14].

II. THE SPHERICAL SOLUTIONS FOR A CHIRAL MEDIUM

The constitutive relations for a chiral medium are expressed as

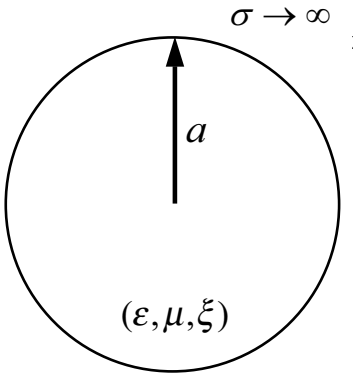

Figure 1. Geometry of the problem of resonances of a chiral filled conducting spherical cavity.

$$\mathbf{D} = \varepsilon \mathbf{E} - j\xi \mathbf{H} \tag{1}$$

$$\mathbf{B} = \mu \mathbf{H} + j\xi \mathbf{E}. \tag{2}$$

The electromagnetic field in a chiral medium can be decomposed in two parts, the right-handed wave ($\mathbf{E}_+$, $\mathbf{H}_+$) and the left-handed wave ($\mathbf{E}_-$, $\mathbf{H}_-$) [10]. The total electromagnetic field ($\mathbf{E}$, $\mathbf{H}$) can be written as

$$\mathbf{E} = \mathbf{E}_+ + \mathbf{E}_- \tag{3}$$

$$\mathbf{H} = \mathbf{H}_+ + \mathbf{H}_-. \tag{4}$$

Each of theses two wavefields ($\mathbf{E}_+$, $\mathbf{H}_+$) and ($\mathbf{E}_-$, $\mathbf{H}_-$) sees the chiral medium as an equivalent isotropic medium with respective medium parameters (μ_+, ε_+) and (μ_-, ε_-). The equivalent parameters ($\varepsilon_\pm$, $\mu_\pm$) and wave impedances $\eta_\pm$ are give as

$$\varepsilon_\pm = \varepsilon(1 \pm \xi_r) \tag{5}$$

$$\mu_\pm = \mu(1 \pm \xi_r) \tag{6}$$

$$\mu_\pm = \sqrt{\frac{\mu_\pm}{\varepsilon_\pm}} = \sqrt{\frac{\mu}{\varepsilon}} = \eta = \eta_0 \sqrt{\frac{\mu_r}{\varepsilon_r}} \tag{7}$$

where $\mu = \mu_o \mu_r$, $\varepsilon = \varepsilon_o \varepsilon_r$, and $\eta_o = \sqrt{\mu_o / \varepsilon_o}$ is the free-space wave impedance. The relative chirality ξ_r is defined by

$$\xi_r = \frac{\xi}{\sqrt{\mu\varepsilon}}. \tag{8}$$

For equivalent media, the wavenumber can be express in terms of free-space wavenumber as

$$k_\pm = \omega\sqrt{\mu_\pm \varepsilon_\pm} = k_o \sqrt{\mu_r \varepsilon_r}(1 \pm \xi_r) = k(1 \pm \xi_r). \tag{9}$$

These wavenumber are non-negative numbers when $-1 \le \xi_r \le 1$. In this paper, we assume that ξ_r is a positive number.

III. Fields Inside The Spherical Resonator

The resonant electromagnetic field inside a chiral filled conducting spherical cavity can be expressed as

$$\mathbf{E} = \sum_{m,n} \{ jc_{\{e,o\}mn}(\mathbf{N}^{(1)}_{\{e,o\}mn}(k_+ r) + \mathbf{M}^{(1)}_{\{e,o\}}(k_+ r)) + d_{\{e,o\}mn}(\mathbf{N}^{(1)}_{\{e,o\}mn}(k_- r) - \mathbf{M}^{(1)}_{\{e,o\}mn}(k_- r))\} \tag{10}$$

$$\mathbf{H} = -\frac{1}{\eta}\sum_{m,n} \{ c_{\{e,o\}mn}(\mathbf{N}^{(1)}_{\{e,o\}mn}(k_+ r) + \mathbf{M}^{(1)}_{\{e,o\}}(k_+ r)) + jd_{\{e,o\}mn}(\mathbf{N}^{(1)}_{\{e,o\}mn}(k_- r) - \mathbf{M}^{(1)}_{\{e,o\}mn}(k_- r))\} \tag{11}$$

where $\mathbf{M}^{(1)}_{\{e,o\}mn}(k_\pm r)$ and $\mathbf{N}^{(1)}_{\{e,o\}mn}(k_\pm r)$ are the vector spherical wavefunctions given in [10]. The subscript *o* indicates that the fields is odd with respect to ϕ and the subscript *e* indicates that the fields is even with respect to ϕ. $c_{\{e,o\}mn}$ and $d_{\{e,o\}mn}$ are the unknown expansion coefficients. The expansion coefficients can be obtained using the boundary condition at $r = a$. The tangential components of the electric field must vanish at $r = a$. Therefore

$$\mathbf{a}_r \times \mathbf{E} = 0 \tag{12}$$

where $\mathbf{a}_r$ is the unit radial vector. Using the expression for $\mathbf{M}^{(1)}_{\{e,o\}mn}(k_\pm r)$ and $\mathbf{N}^{(1)}_{\{e,o\}mn}(k_\pm r)$ given in [10] and the fact that these vector spherical wavefunctions are orthogonal, (12) can be expanded into two equations as

$$jc_{\{e,o\}mn} A - d_{\{e,o\}mn} B = 0 \tag{13}$$

$$jc_{\{e,o\}mn} C + d_{\{e,o\}mn} D = 0 \tag{14}$$

where

$$A = \frac{\hat{J}_n(k_+ a)}{k_+ a} \tag{15}$$

$$B = \frac{\hat{J}_n(k_- a)}{k_- a} \tag{16}$$

$$C = \frac{\hat{J}'_n(k_+ a)}{k_+ a} \tag{17}$$

$$D = \frac{\hat{J}'_n(k_- a)}{k_- a}. \tag{18}$$

Equations (13)–(14) for both odd and even modes are written in matrix form as

$$[Z][I] = [V] \tag{19}$$

where

$$[Z] = \begin{bmatrix} A & -B \\ C & D \end{bmatrix} \tag{20}$$

$$[I] = \begin{bmatrix} jc_{\{e,o\}mn} \\ d_{\{e,o\}mn} \end{bmatrix} \tag{21}$$

$$[V] = \begin{bmatrix} 0 \\ 0 \end{bmatrix}. \tag{22}$$

Solutions of (19) exist only when [Z] of (20) has zero determinant. This gives the characteristic equation for the chiral filled spherical resonator as

$$AD + BC = 0. \tag{23}$$

Let $ka = x$ be the roots of (23), where *x* is a positive real number and assume that $\xi_r \ne 1$. Substituting (15)–(18) into (23), we obtain

$$\hat{J}_n(x(1+\xi_r))\hat{J}'_n(x(1-\xi_r)) + \hat{J}_n(x(1-\xi_r))\hat{J}'_n(x(1+\xi_r)) = 0. \tag{24}$$

Equation (24) is the characteristic equation given in [11]. It is only valid for $\xi_r \ne 1$. When $\xi_r = 1$, $\hat{J}_n(x(1-\xi_r))$ and $\hat{J}'_n(x(1-\xi_r))$ are zero, nontrivial solutions for (24) do exist. The limiting values of $\hat{J}_n(z)$, and $\hat{J}'_n(z)$ as $|z| \to 0$ are used to derive the characteristic equation when $\xi_r \to 1$. These limiting values are [15, (10.1.4)]

$$\hat{J}_n(z) = \frac{z^{n+1}}{1 \cdot 3 \cdot 5 \ldots (2n+1)} \tag{25}$$

$$\hat{J}_n'(z) = \frac{z^n(n+1)}{1\cdot 3\cdot 5\ldots(2n+1)}. \quad (26)$$

When $\xi_r \to 1$, using (25) and (26), we obtain

$$\frac{\hat{J}_n(x(1-\xi_r))}{\hat{J}_n'(x(1-\xi_r))} = \frac{x(1-\xi_r)}{n+1}. \quad (27)$$

Dividing (24) with $\hat{J}_n'(x(1-\xi_r))$ and using the result from (27), (24) can be rewritten for $\xi_r \to 1$ as

$$\hat{J}_n(x(1+\xi_r)) + \frac{x(1-\xi_r)}{n+1}\hat{J}_n'(x(1+\xi_r)) = 0. \quad (28)$$

Since the characteristic equation is continuous at $\xi_r = 1$, the solutions when $\xi_r \to 1$ are the solutions when $\xi_r = 1$. Letting the relative chirality in (28) equal to one, we obtain the characteristic equation for $\xi_r = 1$ as

$$\hat{J}_n(2x) = 0. \quad (29)$$

After the roots x of the characteristic equation are obtained, the resonant frequency f_r can be computed by

$$f_r = \frac{x}{2\pi a\sqrt{\mu\varepsilon}} \quad (30)$$

IV. Numerical Results and Discussion

We solve for the roots of the characteristic equation numerically by using the function *fminsearch* provided by MATLAB [14]. The roots x of (24) and (29) are plotted in Figs. 1–4 for n = 1 and n = 2 as functions of the relative chirality. The solutions for the first few modes for $\xi_r = 0$ and $\xi_r = 1$ are shown in Table I. For the dielectric filled spherical cavity, TE and TM solutions are computed using (24) with $\xi_r = 0$. Each solution is in excellent agreement with that published in [16] and is used as an initial value for *fminsearch* for each mode. The electromagnetic field in a chiral sphere is always a hybrid mode (HEM mode). The HEM mode which reduces to the TM_{nr} mode when $\xi_r = 0$ is a hybrid magnetic mode called the HM_{nr} mode. The HEM mode which reduces to the TE_{nr} mode when $\xi_r = 0$ is a hybrid electric mode called the HE_{nr} mode. For each mode, x does not change much with respect to the relative chirality. We observe that x for $\xi_r = 1$ is a half of x for one of the TE modes. Equation (29) shows that the field inside the cavity is a TE mode with the wavenumber of 2k.

V. Conclusions

In this paper the resonances of a spherical cavity filled with a chiral medium are presented. This paper was previously presented by [6], but their characteristics equation becomes invalid when $\xi_r = 1$. Here we have reproduced the solution for the problem by using vector spherical function and explicitly discussed the problem when $\xi_r = 1$. This is interesting to see that the wave reduces to a TE mode with the wavenumber of 2k when $\xi_r = 1$.

***Abstract* -This study presents a novel technique for increasing the extent of cancer tissue destruction zone by appropriate placements of microwave antennas at 2.45 GHz. We investigated the temperature distribution during microwave ablation of hepatic cancer treatment. We utilized coaxial multi-slot antenna and open-tip antenna designs in this study by placing in parallel with 10 mm spacing distance. Finite element analyses as well as *in vitro* experiments were performed to compare the resulting temperature distributions. From the results, the "microwave multi-antenna therapy" is able to destroy larger areas of unwanted tissue without having to increase the input power. The maximum lesion destruction zone from this technique was about twice as large as that of the resulting destruction zone created by a single microwave antenna, while the temperature distribution is also more uniformly distributed.**

I. INTRODUCTION

Microwave coagulation Therapy (MCT) is a treatment for hepatic cancer where cancer cells are destroyed by heat. Electromagnetic wave emitted from the distal end of a microwave antenna that is placed in the middle of the tumor will propagate through the surrounding tissue whereby "Joule heating" takes place. Temperature of cancer tissue that absorbs enough electromagnetic energy will then be elevated to 50 °C (a temperature level where cancer cells are destroyed or degraded) or higher. Different microwave antenna designs can result in different characteristics of energy and temperature distributions. Thus, a thorough investigation of various antenna designs is required to improve the efficacy of MCT.

Previous studies have proposed several antenna designs [2] such as different types of monopole antennas, and slot dipole antennas for destruction of unwanted heart tissue. However, further improvement in microwave antenna design is still much needed as the resulting tissue destruction zones from most previous designs were too small to completely destroyed large tumors. A tip-split antenna, formed by using two coaxial-fed slot antennas, was proposed for use at 2.45 GHz [3]. The resulting coagulation region from tip-split antenna was larger as current from both tips propagated into tissue. In addition, [5] utilized two coaxial slot antennas and placed them in a parallel array configuration with varying spacing distances between the two antennas, and input power levels. The experimental results from [5] showed that the maximum coagulation formed had a diameter of 3 cm.

Thus, we performed finite element analyses and *in vitro* experiments using multiple microwave antennas for destruction of hepatic cancer. In both simulation and *in vitro* experiments, we used open-tip and coaxial slot antennas and placed them in various configurations. In addition, we also varied the input power. Then, we determined and compared temperature distributions, as well as the specific absorption rate (SAR) distributions from simulation and *in vitro* experiments.

In Fig. 2 shows geometry and mesh of the array antennas arrangement used in the FEM model. The distance of two antennas was 10 mm .In this study, we used results from finite element method compare with in-vitro experiment results.

II. METHODS

A. SAR (Specific Absorption Rate)

In order to evaluate the heating ability of the antenna, SAR distribution is widely used. The SAR shows the heat generated by the electric field in the tissue, and given by

$$SAR = \frac{\sigma}{\rho}\left|E^2\right| \qquad [W/kg] \qquad (1)$$

Where

σ = Conductivity of tissue [S/m]
ρ = Density of tissue [kg/m^3]
E = Electric field (rms) [V/m]

B. Bio-heat Equation

The bio-heat equation bellow was employed to analyze heat generation from electric energy. We solved the bio-heat equation to obtain the thermal distribution in hepatic cancer tissue.

$$\rho C\frac{\partial T}{\partial t}+\nabla\cdot(-k\nabla T)=\rho_b C_b \omega_b (T_b - T)+Q_{met}+Q_{ext} \qquad (2)$$

where

k = Thermal conductivity [W/m · k]
ρ_b = The blood density [kg/m^3]
C_b = Specific heat of blood [J/ (kg · K)]
ω_b = Blood perfusion [1/s]
Q_{met} = The energy generated by the metabolic process [W/m^3]
Q_{ext} = Spatial heat source [W/m^3]
ρ = Density [kg/m^3]
C = Specific heat [J/(kg · K)]

III. RESULTS

A. Simulation Results

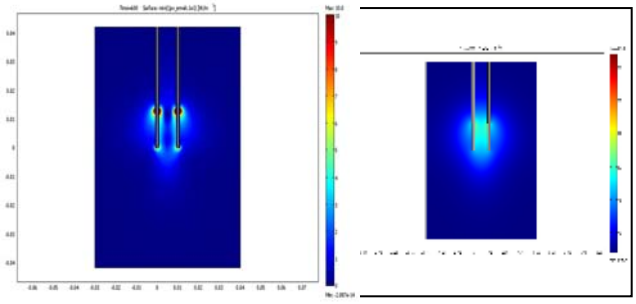

Fig. 3. SAR and temperature distribution of two open-tip antenna array spacing 10 mm

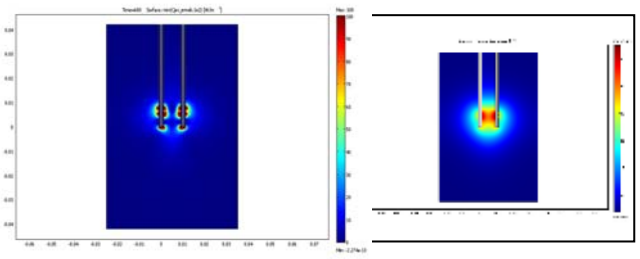

Fig. 4. SAR and temperature distribution of two coaxial-slot antenna array spacing 10 mm

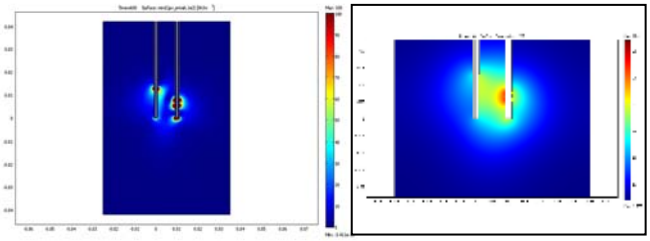

Fig.5. SAR and temperature distribution of open-tip and coaxial-slot antenna array spacing 10 mm

Fig. 3 shows SAR and temperature distributions in liver tissue of two open-tip antennas. From the results, electric field was highest at the tip of two open-tip antennas and the maximum temperature was 51.3 ^{o}C on the center of two antennas arrangement.

Fig. 4 shows SAR and temperature distributions in liver tissue of two coaxial- slot antennas. From the results, electric field was highest at the slot and tip of two coaxial-slot antennas. In this case the maximum temperature was 67 ^{o}C on the center of two antennas arrangement.

Fig. 5 shows SAR and temperature distributions in liver tissue of coaxial- slot and open-tip antennas. From the results, electric field was highest at the slot of coaxial-slot antennas and the tip of open-tip antennas. In this case the maximum temperature was 62 ^{o}C on the slot of coaxial- slot antennas.

B. Experiment Results

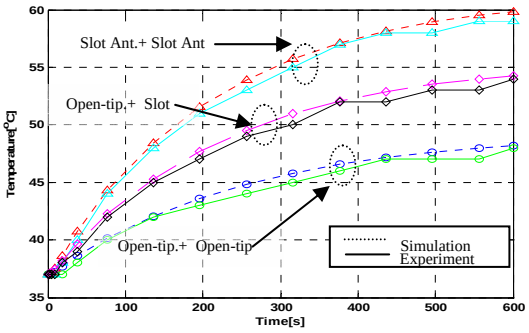

Fig. 6. The change of temperature at different time of three case experiments.

In Fig. 6 shows the change of temperature at different time and Fig.7 shows the lesion of hepatic tissue from *in vitro* experiments. We compare the results from finite element method with experiment results from Bird 54 Thermocouple thermometer. The finite element method results were similar with measured results.

Temperature exchanged of all antennas (Array Coaxial Slot Antenna). Maximum of temperature distributions in tissue and simulation equal 60 ^{o}C when insertion power at both antennas equal to 15 watts , and open-tip antenna have less than equal to 45 ^{o}C , ones equal power insertions to antenna.

IV. CONCLUSION

This paper performs the finite element method for analysis of microwave hepatic ablation (2.45 GHz). We present a new technique for increasing heat for destruction of cancer cells with various alignments of antennas. We aligned two antennas

in array style which has the spacing distance between two antennas equal to 10 mm. The heat occurred in *in vitro* tissue had temperature distribution similar to the result from finite element method. Using two slot antennas resulted in a destructed area of tissue that is larger than that of the open-tip antennas. In addition, lesions generated by multi array antennas were found to be significantly larger than those of single antennas.

Estimation of Heating Performances of a Coaxial-Slot Antenna for Treatment of Colon Carcinoma

Apichon Chintanasinton, Supan Tungjitkusolmun, Pattarapong Phasukkit
Faculty of Engineering
King Mongkut's Institute of Technology Ladkrabang, Thailand 10520
ktsupan@kmitl.ac.th

Abstract **Microwave hyperthermia is one of the modalities for cancer treatment. Microwave ablation is a method where current at frequency of 2.45 GHz is delivered to a small antenna probe in order to elevate surrounding tissue temperature. We have investigated various configurations of coaxial-slot antennas for microwave ablation. A coaxial-slot antenna aiming to generate intracavitary heat for colon carcinoma has been especially developed. This paper use finite element analyses of microwave ablation to predict heating distributions of different antenna designs. Configurations of slot antennas to bent 45° and 90° were considered In addition, we also performed *in vitro* experiments and the results show that coaxial-slot antenna can potentially be used for treatment of colon cancer.**

I. INTRODUCTION

In recent years, various types or medical applications of microwave have widely been investigated and reported. In 1996, Labonté et al [1] used microwave ablation as a treatment for supraventricular arrhythmias. Three monopole geometries were considered: open-tip, dielectric-tip, and metal tip. Subsequently in 2000, Saito [2] presented microwave ablation using coaxial-slot antenna for treatment of liver cancer. In 2003, Chiu [3] presented an expanded slot antenna called "(ETW) expanded tip wire antenna" by increasing the size of the slot for treatment of cardiac arrhythmias. In 2004 Bernardi et al. presented a new antenna called "Cap-Choke antenna" [4] by adding cap and choke at the tip of the antenna thus resulting in a specific heating region around of tip of the antenna which could be use for treatment of cardiac arrhythmias. In addition, Saito et al. [5] used two coaxial-slot antennas for treatment of interstitial cancer. In 2005, Christopher et al. [6] presented a new antenna called "triaxial antenna" and suggested that a larger destruction zone could be achieved in liver tumor. In 2006, Yang et al. [7] presented a floating sleeve antenna for the treatment of hepatic carcinoma, while Saito et al. [8] illustrated a treatment of bile duct carcinoma where the antenna was bent, so it could be inserted into mouth and passed through the esophagus to reach the bile duct.

Presently, more people are suffering from colon carcinoma than in the past, especially in the United States. Using microwave in the treatment of colon carcinoma is a new method for the treatment of colon carcinoma. Traditionally, the treatment of colon carcinoma has been performed using three main methods—the endoscope guided surgery, chemotherapy, and general surgery. In general surgery, patient will lose a lot of blood. In chemotherapy, patients may exhibit allergic reactions. In endoscope guided surgery, only a small incision is needed although this technique can generally cure colon cancer in the primary state.

In this paper, we present the treatment of colon carcinoma using flexible antenna that can be placed near the cancer tissue by inserting it through the anus. In section II, we discuss the method of the simulation and the structure of the antenna that is used in the experiment. In section III, presents the result of the simulation and *in vitro* experiment. The conclusion will be in section V.

II. METHODS

This section describes the physical configuration of the antennas used in this study, as well as principle equations related to analysis of specific absorption ratio and temperature distribution (bio-heat equation). Our microwave antennas operated at a frequency of 2. 45 GHz.

A. Structure of antenna

Figure 1 shows the structure of the coaxial slot antenna used in this study. The basic dimensions of the antennas are also listed in Table 1.

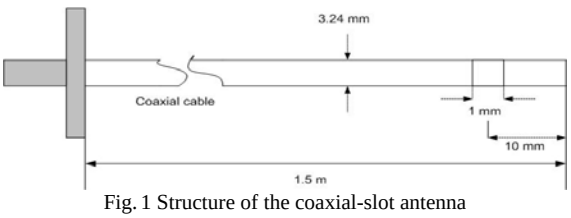

Fig. 1 Structure of the coaxial-slot antenna

B. SAR (Specific Absorption Ratio)

In order to evaluate the heating ability of the antenna, SAR distribution is widely used. The SAR shows the heat generated by the electric filed in the tissue, and given by

$$SAR = \frac{\sigma}{\rho}\left|E^2\right| \qquad [W/kg] \qquad (1)$$

where

σ : conductivity of tissue [S/m]

ρ : is the density of tissue $[kg/m^3]$

E : is the electric field (rms) [V/m]

C. Bioheat Equation:

The bioheat equation below was employed to analyze heat generation from electric energy [9]. We solve the bioheat equation to obtain the thermal distribution in hepatic cancer tissue

$$\rho C\frac{\partial T}{\partial t} + \nabla\cdot(-k\nabla T) = \rho_b C_b \omega_b (T_b - T) + Q_{met} + Q_{ext} \quad (2)$$

Where

k = Thermal conductivity [W/m*k]

ρ_b = Density of blood [kg/m^3]

C_b = Specific heat of blood [J/(kg*K)]

ω_b = Blood perfusion (Perfusion rate) [1/s]

Q_{met} = The energy generated by the metabolic processes [W/m^3]

Q_{ext} = Spatial heat source [W/m^3]

ρ = Density [kg/m^3]

C = Specific heat [J/(kg*K)]

Finite element modeling

In this study, we use a numerical method called finite element modeling (FEM) to simulate heating distribution of different antenna configurations. FEM helps us analyze complex partial differential equation [2] by dividing to domain of interest into many small regions where simpler algebraic equations can be formulated. The structure of a slot antenna is presented, and then we constructed the new type of the antenna. Later on we will construct the real antenna and validate it by experimenting with test tissue, and then we compared the result in the term of the change of temperature in test tissue. We utilized an FEM commercial software software, COMSOL (FEMLAB) *version 3.2b* (Comsol Inc., Burlington, MA).

Due to a tortuous characteristics of the colon, we used a bendable antenna in this study. A shape of a bendable antenna can be manipulated to follow the characteristics of the colon. Thus, we studied the angles (45° and 90°) of the bendable antenna and determined the temperature distribution inside colonic carcinoma tissue. We also performed *in vitro* experiments of microwave ablation using swine colon by inserting the antenna into a swine colon that was filled with air before microwave energy was delivered to the tissue.

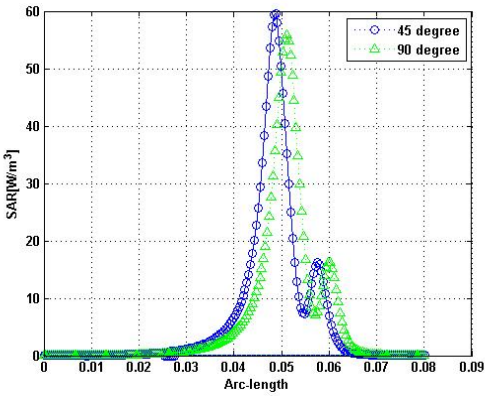

Fig. 4. Comparison SAR of open tip coaxial-slot antenna between 45^o and 90^o

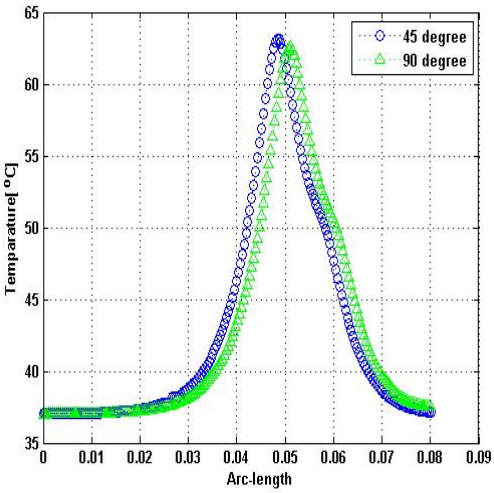

Fig. 5 Comparison of temperatures of open tip coaxial-slot antenna between 45 ^{o} and 90^o

In this section, we show the details of the simulation results. We applied 80 W of power to the antenna at a frequency of 2.45 GHz, and for a duration of 5 min, Fig 2 presents the temperature distribution calculated by FEM of the slot antenna with a bent angle of 45 ^{o}. Fig 3 is the temperature distribution of the slot antenna with a bent angle of 90 ^{o}. Fig 4 shows the comparison of SAR distributions in colon tissue by using the open-tip slot antenna with a 45 ^{o} and 90^o bent angle, measured at 2.5 mm away from the surface of the antenna. From this picture, we notice that SAR profiles have two peak values. The first value is SAR that occurs around the slot and the other peak occurs sat the tip of the antenna. When we compare the SAR at 45^o with 90^o, we found that the SAR at 45^o has slightly higher value than that of 90^o. Fig. 5 shows a comparison of temperature profile of slot antenna with a 45 ^{o} and 90^o bent angle measured at 2.5 mm away from the antenna. We found that the temperature at 45^o rises faster than that of 90^o. Thus, the simulation results illustrate that bendable antennas can potential destroy cancer tissue in colon. Next, we constructed a bendable antenna and performed *in vitro* experiment.

B.In vitro Experimental Results

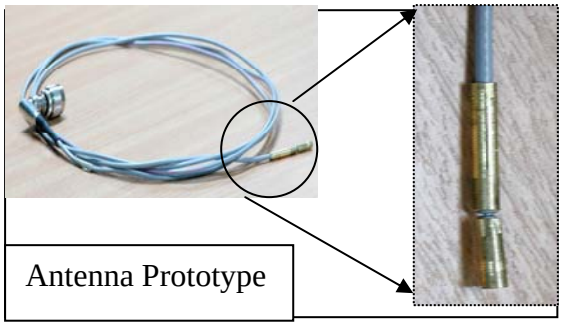

Fig. 6 antenna use in vitro experiment

(a) (b)

Fig. 7. Result of *in vitro* experiment in swine colon

Fig 6 is the prototype antenna that was used in the *in vitro* experiment. The antenna has copper covered at the tip that results in MW getting out around the slot. The fig. 7(a) is outer colon wall and Fig. 7(b) is inner colon wall of swine. The outer colon wall appeared to be destroyed in a greater extent compared to inner colon wall.

V. CONCLUSION

In this paper, we can conclude that a small antenna can be inserted into the colon. We simulated the angle of bendable slot antenna at 45^o and 90^o . The FEM simulation results show that bendable antennas can potential destroy cancer tissue in colon. We then performed in vitro experiments and discovered that a bendable slot antenna was able to destroy tissue along the colon wall. Thus, further studies are needed to improve the efficacy of the bendable slot antenna.

***Abstract*— The size and shape of the reflectors conductor of CPW-fed slot antennas using loading metallic strips and a widened tuning stub (CPW-FSLW) have been observed. By shaping the reflector, noticeable enhancements in both radiation pattern which provides uni-directional and bandwidth can be achieved while maintaining the easy fabrication and installation. Comparing each shapes for the same width reflector, the Λ-and inverted-Λ shape reflectors with a horizontal plate structure have noticeable enhancement both radiation pattern and impedance bandwidth.**

I. INTRODUCTION

In the past few years, printed circuit slot antennas have been extensively investigated. They have the advantages of being able to provide wide impedance bandwidth. Various feeding mechanisms have been proposed in the literature to improve the slot antenna's bandwidth. Many slot antennas fed by microstrip have been reported [1]. Another importance candidate which may complete favorably with microstrip for the many applications is coplanar waveguide (CPW). CPW transmission structures have several attractive features including low radiation, less dispersion, easy integration for MMIC and without the need for vias or holes through the substrate. One of the main issues with CPW-fed slot antennas is to provide an easy impedance matching to the CPW-line. CPW-fed antennas have been increasingly studied in recent years because of their large bandwidth operation. In order to obtain wideband CPW-fed slot antennas, several impedance tuning techniques have been reported in the literature based on a change of slot dimensions in bow-tie slots, a wide rectangular slot, coupling mechanism, dielectric resonator coupling, and other techniques. Their main drawback, however, is essentially a bi-directional radiator, with the back radiation being undesirable, which not only directs half of the power in potentially undesired directions but also increases the sensitivity of the antenna to its surrounding environment and prohibits the placement of such slot antennas on the platforms. Therefore, there are limit its use to a small number of applications.

The antenna should efficiently focus the RF/microwave signal towards the target and collect the back-scattered energy such as the base station antenna of mobile systems and point to point communications. A wideband antenna with uni-directional radiation pattern required for these applications. There are several techniques to reduce the level of back radiation from antennas using reflector[2]-[7]. However, they have a narrow bandwidth. Unfortunately, wideband printed circuit slot antennas with uni-directional radiation pattern have a small literature.

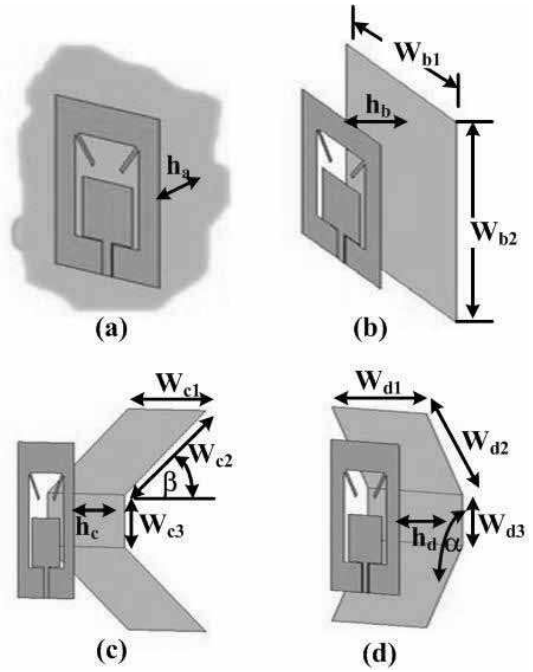

Fig. 1. CPW-fed slot antennas using loading metallic strips and a widened tuning stub above (a) infinite reflector, (b) finite reflector, (c) Λ-shape reflector with a horizontal plate, and (d) inverted-Λ-shape reflector with a horizontal plate.

This paper presents the enhancement of a uni-directional pattern and impedance bandwidth by optimizing the four types of reflector shape including infinite reflector, flat reflector, Λ-shape reflector with a horizontal plate and inverted-Λ-shape reflector with a horizontal plate. The goal in this study is the achievement on a uni-directional all frequencies in operating band and maintain impedance bandwidth equally an antenna without reflector. By shaping the reflector, noticeable

enhancements in both radiation pattern which provides uni-directional and bandwidth can be achieved while maintaining the easy fabrication and installation.

II. CPW-FSLW ABOVE VARIOUS TYPES OF REFLECTORS

In this study, the radiation element is an unbacked CPW-fed slot antennas using loading metallic strips and a widened tuning stub (CPW-FSLW) [8]. It is etched in the ground on the substrate FR-4 (ϵ_r=4.4) with a thickness 1.6 mm. This structure without a reflector radiates a bi-directional pattern and a low gain. Several types of reflector shape are considered in this paper including infinite reflector, finite reflector, Λ and inverted-Λ-shape reflectors with a horizontal plate. By changing the parameters of each reflector such as size of reflector, the distance between radiation element and reflector, and the angle between horizontal plate and the two sides slope reflector of Λ-and inverted-Λ shape reflectors with a horizontal plate are found to affect the impedance bandwidth, resonant frequency and radiation characteristics. These parameters are optimized to enhance the performance antenna. First, the CPW-FSLW located above an infinite reflector plane [Fig. 1(a)] is analyzed. As an example, we considered a CPW-FSLW above an infinite reflector plane with h_a.

An infinite sized reflector is not possible, and small reflector is necessary for base station and point-to-point antennas installation. Thereafter, the same CPW-FSLW antenna is analyzed above a flat finite reflector conductor.The reflector has dimensions of $W_{b1}\times$ W_{b2} and distance between the reflector and radiation element is h_b in Fig. 1(b).

The case for a simple bent conductor ground or corner ground was proposed in [4]. The Λ-shape reflector with the horizontal plate, which is a useful modification of the corner reflector. To reduce the overall dimensions of a large corner reflector the vertex can be cut off and replaced with a horizontal flat reflector ($W_{c1}\times W_{c3}$). The geometry of the proposed broadband CPW-FSLW with a Λ-shape reflector with the horizontal plate as shown in Fig. 1(c). The Λ-shape reflector, having a horizontal flat section dimensions of $W_{c1}\times W_{c3}$, is bent with a bent angle of β. The width of the bent section of the Λ reflector is W_{c2}. The distance between the antenna and the flat section is h_c.

For the last reflector, we modified the shape of the conductor reflector. Instead of a Λ-shape reflector, we took the conductor reflector to have the form of a inverted-Λ-shape reflector Fig. 1(d)]. The geometry of the inverted-Λ-shape reflector with the horizontal plate is shown in Fig. 1(d). The Λ-shape reflector, having a horizontal flat section dimensions of $W_{d1}\times W_{d3}$, is bent with a bent angle of α. The width of the bent section of the inverted-Λ reflector is W_{d2}. The distance between the antenna and the flat section is h_d.

III. CHARACTERISTICS OF ANTENNA BY REFLECTOR CONDUCTOR SHAPES

In order to obtain the uni-directional radiation, a plane reflector is placed parallel to the slot surface on the side of the dielectric substrate. The VSWRs and peak-gains of the

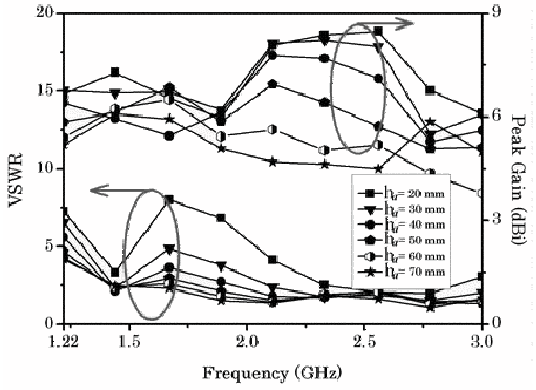

Fig. 2. Computedd VSWR and peak-gain of antenna above infinite reflector with different reflector distances (h_a).

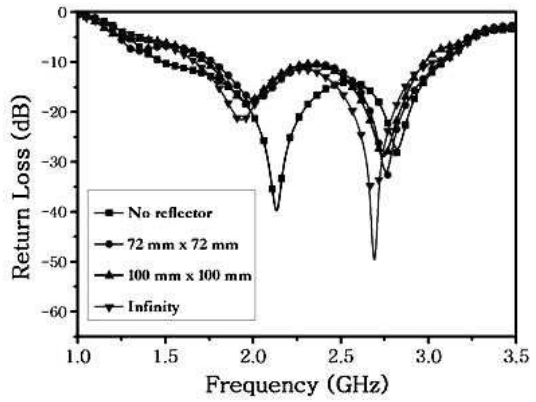

Fig. 3. Return loss of the CPW-FSLW antenna with different sizes of reflector plates where h_a and h_b are 70 mm.

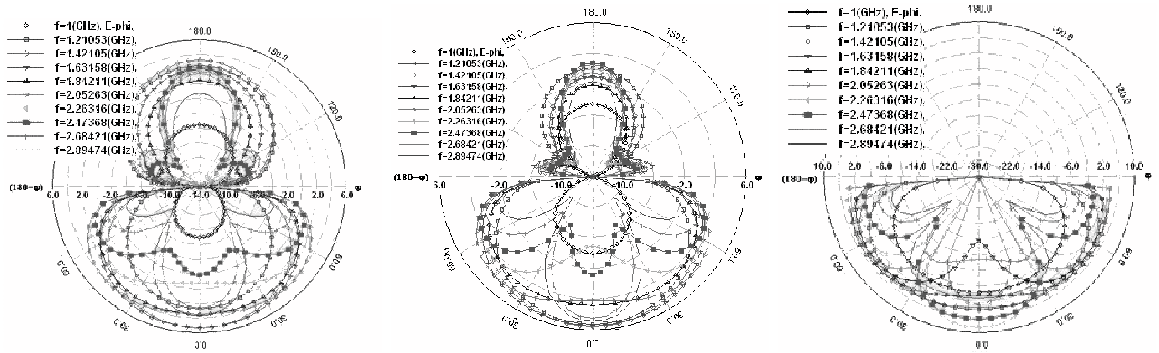
CPW-FSLW antenna above infinite are calculated for different distances between the radiation element and an infinite reflector, as shown in Fig. 2. It can be seen that the matching of the antennas are affected by the distance between the reflector and radiator element. The matching of the antenna above infinite reflector gets worse when the distance between reflector and radiator element (h_a) is increased. Comparisons of the simulated gain obtained by six different distances h_a from 20 mm to 70 mm are also presented in Fig. 2. In these examples, the gain of the antenna increases as the reflector is positioned closer to the radiator element.

The return loss performance of the CPW-FSLW antenna for difference sizes of a finite reflector plate are simulated. IE3D is used to simulate the return loss of all antennas with finite reflector plates. Simulated return loss and directivity results of the CPW-FSLW antenna with different sizes of a reflector plate, including no-reflector, 72 mm$\times$72 mm, 100 mm$\times$100 mm, and infinite size reflector, are shown in Fig. 3. It can be seen that the resonant frequencies will shift lower when the reflector plate size increases. The 10-dB return loss bandwidth is about 1390 MHz for all antennas withwithout reflectors, which is 59% of the center frequency 2.355 GHz. The E-



(a) (b) (c)

Fig. 4. Simulated radiation patterns in E-plane with different sizes reflector (a) 72 mm ×72 mm, (b) 100 mm × 100 mm, and (c) infinite size reflector.

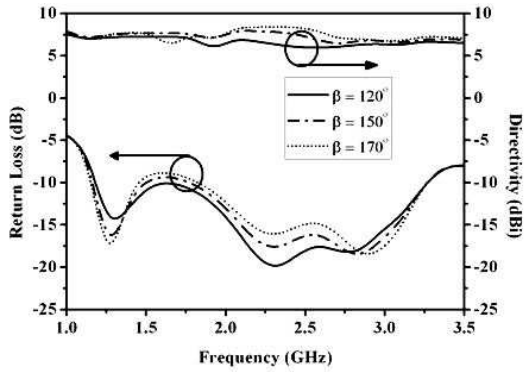


Fig. 5. Simulated return loss and directivity for the proposed antenna as a function β; h_c = 30 mm with W_{c1} = 72 mm, W_{c2} = 40 mm, and W_{c3} = 44 mm.

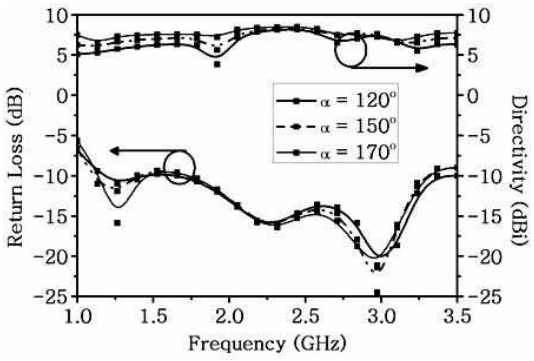

Fig. 6. Simulated return loss and directivity for the antenna as a function α; h_d = 30 mm with W_{d1} = 72 mm, W_{d2} = 40 mm, and W_{d3} = 44 mm.

plane patterns of the CPW-FSLW antenna with different sizes of a reflector plate have been calculated and given in Fig. 4. It can be seen that from Fig.4 that the backside lobe level decreases when the size of the reflector plate increases. The main lobe of both E- plane patterns of the two antennas change slightly when the size of the reflector plate increases from 100×100 mm^2 to infinity. It is obvious that there is no backward radiation in the case of an infinite reflector plate. Further studies are carried out to illustrate the effect of a finite reflector plate on the radiation performance of the CPW-FSLW antenna, as provided in Table I. It can be seen that the bandwidth and the peak gain change slightly when the size of the reflector plate increases from 72 mm ×72 mm size to 100 mm×100 mm. It is also noticed that the front-to-back ratio becomes higher when the size of the reflector increases, as we expected.

The cases for varying the angle β in the proposed design are also studied and the results of the simulated return loss are shown in Fig. 5. Here, the size of the flat reflector is fixed at 72 mm (W_{c1}) × 44 mm (W_{c3}) and the rectangular slope reflectors (W_{c2}×W_{c1}) are 40 mm×72 mm. Table II gives the corresponding simulated data. For obtaining maximum enhanced antenna gain, results indicate that β = 170^o is the optimal angle between the flat section and rectangular slop reflectors with h_c = 30 mm. On the other hand, it is seen that the decreases in β decreases the impedance bandwidth. This behavior is probably because the decrease in β corresponds to the lowering in the effective average substrate thickness in the proposed design, resulting in a smaller impedance bandwidth obtained.

Fig. 6 shows the simulated return loss for the CPW-FSLW above an inveted-Λ reflector with various of α. The flat reflector has dimensions of 44 mm × 72 mm (W_{d3} × W_{d1}) and the rectangular slope reflectors (W_{d2} × W_{d1}) are 40 mm × 72 mm. The distance h_d from the radiator element to the flat reflector is fixed to be 30 mm. The impedance bandwidth is significantly increased by increasing in the bent angle from 120^o to 170^o. The ferformance data of radiation pattern are listed in Table III. When the bent angles are 150^o and 170^o, the antenna's impedance bandwidth reaches about 38%. It can seen that the peak gain change slightly.

The radiation properties are computed for h_c and h_d = 30 mm with the same angle β and α = 170^o are shown in Fig. 7. It is interesting to observe that a uni-directional beam can be achieved all frequency in operating band.

IV. CONCLUSION

This paper presented the investigations of a uni-directional CPW-fed slot antennas using loading metallic strips and a widened tuning stub of four different reflector shapes, namely infinite, finite, inverted-Λ and Λ-shape reflectors. By proper selection of reflector parameters, specially reflector distances, shaped, size, and angle of reflector, a wide impedance bandwidth and uni-directional can be achieved. Both Λ and inverted-Λ reflectors are the achievement on a uni-directional all frequencies in operating band and maintain good impedance bandwidth.

Abstract— **An SoC architecure for media processing is prpoposed, which is based on coarse-grained reconfigurable logic cells. In order to attain high performance at low cost, a series of video decoding processes are executed by efficient cooperation between a host processor and reconfigurable logic cells. Four types of logic cells are introduced in the proposed architecture. Experimental results demonstrate that a multi-standard video decoder can be implemented in the proposed SoC with about 4 times as large hardware cost as a conventional MPEG-2 decoder.**

I. Introduction

For more than a decade, various coarse-grained reconfigurable architectures have been proposed[1] aiming at high performance, high flexibility, and low power consumption. Recently in addition to this, coarse-grained dynamically reconfigurable architectures[2], [3] have been proposed. These architectures support dynamic reconfiguration of each processing element (PE), and can utilize PE more efficiently, which leads to higher performance and flexibility. However, these conventional coarse-grained reconfigurable architectures usually suffer from large hardware cost. On the other hand, an embedded domain-specific reconfigurable architecture, which can provide higher throughput and lower power consumption than ordinary commercial FPGAs, is introduced in [4], [5]. However these reconfigurable architectures offer only limited type of computation, such as ME (Motion Estimation) or DCT (Discrete Cosine Transform), and there still remains considerable disadvantages in terms of area occupation against ASICs.

In this paper, considering trade-off among performance, flexibility, and hardware cost, an embedded domain-specific reconfigurable architecture is devised dedicatedly for media processing.

II. Design Approach

As shown in Fig. 1(a), modern SoC architecture is composed mainly of ASICs, processors, and shared memory. Specifically, an embedded processor performs the process at low computational cost but very complicated, while ASICs perform the process with high computational cost. Generally due to its high computational cost, video processing algorithms are implemented as ASICs to achieve high performance and low power consumption. As a result, several ASICs are employed to support the multi-standard video processing algorithms.

In order to develop an embedded domain-specific reconfigurable architecture (Fig. 1(b)), we address new area-efficient architecture, which is comparable in terms of performance and hardware cost to ASICs.

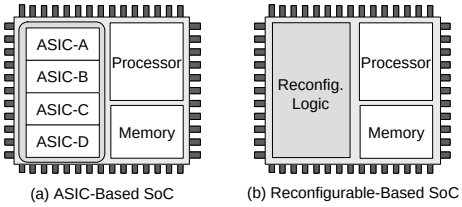

Fig. 1. Reconfigurable-based SoC.

In the course of constructing our domain-specific reconfigurable architecture, the necessary requirements are as follows.

A. Efficient cooperation with a host processor

As exemplified in Fig. 2, there exist data dependences in media processing, such as MPEG-2 decoding. Based on the data dependences and the results of software profiling of media processing, we employ a processor for header analysis, which includes the calculation of moving vector for MC (Motion Compensation). On the other hand, coarse-grained reconfigurable logic is used to execute VLD (Variable Length Decoding), IQ (Inverse Quantization), IDCT (Inverse Discrete Cosine Transform), and MC.

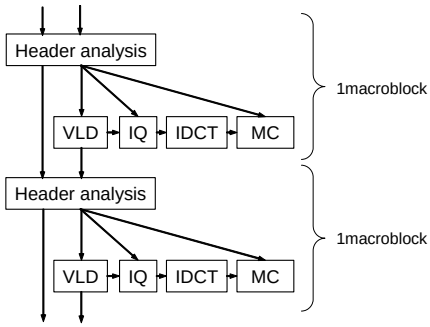

Fig. 2. Data dependency in media processing.

B. Reconfigurable architecture dedicated to media processing

In order to achieve high performance and area efficient implementation of media processing, the reconfigurable architecture must be suitable for performing the distinctive operations of media processing. In this paper, MPEG-2 MP@ML decoder, H.263 Baseline decoder, and MPEG-4 SP decoder are assumed as the target applications.

According to the software profiling results, the granularity, the function, and the ratio of various types of cells are determined. One of the reconfigurable cells is used as a look-up table, a register, and an access scheduler. Another cell is used as a memory, which can keep data during a dynamic reconfiguration. Others are used as computing unit. Basic structure of these heterogeneous cells as well as distinctive interconnect architecture is also introduced.

C. Dynamic reconfigurability

To achieve the decoding process of target applications, the proposed architecture performs VLD, IQ, IDCT, and MC operations in order for each macroblock. Thus dynamic reconfiguration is requested among these operations to raise area efficiency.

D. Reduction of configuration data

Dynamic reconfigurability requires an on-chip configuration memory, which stores multiple configurations. In order to change the configuration within a few cycles, conventional reconfigurable architectures have a configuration memory in each cell, while the size of configuration memory of conventional architectures is so large due to its excess flexibility. Then, the total area of configuration memory constitutes a large portion of reconfigurable logic in terms of area occupancy. Therefore, the reduction of the size of configuration data is indispensable for area-efficient reconfigurable logic.

In our reconfigurable architecture, the significant reduction of configuration data can be achieved, and enables to perform dynamic reconfiguration while the configuration memory is implemented as an external memory.

III. Reconfigurable Architecture

A. Overall Architecture

Overall architecture of our reconfigurable system is illustrated in Fig. 3, which consists mainly of a 32-bit RISC core as a host processor, a coarse-grained reconfigurable logic, a configuration memory, and a data buffer.

Configuration memory stores many of configuration data, and enables reconfigurable logic to change its context on runtime. Data buffer is a memory which can be accessed from both of processor and reconfigurable logic.

B. Reconfigurable Cell Architecture

As shown in Fig. 4, each of the cells consists of an interconnect part, which has the same structure for all kinds of cells, and a function part, having the different structure for each. The structure of interconnect part is made for suitable cooperation with adjacent cells.

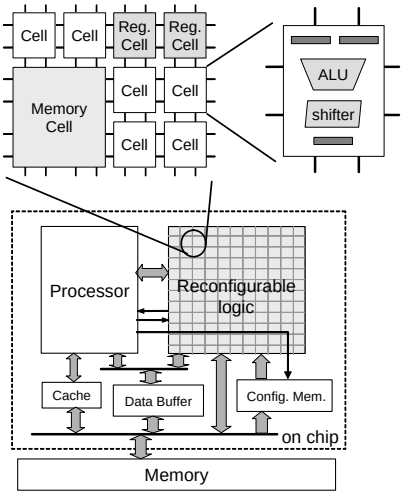

Fig. 3. Overall architecture.

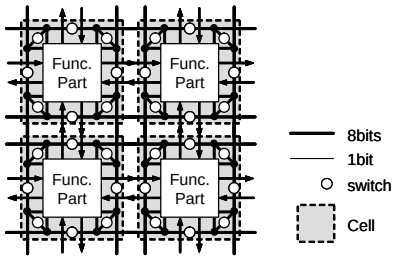

Fig. 4. Structure of reconfigurable array.

1) Interconnect: As illustrated in Fig. 5, the interconnect part is composed of eight 8-bit word lines "A0 $\sim$ A3, B0 $\sim$ B3" with eight switches, and eight 1-bit flag lines "fi0 $\sim$ fi3, fo0 $\sim$ fo3". Flag lines are used as carry-input, selector of multiplexer, write-enable of registers, and so on, where "fi0 $\sim$ fi3"are input from adjacent cells, and "fo0 $\sim$ fo3" are output to adjacent cells. Eight switches can change the connection of each two word lines, "A0 and B1", "A0 and B2", "A1 and B2", "A1 and B3", "A2 and B3", "A2 and B0", "A3 and B0", and "A3 and B1". Interconnection of word lines (i.e. status of switches) are defined by 8-bit configuration data.

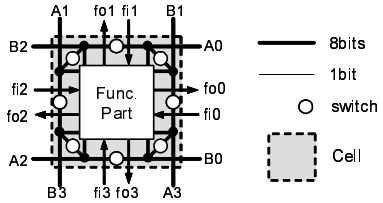

Fig. 5. Interconnect part.

2) Cell Variation: As illustrated in Fig. 6, reconfigurable logic adopts heterogeneous array architecture composed of four types of cells, i.e. basic cell, multiplication cell, register cell, and memory cell. Basic cell comprises 8-bit ALU and

basically supports ADD, SUB, AND, OR, and MUX operations. Multiplication cell executes 8-bit×8-bit multiplication. Register cell and memory cell provides 8-bit 16 words and 256 words storage, respectively. Memory cell occupies four times as large area as other types of cells.

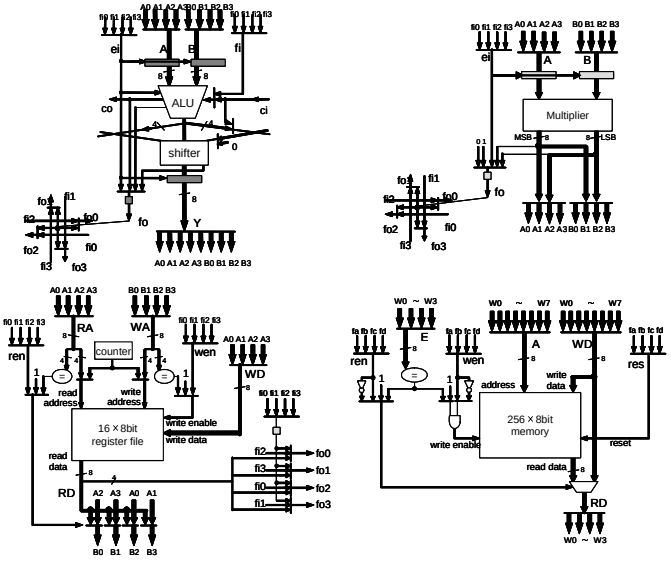

Fig. 6. Organization of function part of basic cell.

IV. Implementation Results

Evaluation of MPEG-2 decoder, H.263 decoder and MPEG-4 decoder implemented on the proposed reconfigurable system has been performed. In order to implement these decoding algorithms, as shown in Fig. 7, a heterogeneous yet based on basic pattern structure of four types of cells is proposed.

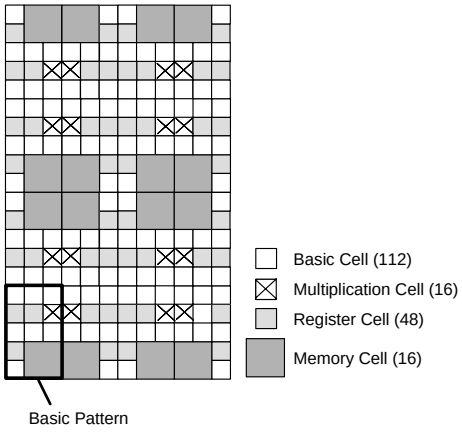

Fig. 7. Heterogeneous structure of 4 types of cells.

According to the software profiling results of MPEG-2 decoder, process partitioning between processor and reconfigurable logic is resolved as follows.

Processor: Header analysis, Calculation of moving vector, Control of reconfigurable logic.

Reconfigurable logic: VLD, IQ, IDCT, MC

The decode process is performed on macroblock basis. First, processor performs header analysis of a macroblock, then reconfigurable logic sequentially performs VLD, IQ, IDCT, and MC. Thus, the process, which is implemented on reconfigurable logic, is divided into some contexts, and performed with changing configuration of reconfigurable logic.

Particularly, MPEG-2 decoder and H.263 decoder are divided into three contexts of VLD/IQ, IDCT, and MC. On the other hand, MPEG-4 decoder is divided into four contexts of VLD, IQ, IDCT, and MC.

Since VLD operation does not fit to parallel processing, software implementation may achieve tolerable performance. However, the software implementation of VLD requires more high performance of host processor and lead to the increase of hardware cost. On the other hand, VLD, which is composed mainly of bit-level operations and look-up tables, can be implemented in hardware more efficiently than in software. Hence, in the proposed reconfigurable system, VLD operation is implemented in reconfigurable logic.

Table I shows the number of required cells for the context of each algorithms, and Table II shows the number of cycles for each context per one macroblock.

TABLE I
CELL UNILIZATION

		#cells			
		basic cell	mult. cell	reg. cell	mem. cell
	IDCT	52	12	9	8
MPEG-2	VLD/IQ	87	3	12	10
MPEG-2	MC	87	0	13	4
H.263	VLD/IQ	63	1	14	8
MPEG-4	VLD	83	0	13	9
MPEG-4	IQ	36	4	0	9
MPEG-4	MC	65	0	9	4

TABLE II
COMPUTATIONAL COST (1 MACROBLOCK)

		#cycles	
		Initialization	Operation
	IDCT	14	800
MPEG-2	VLD/IQ	32	140
MPEG-2	MC	57	515
H.263	VLD/IQ	32	25
MPEG-4	VLD	49	42
MPEG-4	IQ	29	394
MPEG-4	MC	44	496

Fig. 8 shows the process scheduling of typical macroblocks. In this performance estimation, processor and reconfigurable logic operate at the same clock frequency. The number of cycles for context switching of reconfigurable logic is 20 cycles, when the configuration data is transported over the configuration bus of 4×108-bit width. In our configuration mechanism, the configuration in each row of reconfigurable cell array can be performed in one cycle.

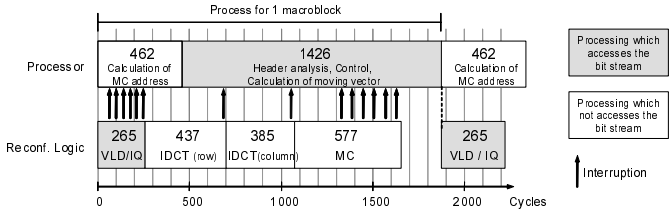

Fig. 8. Process scheduling on MPEG-2 decoder.

As shown in Fig. 8, while reconfigurable logic performs IDCT and MC for a macroblock, processor performes the header analysis for the next macroblock. Moreover, while reconfigurable logic performs VLD/IQ, processor operates the process, which does not need the bitstream.

As the results of process scheduling of MPEG-2 decoding, the numbers of cycles for operations of one macroblock are 1,888 and 1,664 on host processor and reconfigurable logic, respectively. On the other hand, for realtime processing of 720×480pixels 30fps MPEG-2 decoding, totally 40,500 macroblocks must be processed in one second, and thus a host processor must operate at the clock frequency of 77MHz or more. As for the reconfigurable logic, 68MHz of the clock frequency is requested. Critical path of the reconfigurable logic depends on the result of placement and routing. Implementation results by using Synopsys Design Compiler and HSPICE on a $0.18\mu m$ technology claim that the critical path of VLD/IQ, IDCT, and MC are 32.5ns, 8.8ns, and 11.0ns, respectively. When the reconfigurable logic operates at the maximum clock frequency, which are 30.8MHz, 114MHz, and 90.9MHz, realtime processing of MPEG-2 decoding can be attained. Considering the setting constraints of clock frequency on a real system, realtime processing of MPEG-2 decoding can be performed at the clock frequency of 30MHz for VLD/IQ and 90MHz for IDCT and MC.

However, these are almost the maximum clock frequency of VLD/IQ and MC. Thus, the proposed reocnfigurable architecture must preferably be implemented by more advanced technology.

In the same manner as MPEG-2 decoder, realtime processing of H.263 decoder and MPEG-4 decoder for 352×288pixels 30fps 384kbps bitstream can be implemented on the proposed reconfigurable system.

Table III summarizes implementation results, which demonstrate that multi-standard decoder can be implemented in the reconfigurable system with about 4 times as large hardware cost as a conventional MPEG-2 decoder.

TABLE III

IMPLEMENTATION RESULTS

Technology	$0.18\mu m$
Area of Reconfigurable logic	$4.94mm^2$
Delay on configurable cell	3.32μs
Size of configuration data	7,424bits/context
Configuration memory	8KB
Data buffer	6KB

V. CONCLUSIONS

The domain-specific area-efficient reconfigurable architecture, which has sufficient performance and flexibility for realtime processing of multi-standard decoder, has been proposed. In our reconfigurable architecture, the significant reduction of configuration data can be achieved, and enables to perform dynamic reconfiguration while the configuration memory is implemented as an external memory. Implementation results show that multi-standard decoder can be implemented in the reconfigurable system with about 4 times as large hardware cost as conventional MPEG-2 decoder.

***Abstract*- Vector Symbol Decoding (VSD) is a verification-based decoding technique for linear codes with large nonbinary symbols. The decoding steps for VSD for Convolutional codes or conv. VSD are somewhat different from the basic VSD for block codes. The detailed decoding steps for conv. VSD was shown in previous work, but they were for the performance investigations purpose and simulations only since the codewords were assumed to be all-zero codewords. In the implementation viewpoints, additional steps are needed to allow for any data sequence and codeword. This work explains these additional steps, which is mainly the step for updating the memory of the decoder.**

I. INTRODUCTION

Vector Symbol Decoding is a general decoding technique for large nonbinary symbols. It can be applied for both block and convolutional codes. VSD principle was first proposed by Metzner and Kapturowski [1] in 1990 and rediscovered by **C.** Haslach and A.J. Han Vinck [2] in 1999. Seo [3] presented the idea of VSD for convolutional code (conv. VSD) in 1991. The use of alternative choices for block code was shown by Metzner in 2003 [4]. Conv. VSD with alternative choices was first proposed by Tuntoolavest and Metzner [5] in 2002.

Previous works [6,7,8] on conv. VSD were mostly in theory. Its performance was done analytically or by simulations. More recent works by Tuntoolavest and Intharasakul [9,10] also focused on the implementation of Vector Symbol Decoder for convolutional codes. The detailed decoding steps of convolutional VSD were explained in [11]. The most recent application of VSD was for packet network [12], which showed the modified concept of VSD to handle errors, deletions and mis-ordering of packets. Although those steps in [11] were enough to simulate the performance, there are more necessary steps in the algorithm when the decoder is to be implemented. Especially, the performance investigation assumed all-zero code words without lost of generality. In the implementation, the data can be anything and the decoding algorithm must also provide for any data sequence other than all-zero sequence. The main concept is that the syndrome must be updated and the effect of decoded symbols needs to be cleared out.

II. BACKGROUND

Conv. VSD is a decoding technique for nonbinary convolutional code with a large symbol size. The typical size is 32-bit/symbols. It uses a verification-based technique that can confirm correct symbols quite easily. Conv. VSD is more attractive than Block VSD in that it can usually confirm correct symbols when it has received only a few symbols without having to wait for the whole received sequence. This reduces the complexity of the decoder and the delay time.

VSD usually assumes availability of two alternative received values for each symbol because the second choice can help improve the performance and simplify the decoding process. This paper will consider a conv VSD with two choices since the result from [8] suggested that the implementation should allow two choices. Example of received sequence with two choices is shown in Fig. 1.

To understand conv. VSD, a (3,2,2) convolutional code with

$$G(D)=\begin{bmatrix}1+D+D^2 & D^2 & 1\\ D & 1+D^2 & 1+D+D^2\end{bmatrix} \qquad (1)$$

is used as an example. Note that this is the code used in the implementation in [9,10].

The alternative choices may come from diversity such as space diversity with multiple received antennas. The first choice of each symbol may come from the antenna with highest SNR and the second choice of each symbol may come from the antenna with the next highest SNR that has different symbol value from the first choice. That is the first and second choices for each symbol are assumed to be different.

To check whether there is any error, the syndrome is computed. Since the symbols are nonbinary, each symbol is viewed as an r-bit vector. The syndrome computation is done by

$$\mathbf{S} = \mathbf{H}\cdot\mathbf{Y} = \mathbf{H}\cdot(\mathbf{V}+\mathbf{E}) = \mathbf{H}\cdot\mathbf{E} \qquad (2)$$

Where **S** is the syndrome matrix, **H** is the parity check matrix and **Y** is the received symbol matrix, **V** is the codeword matrix and **E** is the error matrix.

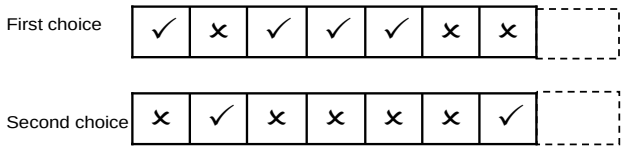

Figure 1. example of a received sequence with two alternative choices for each symbol where

✓ represents correct received symbol

✗ represents wrong received symbol

Supported by Kasetsart University Research and Development Institute

If the syndrome matrix **S** is a zero matrix, the decoder decides that no error occurs and it can transmitted the corresponding symbols out immediately. If **S** is not a zero matrix, the decoder will first try to correct the error using one syndrome vector from the first row of the syndrome matrix. For the (3,2,2) code, a syndrome vector involves 3 received symbols. If it can not correct, then it will increase the number of syndrome vector one by one.

Each additional syndrome vector involves three more received symbols. The decoder will also try to use second choice to correct the error symbol because when the second choice is correct, VSD can often substitute the wrong first choice with the correct second choice. If there are still some errors left, the decoder will then decode by using the concept called "null combinations" explained in [11]. Basically, null combination is a verification method that helps the decoder confirms all the correct codewords and discovers an error-locating vector, which reveals the positions of error symbols. Then the value of error symbols can be computed by matrix conversion.

The parity check matrix H for this (3,2,2) code was given in [5] as

$$H = \begin{bmatrix} 1&1&1&0&0&0&0&0&0&0&0&0&0&0&0 \\ 0&1&1&1&1&1&0&0&0&0&0&0&0&0&0 \\ 0&1&0&0&1&1&1&1&1&0&0&0&0&0&0 \\ 1&0&0&0&1&0&0&1&1&\cdots&\cdots&\cdots&\cdots&\cdots&\cdots \\ 1&1&1&1&0&0&0&1&0&\cdots&\cdots&\cdots&1&1&1 \\ 0&0&0&1&1&1&1&0&0&\cdots&\cdots&\cdots&0&1&1 \\ 0&0&0&0&0&0&1&1&1&\cdots&\cdots&\cdots&0&1&0 \\ \vdots&\vdots&\vdots&\vdots&\vdots&\vdots&\vdots&\vdots&\vdots&\cdots&\cdots&\cdots&1&0&0 \\ 0&0&0&0&0&0&0&0&0&0&0&0&1&1&1 \end{bmatrix} \quad (3)$$

Example: Suppose the transmitted symbols are ***A, B, C, D, E, F,…,Z*** where each alphabet represents an r-bit vector. Let the received sequence be as shown in fig. 2 where there is an error called $\mathbf{e_3}$ in the third symbol of the first choice and no error anywhere else. There is also a correct second choice for the third symbol.

Example of decoding steps:

1. The decoder begins by computing the first syndrome vector $\mathbf{s_1}$ according to (2) where the parity matrix for one syndrome comes from the first row and the first three columns of (3).

$$\mathbf{s_1} = \mathbf{H\,Y} = \mathbf{h_1\,Y} = [\,1\,1\,1\,]\,[\,\boldsymbol{A}\ \boldsymbol{B}\ (\boldsymbol{C} \oplus \boldsymbol{e_3})\,]^T$$
$$= \boldsymbol{A} \oplus \boldsymbol{B} \oplus \boldsymbol{C} \oplus \boldsymbol{e_3} \quad (4)$$

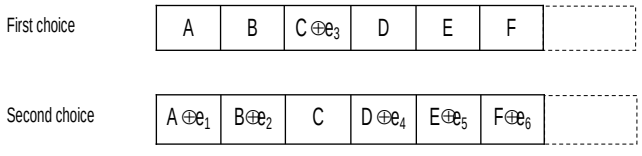

Figure 2 The first and second choice of the received sequence where e_i represent the error for the i^{th} received symbol and ⊕ represents r-bit exclusive-OR operation.

Where ⊕ is an r-bit XOR operation.

The basic decoding concepts indicate that the syndrome value must be zero if the received sequence is a codeword. Therefore,

$$\mathbf{H{\cdot}V} = \mathbf{h_1\,V} = [\,1\,1\,1\,]\,[\,\boldsymbol{A}\ \boldsymbol{B}\ \boldsymbol{C}]^T$$
$$= \boldsymbol{A} \oplus \boldsymbol{B} \oplus \boldsymbol{C} = \mathbf{0} \quad (5)$$

From (4) and (5),

$$\mathbf{s_1} = \mathbf{e_3} \quad (6)$$

Equation (6) shows that the first syndrome vector has the same value as the error. The decoder knows that error occurs since the syndrome is nonzero.

2. Then the decoder computes the differences for each symbol between its first and second choice as indicated in [11]. The differences are shown in fig. 3.

3. Next, the decoder compares the syndrome value to the differences shown in Fig. 3 and finds that the syndrome value is the same as the difference of the third symbol. This means that the third symbol is wrong and the error value has been revealed as the syndrome value. Knowing both the position of the error symbol and the error value, the decoder can easily correct this. It can be seen that the correction with one syndrome succeeds for the case of no more than one error symbol with a correct second choice.

The first three steps follow the steps explained in [11].

4. In the original decoding steps for the performance analysis, the decoder will then transmit the three correct symbols out as the start of the codeword. Then, the decoder will start again at the fourth received symbol and treat the fourth symbol (D) as the first received symbol and repeat step 1-3. If there is no error, the new first syndrome $\mathbf{s_1'}$ will be

$$\mathbf{s_1'} = [\,1\,1\,1\,]\,[\,\boldsymbol{D}\ \boldsymbol{E}\ \boldsymbol{F}]^T$$
$$= \boldsymbol{D} \oplus \boldsymbol{E} \oplus \boldsymbol{F} = \mathbf{0} \quad (7)$$

If the syndrome is zero as shown in (7), the decoder can transmit these three symbols out and start treating the seventh symbol as the first received symbol again.

If there are errors that can not be corrected with one syndrome, the decoder will increase the number of syndrome one by one. Each time, the decoder increase one syndrome, it has to take three more received symbols into the calculation for the case of (3,2,2) code. Note that for a (n,k,m) code, each syndrome involves n received symbols. If the decoder can correct with two syndromes, it will transmit six symbols out and restart and so on.

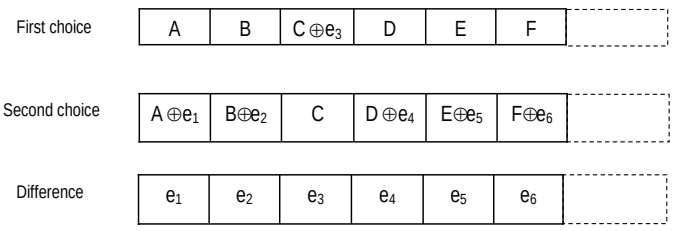

Figure 3 The differences between the first and the second choice for this example

It is important to emphasize that VSD has two main decoding parts. The first is called "correct with second choice" , which can be viewed as a screening part that helps reduce the number of error symbols. In this first part, the decoder can pick some correct second choices to replace the wrong first choices. The "correct with second choice" that uses one syndrome was explained in Step 1 to 3. The "correct with second choice" can also use many syndromes, where the error value and the error symbol index are found when the difference between the first and the second choice for that symbol is in the row space of the syndrome matrix.

The second part is called "correct with null combination" is the main part and more complicated. Briefly, this part can correct errors by using verification method to confirm the correct symbols and to find error locating vector that can locate the positions of the error symbols. The error values can then be discovered from the concept of

$$\mathbf{E} = \mathbf{H}^{-1} \cdot \mathbf{S} \qquad (8)$$

The details of "correct with second choice" and "decode with null combination" was explained in [4,11].

III. The Proposed Additional Decoding Step

A. Concept

This paper will focus on the Step 4 of section II. For the all-zero codeword (all transmitted symbols are zero-value), this original step worked. Since all-zero codeword can be assumed without lost of generality in the performance analysis, this was done for simplicity in previous works. However, for other applications, the data sequence can be anything and the codewords may not be all-zero codewords. In this more general case, additional step is needed to clear the memory out of the decoder because convolutional code is a code with memory. For step 4, when the decoder has output the first three symbols out, the decoder can not immediately treat the fourth symbol (***D*** in this example) as the first received symbol. To understand how to clear the memory, consider the following example.

Suppose again that the transmitted symbols are ***A, B, C, D, E, F,…,Z***. Computation of the second syndrome involves the symbols ***D***, ***E*** and ***F*** and the vector $\mathbf{h}_2$, which is the vector from the second row and the first six columns of the parity check matrix **H**.

$$\mathbf{h}_2 = [0\ 1\ 1 \quad 1\ 1\ 1] \qquad (9)$$

Therefore, the syndrome value will be

$$\mathbf{s}_2 = \mathbf{H}\,\mathbf{Y} = \mathbf{h}_2\,\mathbf{Y} = [0\ 1\ 1\ 1\ 1\ 1]\,[\boldsymbol{A\ B\ C\ D\ E\ F}]^{\mathrm{T}}$$
$$= \boldsymbol{B \oplus C \oplus D \oplus E \oplus F} = \mathbf{0} \qquad (10)$$

Comparing (7) and (10), it is obvious that the difference between the original step 4 and the new proposed step 4 is that for general date sequence where symbols ***B*** and ***C*** may be nonzero, they cannot be omitted.

When the calculation in (10) is performed by the decoder, the decoder has already known the values of symbols ***B*** and ***C*** since it has transmitted the first three symbols ***A***, ***B*** and ***C*** out. Therefore, (10) can be computed with no problem. Suppose there is no error in ***D***, ***E***, ***F*** or there is a wrong first choice with correct second choice, which can be corrected by one syndrome. The decoder can then transmit these three additional symbols out and go on to the next three received symbols. The vector $\mathbf{h}_3$ from the parity check matrix will then be

$$\mathbf{h}_3 = [0\ 1\ 0 \quad 0\ 1\ 1 \quad 1\ 1\ 1] \qquad (11)$$

Suppose there is an error in symbol ***G*** and symbol ***H***, the syndrome value will be

$$\mathbf{S}_3 = \mathbf{H}\,\mathbf{Y} = \mathbf{h}_3\,\mathbf{Y}$$
$$= [0\ 1\ 0\ 0\ 1\ 1\ 1\ 1\ 1]\,[\boldsymbol{A\ B\ C\ D\ E\ F\ (G \oplus e_7)\ (H \oplus e_8)\ I}]^{\mathrm{T}}$$
$$= \boldsymbol{B \oplus E \oplus F \oplus (G \oplus e_7) \oplus (H \oplus e_8) \oplus I}$$
$$= \boldsymbol{e_7 \oplus e_8} \qquad (12)$$

In this case, the decoder can not correct with one syndrome because the syndrome will not be a match for any difference. The decoder will then need to increase the number of syndrome to two.

$$\mathbf{S}_4 = \mathbf{H}\,\mathbf{Y} = \mathbf{h}_4\,\mathbf{Y}$$
$$= [1\ 0\ 0\ 0\ 1\ 0\ 0\ 1\ 1\ 1\ 1\ 1] \cdot [\boldsymbol{A\ B\ C\ D\ E\ F\ (G \oplus e_7)\ (H \oplus e_8)\ I\ J\ K\ L}]^{\mathrm{T}}$$
$$= \boldsymbol{A \oplus E \oplus (H \oplus e_8) \oplus I \oplus J \oplus K \oplus L}$$
$$= \boldsymbol{e_8} \qquad (13)$$

With two syndromes, the decoder finds that symbol ***H*** is wrong since the difference between the first and the second choice of symbol ***H*** has the same value as $\mathbf{s}_4$. Obviously, after the decoder corrects symbol ***H***, it can then correct symbol ***G***.

The main point is still that the decoder must update the memory with symbols ***A, B***, ***E*** and ***F***, which are known to the decoder, otherwise the results will be wrong. For more syndromes, the results are summarized in section IV.

B. Memory size

The memory size that the decoder has to keep for the updating purpose can be seen from the parity check matrix of the code. For this (3,2,2) code with the parity check matrix **H** in (3), the syndrome computations always involve no further than 12 previous symbols as seen by the fifth row of **H**. In other words,

$$\mathbf{h}_5 = [1\ 1\ 1 \quad 1\ 0\ 0 \quad 0\ 1\ 0 \quad 0\ 1\ 1 \quad 1\ 1\ 1] \qquad (14)$$

All following $\mathbf{h}_i$, i = 6,7,... are exactly the same as $\mathbf{h}_5$ and these $\mathbf{h}_i$, i = 5,6,7,...can be considered as being in the steady state, where $\mathbf{h}_i$, i = 1,2,3,4 may be considered as being in the transient state.

For a general (*n*,*k*,*m*) code, the syndrome computations will involve no more than $n \cdot k \cdot m$ previous symbols.

IV. Results

The updated memory can be summarized as shown in table 1 for the (3,2,2) code in consideration. It can be seen form table 1 that the syndrome calculation is in the steady state from $\mathbf{s}_5$ and the decoder will need no further than 12 previous symbols. Therefore, the memory of more than 12 decoded symbols can be cleared and the decoder can treat the 12th previous symbol as the start of the new received sequence. For example, computation of $\mathbf{s}_6$ can treat the 4th symbol as the new 1st symbol. With this clearing of memory, the decoder can

Table 1 Proposed syndrome calculation for the selected (3,2,2) code

parity vector	Proposed Syndrome Computation
$\mathbf{h}_1$ = [111]	$\mathbf{s}_1$ = XOR of received symbol 1,2,3
$\mathbf{h}_2$ = [011 111]	$\mathbf{s}_2$ = XOR of received symbol 2,3,4,5,6
$\mathbf{h}_3$ = [010 011 111]	$\mathbf{s}_3$ = XOR of received symbol 2,5,6,7,8,9
$\mathbf{h}_4$ = [100 010 011 111]	$\mathbf{s}_4$ = XOR of received symbol 1,5,8,9,10,11,12
$\mathbf{h}_5$ = [111 100 010 011 111]	$\mathbf{s}_5$ = XOR of received symbol 1,2,3,4,8,11,12,13,14,15
$\mathbf{h}_6$ = [000 111 100 010 011 111]	$\mathbf{s}_6$ = XOR of received symbol 4,5,6,7,11,14,15,16,17,18
$\mathbf{h}_7$ = [000 000 111 100 010 011 111]	$\mathbf{s}_7$ = XOR of received symbol 7,8,9,10,14,17,18,19,20,21

always use the calculation of $\mathbf{s}_5$ in the steady state without the need of $\mathbf{s}_6$, $\mathbf{s}_7$ and so on.

V. DISCUSSIONS

This paper shows that for general data sequence, it is necessary to clear the memory of the convolutional vector symbol decoder to obtain the correct results. This is because convolutional code has memory. The updating of memory was explained in concepts with some examples. The results showed the proposed syndrome calculation. This is more complicated than the original syndrome calculations used in the performance evaluation in previous work, which was explained in section II.

It should be emphasized that although the decoder must keep previous decoded symbol values for the calculation of later syndromes, those decoded symbols can still be transmitted out immediately after they are decoded. This means that the attractive feature of conv. VSD over block VSD still exits. This attractive feature is the fact that block VSD can decode the received sequence only when the whole block has been received as is the nature of block codes, while conv. VSD can decode and transmit out when only a few symbols have been received.

VI. CONCLUSIONS

The result is important and will be used for the implementation of conv. VSD decoder, which is under development on Field Programmable Gate Array (FPGA) board at this time. This works strengthen the point that it is a very big step to go from simulations to implementation as even algorithm may need to be modified and all assumptions must be reconsidered.

ACKNOWLEDMENT

The author would like to thank Mr. Auttaphud Seubnaung, a graduate student for alerting the author of the problem.

MAP Decoding for Polynomial Ring Convolutional Trellis Codes for MPEG-4 Image Transmission System over Rician Fading Channels

Srijidtra Mahapakulchai
Department of Electrical Engineering, Kasetsart University, Thailand, E-mail:fengsjm@ku.ac.th

Abstract— **The crucial part of MAP decoding process is the computation of branch metrics. We derive the computation of new branch metrics, customized for Rician fading channels. These metrics are assigned in Viterbi decoder to perform MAP sequence detection. We also analyze the performance of our proposed MAP decoding with polynomial (non-systematic) ring trellis codes. These codes are based on the combination of polynomial ring convolutional codes and CPFSK modulation. The simulation results show the improvement in PSNR about $0.2 - 0.25$ dB on average.**

Keywords— **MAP decoding, Ring convolutional codes, Trellis-coded modulation, Joint source-channel coding, Rician fading channels.**

I. System Overview

The overall system block diagram is illustrated in Fig. 1.The MPEG-4 [1] source encoder produces the 4-ary symbol stream of the lowest frequency subband (LFS) and higher frequency subband (HFS) packet. Detail about the MPEG-4 EZW algorithm and the HFS packet structure can be found in [2]. This stream is passed though the

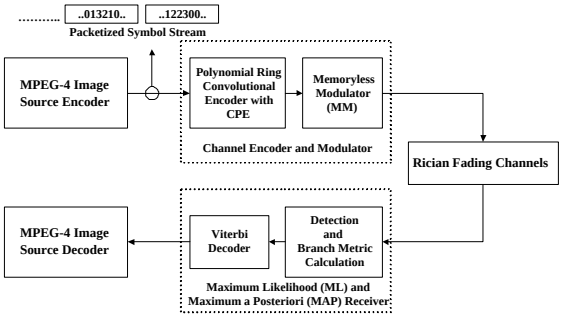

Fig. 1. System block diagram of the MPEG-4 still image transmission system using CPFSK and ring convolutional codes.

channel encoder and modulator system, which are a rate $\frac{1}{2}$ polynomial convolutional encoder (CE) over ring Z_4 and CPFSK with $h = \frac{1}{4}$, respectively. The CPFSK system is decomposed into a continuous phase encoder (CPE) and a memoryless modulator (MM)[3]. The overall encoder is the combination of the CE and the CPE. The MM maps a code symbol into the in-phase and quadrature phase components of a baseband CPFSK signal. These two components of a signal are then corrupted by noise and distortion from Rician fading channel [4]. At the receiver, we employ both the maximum likelihood (ML) and the maximum *a posteriori* (MAP) receiver consisting of a demodulation process, a branch metric calculator, and a Viterbi decoder[5]. The MAP receiver is applied only when a 4-ary zerotree symbol sequence in each HFS packet is transmitted. The decoded 4-ary stream is fed into MPEG-4 source decoder resulting in a reconstructed image.

II. Ring Convolutional Trellis-coded CPFSK and MAP Decoding Derivation

When an external convolutional encoder (CE) is used in conjunction with the CPFSK system (CPE+MM), the state of the overall encoder (CE+CPE) is of concern. Furthermore, a rate 1/2 CE is used in conjunction with a rate 1/2 CPE, and to be able to algebraically combine them into a single encoder, we need to first convert the CPE into an equivalent encoder of rate 2/4 [7]. To illustrate this, we first discuss the conversion in detail, and then we show how to combine the rate 1/2 CE with an equivalent encoder 2/4, resulting in the overall encoder of rate 1/4. From the block diagram shown in Fig. 2, we obtain four

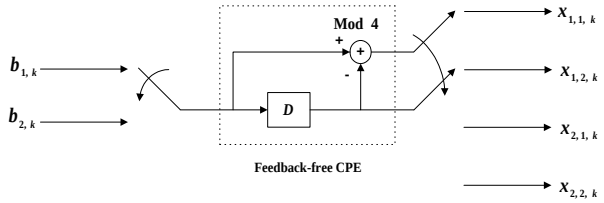

Fig. 2. The block diagram of an equivalent encoder of rate 2/4

equations corresponding to the four outputs $x_{1,1,k}$, $x_{1,2,k}$, $x_{2,1,k}$ and $x_{2,2,k}$ as: $x_{1,1,k} = b_{1,k} - b_{2,k-1}$, $x_{1,2,k} = b_{2,k-1}$, $x_{2,1,k} = b_{2,k} - b_{1,k}$, $x_{2,2,k} = b_{1,k}$. Note that the input $b_{2,k-1}$ is the initial value of the state which is stored in the delay D. That is why we have the first two equations. Moreover, the modulo sum of the first two equations results in the value of $b_{1,k}$ ($b_{1,k} = x_{1,1,k} + x_{1,2,k}$ *mod* 4) and for the modulo sum of the last two equations, we obtain the value of $b_{2,k} = x_{2,1,k} + x_{2,2,k}$ *mod* 4. Fig. 3 shows all possible phase transitions produced from the two input symbols $b_{1,k}$ and $b_{2,k}$. We observe that the value of $b_{2,k}$ is associated with the value of the phase state at time kT. In this section, the notation of the phase state $b_{2,k}$ is used in the same manner as that of the phase state $x_{2,k}$ explained [6]. The difference here is that $b_{2,k}$ is updated every two signal intervals, while $x_{2,k}$ is updated every signal interval. Therefore, we are now interested in finding $b_{2,k}$ for which the conditional probability $P(z_k|b_{2,k+1}, b_{2,k})$ is maximum. Note that z_k is the observed signal within two signal intervals. By assuming AWGN channel, the branch metric computation for MAP decoding within two signal intervals becomes

$$\lambda(s_{m,k}) = -\sum_{i=1}^{2N} z_{k,i} s_{m,k,i} - \frac{N_0}{2} \ln P(b_{2,k+1}|b_{2,k}). \quad (1)$$

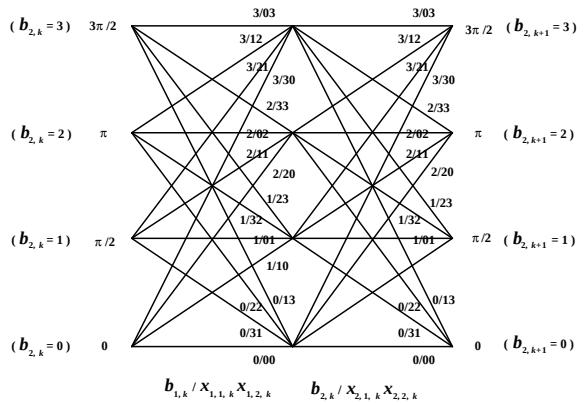

Fig. 3. The phase trellis diagram of the block diagram shown in Fig. 2.

In this case, the maximum number of possible path in the trellis that are required to compute the branch metric is 64. Moreover, the $s_{m,k}$ is the transmitted signal over two signal intervals. From the block diagram of CPE in Fig. 2, the four input-output relationships can be rewritten in another form as $X_{1,1}(D) = b_1(D) - Db_2(D)$, $X_{1,2}(D) = Db_2(D)$, $X_{2,1}(D) = b_2(D) - b_1(D)$, $X_{2,2}(D) = b_1(D)$. This is similar to taking the z-transform of the previous four equations, but we use the parameter D instead of z ; also, D is not a complex variable but a delay variable. Thus, we obtain the transfer function [7] as follows.

$$X = B \begin{bmatrix} 1 & 0 & 3 & 1 \\ 3D & D & 1 & 0 \end{bmatrix}, \qquad (2)$$

where X and B are row vectors corresponding to outputs $[X_{1,1}(D)\ X_{1,2}(D)\ X_{2,1}(D)\ X_{2,2}(D)]$ and inputs $[B_1(D)\ B_2(D)]$, respectively. Observe that the number 3 comes from -1 modulo 4.

For example, if the input row vector $B = [2D+1\ \ 1]$, we obtain the output row vectors $X = [D+1\ \ D\ \ 2D\ \ 2D+1]$. The block diagram of the overall encoder X is shown in Fig. 4. Notice that the realization of the overall encoder shows the relationship between input symbol u_k and four output symbols $x_{1,1,k}$, $x_{1,2,k}$, $x_{2,1,k}$ and $x_{2,2,k}$ without explicitly showing the value of the parameters $b_{1,k}$ and $b_{2,k}$. However, we can compute these parameters from the relationship from the block diagram shown in Fig. 2 described earlier. It is worth mentioning that the parameters $b_{1,k}$ and $b_{2,k}$ enable us to determine the transition of the phase state shown in Fig. 3. Fig. 5 shows the trellis diagram of the

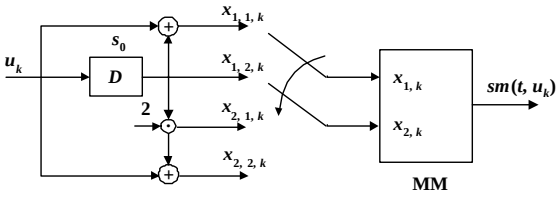

Fig. 4. The block diagram of overall encoder

block diagram in Fig. 4 as well as its corresponding phase trellis diagram. In this example, the total state numbers is

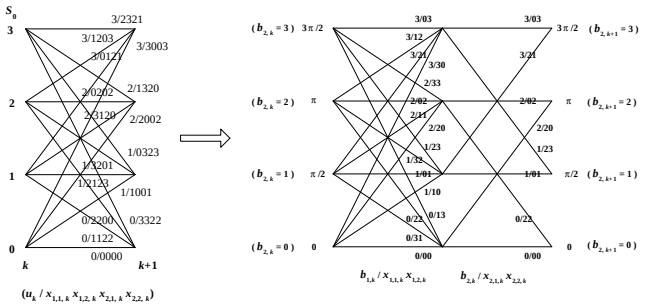

Fig. 5. The trellis diagram and the phase trellis diagram of the block diagram shown in Fig. 4.

four and the total path numbers in the trellis are 16. Emphasize that each path in the trellis diagram corresponds to the phase transition of two signal intervals and the value of S_0 is identical to the value of b_2. Therefore, the branch metric in Eq. (1) can be rewritten as

$$\lambda(s_{m,k}) = -\sum_{i=1}^{2N} z_{k,i} s_{m,k,i} - \frac{N_0}{2} \ln P(S_{0,k+1}|S_{0,k}). \qquad (3)$$

Next we would like to find the relationship between the state variable S_0 and input symbol u. By observing the structure of the overall encoder shown in Fig. 4, we found out that $S_{0,k+1} = u_k$. This fact is also evident by observing (in Fig. 5) that all branches entering the state $S_{0,k+1}$ corresponds to the input $u_k = S_{0,k+1}$. Thus, the branch metric in Eq. (3) now becomes $\lambda(s_{m,k}) = -\sum_{i=1}^{2N} z_{k,i} s_{m,k,i} - \frac{N_0}{2} \ln P(u_k|u_{k-1})$.

When the total state number of the overall encoder is greater than four, we may use $P(u_k|u_{k-1})$ more than one time. To see how one can combine $P(u_k|u_{k-1})$ into the branch metrics, let us first observe the structure of the overall encoder $G_{all}(D)$, whose block diagram is shown in Fig. 6. The block G'' contains only adders and multipliers connected according to the transfer function of $G_{all}(D)$; G'' does not contain any delay elements. The external multipliers, $a_1, \cdots, a_{m-1}$, are necessary whenever a reduction of the total number of states is possible. From Fig. 6, one sees

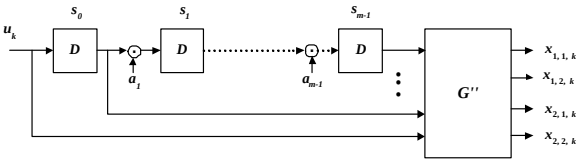

Fig. 6. The block diagram of the overall encoder, G_{all}.

that the first delay S_0 always contains the value of the previous input u_{k-1}. It implies that when we know the value of S_0, we then know what the previous input is. It also implies that at each state, all incoming branches are associated with the same input. This knowledge allows us to incorporate the source transition probabilities $P(u_k|u_{k-1})$ into each branch metric. Moreover, for a trellis having a total number of states more than four, one will have to use $P(u_k|u_{k-1})$ more than once. The method for automatically incorporating $P(u_k|u_{k-1})$ into all branch metrics must be

implemented. Note that the method is also necessary for performing a code search [10].

The technique used here is that for a given state number SN, the value of S_0 is automatically computed as follows

$$S_0 = SN \ mod \ 4, \tag{4}$$

where *mod* indicates a modulo operation. For instance, when the state number is five, the value of S_0 becomes 5 $mod\ 4 = 1$. It is worth mentioning that from the realization of the overall encoder shown in Fig. 6, the state number SN can be computed by

$$SN = S_0 + S_1 D_1 + S_2 D_2^2 + \cdots + S_{m-1} D_{m-1}^{m-1}, \tag{5}$$

where

$$D_i = \begin{cases} 2, & i = k, k+1, \ldots, m-1, \\ 4, & i < k, \end{cases}$$

and k = the minimum index i such that $a_i = 2$. Note that in the case when none of the external multipliers a_i is equal to two, $D_i = 4$, for all i. To verify the validity of Eq. 4, we simply substitute Eq. 5 into Eq. 4 and then show that it can be reduced to S_0. Observe that the terms $S_2 D_2^2, S_3 D_3^3, \ldots, S_{m-1} D_{m-1}^{m-1}$ contain a factor of 4 since D_i is either 2 or 4. As a result, the modulo 4 of these terms are identically zero. For the term $S_1 D_1$, we separate into two cases:

- *Case I when* $D_1 = 4$*:* the term $S_1 D_1$ contains a factor of 4 and so it is reduced to zero after a modulo 4 operation;
- *Case II when* $D_1 = 2$*:* the definition of D_i implies that $a_1 = 2$. In this case, S_1 can only be either 0 or 2 since from the realization of the overall encoder S_1 must contains a factor of a_1. Thus, the term $S_1 D_1$ also contains a factor of 4 and it is reduced to zero after a modulo 4 operation.

After knowing the value of $S_{0,k}$, we then use it as the value of u_{k-1}. Thus, at state number SN, the branch metric that corresponds to the current input u_k is incorporated with the source transition probability $P(u_k|u_{k-1}) = P(S_{0,k+1}|S_{0,k})$.

III. Rician Fading Channel Modelling

Let the transmitted baseband signal is $s_l(t)$. The received equivalent lowpass signal can be written as

$$r_l(t) = (1 + \beta e^{-j\phi}) s_l(t) + n_{wl}(t), 0 \le t \le T, \tag{6}$$

where n_{wl} is the complex-valued white Gaussian noise random process with two-sided spectral density $N_0/2$. Since the channel is sufficiently slow, the phase shift ϕ can be estimated from the received signal. Without loss of generality, we assume ϕ to be zero. The parameter β is defined as

$$\beta = \sqrt{(f_i(t)/\sqrt{2S})^2 + (f_q(t)/\sqrt{2S})^2}, \tag{7}$$

where $f_i(t)$ and $f_q(t)$ are the in-phase and quadrature phase components of the scattered multipath signal, which are Gaussian random variables with zero mean and variance equal to σ^2. S is the signal power, $S = Es/T$, where T is a symbol interval. Let γ_b be $(1+\beta)^2 E_s/N_0$. The probability density function of γ_b can be found in [4] as

$$p(\gamma_b) = \frac{1+\gamma}{\bar{\gamma_b}} e^{-\gamma-(1+\gamma)\gamma_b/\bar{\gamma_b}} I_0\left(2\sqrt{\frac{\gamma(1+\gamma)\gamma_b}{\bar{\gamma_b}}}\right), \tag{8}$$

where

$$\bar{\gamma_b} = \frac{1+\gamma}{\gamma} E_s/N_0, \tag{9}$$

and $\gamma = S/\sigma^2$ is the ratio of the direct path power to the scattered path power. If the direct path is blocked by any structures, the fading channel is called a Rayleigh channel. The channel can be simulated by letting the signal power S be small compared to the scattered path power σ^2.

IV. MAP Decoding Derivation for Rician Fading Channels

To construct the MAP decoder for the CPFSK system, we observe the data samples $z_{k,i}$. During time interval $kT \le t \le (k+1)T$, the observed samples can be written as $z_{k,i} = (1+\beta)s_{m,k,i} + n_{k,i}$ where $i = 1, 2, \cdot, N$. For a slowly fading channel, β is a constant during each signal interval. Al Semari *et al.* [8] assume that the fading values can de determined, *i.e.* they estimate channel state information (CSI). Therefore, this information can be incorporated into the decoding metric. We first follow this assumption. However, we shall show later that by using only the mean value of β, no estimation is necessary, and some improvement is still obtained. Assuming CSI, the conditional probability becomes

$$P(z_k|s_{m,k}) = \frac{1}{(\sqrt{\pi N_0})^N} e^{-\left[\sum_{i=1}^{N} \frac{(z_{k,i} - \alpha s_{m,k,i})^2}{N_0}\right]}, \tag{10}$$

where $\alpha = (1+\beta)$. The designed MAP decoding is based on a kind of probabilistic decoder known as Viterbi decoder [5]. This decoder is said to be "optimal" because it is the solution to the problem of maximum *a posteriori* probability (MAP) estimation of the state sequence of a finite-state discrete-time Markov process. This estimation problem is equivalent to finding the state sequence for $P(\mathbf{z}|\mathbf{x})P(\mathbf{x})$ is maximum, where $\mathbf{z}$ and $\mathbf{x}$ are the observed and state sequences respectively. By considering the first order Markov process and memoryless noise properties, we aim to search for the state sequence $\mathbf{x}$ which satisfies arg $\max_{\mathbf{x}} P(\mathbf{z}|\mathbf{x})P(\mathbf{x})$. And it is equal to

$$\arg \max_{\mathbf{x}} \prod_{k=0}^{K-1} P(z_k|x_k, x_{k-1}) P(x_k|x_{k-1}). \tag{11}$$

Since the natural log function, ln(.) is a monotonic function, we can apply this function to Eq.(11) without changing its solution. Also, we define the negative value of the component inside the summation as the branch metric, $\lambda(x_k, x_{k-1}) = -\ln P(z_k|x_k, x_{k-1}) - \ln P(x_k|x_{k-1})$. we obtain the branch metric $\lambda(s_{m,k})$ as $\lambda(s_{m,k}) = -\sum_{i=1}^{N} z_{k,i} s_{m,k,i} - \frac{N_0}{2\alpha} \ln P(x_{2,k+1}|x_{2,k})$. Since $P(x_{2,k+1}|x_{2,k}) = P(u_k|u_{k-1}) = P(u_{k+1}|u_k)$, where $\mathbf{u}$ is the input sequence. The new branch metric becomes $-\sum_{i=1}^{N} z_{k,i} s_{m,k,i} - \frac{N_0}{2\alpha} \ln P(u_k|u_{k-1})$. When an external encoder (CE) is included in the system, we have to consider the conditional probability $P(z_k|S_{0,k+1}, S_{0,k})$ instead of $P(z_k|x_{2,k+1}, x_{2,k})$ as explained in Section . The difference here is that the effect of the fading amplitude is included in the computation of the conditional probability

$P(z_k|S_{0,k+1}, S_{0,k})$ via the relationship in Eq. (10). Therefore the branch metric becomes

$$\lambda(s_{m,k}) = -\alpha_1 \sum_{i=1}^{N} z_{k,i} s_{m,k,i} - \alpha_2 \sum_{i=N+1}^{2N} z_{k,i} s_{m,k,i} - \frac{N_0}{2} \ln P(S_{0,k+1}|S_{0,k}), \quad (12)$$

where α_1 and α_2 are the constant fading amplitude during the first and second signal interval, respectively.

V. Simulation Results

The "Lena" image is used as our information source. This grayscale image has a size of 512×512 pixels. This image is compressed by using the subband coding technique and then the higher frequency subband (HFS)is packetized. For a noiseless channel, the peak signal to noise ratio (PSNR) of the reconstructed image and its compression ratio is 31.83 dB and 31:1, respectively.

TABLE I
The average PSNR of the reconstructed "Lena" image using ML and MAP decoding for Rician channel with $\gamma = -43$ dB

$\overline{\gamma_b}$ with $\gamma = -43$ dB	PSNR(dB) with ML decoding	PSNR(dB) with MAP decoding (Improvement in dB)
1.25	10.478	10.509 (0.031)
2.50	14.921	15.049 (0.128)
3.75	20.788	21.006 (0.218)
5.00	25.720	25.890 (0.170)
6.25	28.880	28.926 (0.046)
7.50	30.373	30.408 (0.035)

Table I, II and III summarize the average PSNRs for three Rician fading channels with $\gamma = -43, -33$ and -23 dB, respectively. Since γ is the ratio of the direct path power to the scattered path power, therefore $\gamma = -\infty$ dB is used for Rayleigh fading channel. For Table I, the maximum improvement is about 0.22 dB and it occurs at the average PSNR about 21 dB with $\overline{\gamma_b} = 3.75$ dB. The corresponding average symbol error rate (SER) is about 0.002. As γ increases, Table II shows the maximum improvement of about 0.26 dB at $\overline{\gamma_b} = 3.75$ dB. As expected, we also have slight improvement of the average PSNR about 22 dB.

Finally, from Table III, the maximum improvement is about 0.2 dB and it is located again at $\overline{\gamma_b} = 3.75$ dB. At this point, we have the average PSNR of about 25 dB which is higher than the results in the previous cases. The SER is of 0.00075.

VI. Conclusion and Future Work

In this work, we derive the branch metric for MAP decoding. This derivation is based on the use over Rician fading channel. The performances comparison of our proposed MAP and ML decoding are summarized. The improvement on average PSNRs is approximately 0.2-0.26 dB at SER of about 0.001.

TABLE II
The average PSNR of the reconstructed "Lena" image using ML and MAP decoding for Rician channel with $\gamma = -33$ dB

$\overline{\gamma_b}$ with $\gamma = -33$ dB	PSNR(dB) with ML decoding	PSNR(dB) with MAP decoding (Improvement in dB)
1.25	11.137	11.172 (0.035)
2.50	15.719	15.852 (0.133)
3.75	21.953	22.217 (0.264)
5.00	26.647	26.775 (0.128)
6.25	29.331	29.409 (0.078)
7.50	30.627	30.645 (0.018)

TABLE III
The average PSNR of the reconstructed "Lena" image using ML and MAP decoding for Rician channel with $\gamma = -23$ dB

$\overline{\gamma_b}$ with $\gamma = -23$ dB	PSNR(dB) with ML decoding	PSNR(dB) with MAP decoding (Improvement in dB)
1.25	13.613	13.690 (0.077)
2.50	19.469	19.676 (0.207)
3.75	25.129	25.333 (0.204)
5.00	28.783	28.816 (0.033)
6.25	30.474	30.475 (0.001)
7.50	31.138	31.138 (0.000)

VII. Acknowledgment

The author thanks Mr. Pakin Thanakulporn and Ms. Wanpen Janpanichsub for patiently running the simulation program. Moreover, the author appreciates all the comments from the reviewers. Finally, this work is financially supported by the faculty of engineering, Kasetsart university.

***Abstract*-The Conventional Orthogonal Frequency Division Multiplexing (OFDM) [1] transmission system uses a fixed-length Cyclic Prefix (CP) to reduce the Intersymbol Interferences (ISI) [2] and Intercarrier Interference (ICI) [3, 4] caused by channel delay under wireless environment. When the CP is less than the time delay of multipath fading channel, the efficiency of symbol decreased. When the CP equals to the time delay of multipath fading channel, the efficiency of symbol increases. In this paper, we introduce the OFDM system and then the efficiency of symbol decrement is solved using the important CP patterns in the interactive process of OFDM signals. We propose the Suitability of Cyclic Prefix (SCP) algorithm which the CP is adaptively which adjusted to the time delay in symbol duration in OFDM signal. The time delay of multipath fading channel is calculated from symbol duration method. Then the CP will be adjusted to SCP. The simulation result of SCP shown that the OFDM system can have transmit data rate higher than conventional CP.**

Keywords: **Orthogonal Frequency Division Multiplexing (OFDM), Cyclic Prefix (CP), Intercarrier Interference (ICI), Intersymbol Interferences (ISI), multipath fading channel**.

I. INTRODUCTION

As the demand for data communications rapidly increases with explosive growth of the Internet access and interactive multimedia services, broadband wireless access techniques are emerging as an attractive and economical alternative to wire-line access technologies. However, there exists fundamental challenge in high data rate transmission over a radio propagation channels. In the last few years, Orthogonal Frequency Division Multiplexing (OFDM) [1] has become very attractive for high data rate transmission over wired and wireless channels. OFDM transmits broadband signals by dividing the signals into a large number of narrowband channels to achieve resistance to such a long delay spread. In addition, a Cyclic Prefix longer than the maximum time delay is inserted between adjacent OFDM symbols, and a scheme called Cyclic Prefix is incorporated into the CP in order to completely eliminate both the intersymbol interference (ISI) [2] and the concurrently occurring intercarrier interference (ICI) [3, 4]. In the OFDM system, the CP is a well-known technique for maintaining the orthogonality between subcarriers against the multipath fading channel [3, 4] distortion in the present of multipath propagation paths whose excess delays are shorter than the CP. The intersymbol interference (ISI) occurs within the CP, and the CP is removed before decomposing an OFDM symbol into the subcarriers using a Fourier transform. However, the bit error performance is degraded in the presence of multipaths whose excess delays are longer than the CP. Because the ISI remained after the CP is removed, and the orthogonality between subcarriers is lost. The intercarrier interference (ICI) [3] also occurs. Therefore, the CP has to be long enough for an expected delay spread of the multipath fading channel, where as a shorter CP is more desirable because a long CP causes a decrease in transmission efficiency.

In this paper, we propose the suitability CP equalization OFDM transmission method. Under multipath fading channel environment, when the length of CP is longer than time delay or CP is less than the time delay, we will adjust the CP equal to the time delay. So the suitable CP length can be used to enhance bandwidth efficiency.

The rest of paper is organized as follow. In Section II, We introduce the OFDM system and propose the suitability of Cyclic-Prefix Modification. In Section III, We explain the SCP method which applied for efficiency increase of OFDM transmission. In Section IV, The result of simulation that the SCP applied to OFDM transmission is shown and compared to the conventional CP. Finally, conclusions are given in Section V.

II. OFDM SYSTEM AND THE SUITABILITY OF CYCLIC-PREFIX MODIFICATION

Figure 1 illustrates for the conventional OFDM transmission scheme. In the transmitter, a high-speed serial data stream is digitally quadrature modulated, converted to parallel low-speed modulated data streams, and fed to several traffic subcarrier channels. The modulated signals are frequency-division-multiplexed by an inverse fast Fourier transformation (IFFT) circuit which actually generates the OFDM symbol. A cyclic prefix is inserted in front of each OFDM symbol to eliminate both the intersymbol interference (ISI) and the intercarrier interference (ICI). The resulting OFDM is then converted to serial, converted into an analog by a digital-to-analog

(D/A), up-converted (U/C) to radio frequency band and transmitted in air.

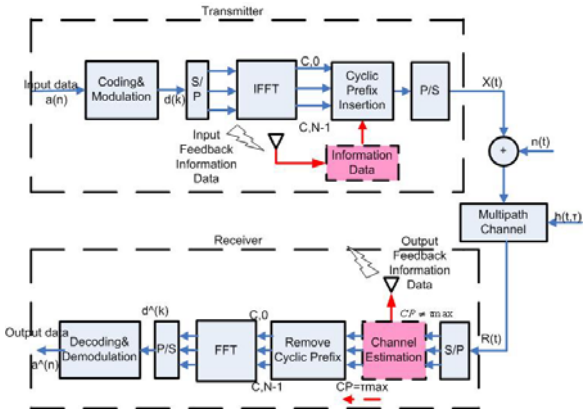

Figure1. The conventional OFDM system with proposed algorithm

After the received signal is down-converted (D/C) to lower frequency. The converted signals are sampled by an analog-to-digital (A/D) converter, converted to parallel and removed cyclic prefix. The sampled data are fed into an FFT circuit and demultiplexed as subcarrier-channel data. Finally, the data in these subcarrier-channel are demodulated by digital quadrature demodulator.

This paper proposed the SCP algorithm for OFDM system as the information data and channel estimation blocks. They are.applied into the transmitter and the receiver in Figure1. The OFDM transmission that the time delay is equal to and less than GI are shown in Figure 2a and Figure 2b respectively. The conventional method used the fix length CP. The SCP algorithm will adjust a suitable CP follow to the time delay.

The OFDM system start at the receiver to calculate the time delay from the time symbol duration. If the time delay is equal to the CP, the process in OFDM received is continued. If the time delay is not equal to the CP, the system will adjust the CP to suitable CP which calculated from the autocorrelation cyclic prefix method in channel estimation [5] block. The Cyclic Prefix method for the time symbol duration estimation will be explained in section III. Normally the guard interval is fixed to 16 points or 800 *n*s that is enough to cover the delay waves. We divide 800 *n*s to 16 parts (1part=50*n*s) for SCP points as shown Figure 3. The receiver sends SCP point data to the transmitter for a new SCP.

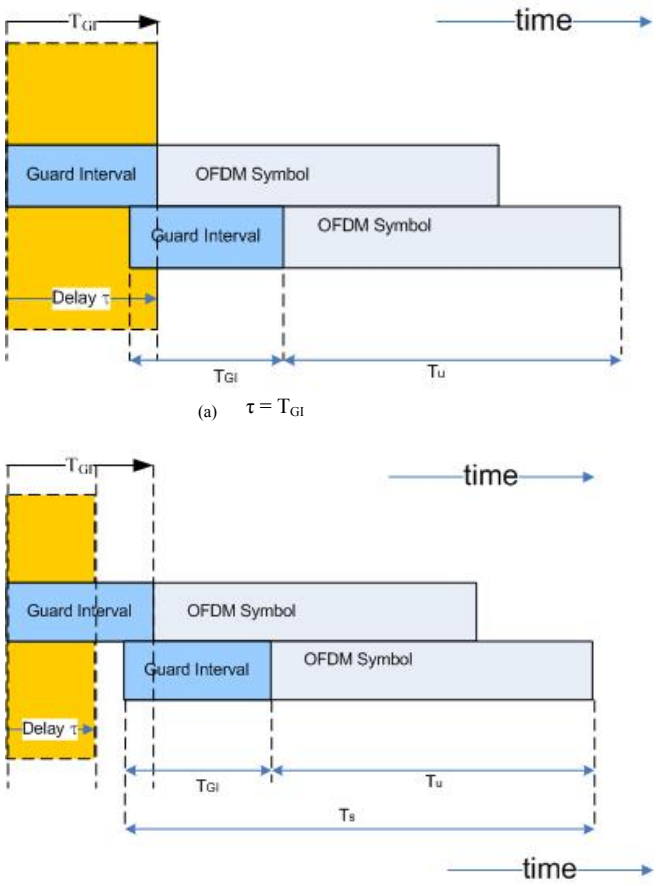

Figure2. Method with variable effective symbol duration

III. SUITABILITY OF CYCLIC-PREFIX METHOD

OFDM transmitted symbols can be expressed as a sum of single carrier modulated signals:

$$x_e(t) = \sqrt{\frac{2P}{N_c}} \sum_{k=0}^{Nc-1} \sum_{n=0}^{Nc-1} d_i(k) e^{2i\pi f_n (t-kT_s)} \cdot g(t-kT_s) \qquad (1)$$

Where f_n is the effective symbol length:

$$f_n = f_0 + n\Delta f$$

where $d_i(k)$ is the symbol sequence nth subcarrier of the ith OFDM symbol which is assumed to be centered, Nc is the number of sub-carriers, Δf is the frequency offset between carriers, f_0 is the frequency of the carrier, g(t) is the transmission pulse function and P is the average transmitting power. In Figure2, Ts = Tu +T_{GI} is the symbol duration, where Tu is the useful duration and T_{GI} is the guard interval duration. We assume to receive the complex signal:

$$r(t) = x(t)h(t) + n(t) \qquad (2)$$

where x(t) is the baseband signal of an OFDM modulation:

$$r(t) = \sqrt{\frac{2P}{N_c}} \sum_{k=0}^{Nc-1} \sum_{n=0}^{Nc-1} d_i(k) e^{2i\pi(\delta f_0 + n\Delta f)(t-t_0-kT_s)} \cdot g(t-kT_s) + n(t) \quad (3)$$

where t_0 is the time offset, δf_0 is the frequency offset and n(t) is AWGN (additive white Gaussian noise). Then we estimate the useful duration and the guard interval duration.

We compute the cyclic moment corresponding to the correlation between the signal and its conjugate version. Then the cyclic autocorrelation can be expressed by:

$$R_x(t,\tau) = E\{x(t)\cdot x^*(t-\tau)\} \quad (4)$$

and then (1) can be expressed by (5):

$$R_x(t,\tau) = \left(\frac{2P}{N_c}\right) \cdot \sum_{k,l=0}^{Nc-1} \sum_{m,n=0}^{N_c-1} E\{d_i(k)\cdot d_i^*(k)\} \cdot g(t-t_0-kT_s)\cdot g^*(t-t_0-lT_s)\cdot e^{2i\pi[(f_n+\delta f_0)(t-t_0-kT_s)]}\cdot e^{2i\pi[(f_n+\delta f_0)(t-t_0-lT_s)]} \quad (5)$$

Under the assumption that the emitted symbols are centered, we can deduce that:

$$R_x(t,\tau) = A\cdot \sum_{k=0}^{Nc-1} \sum_{n=0}^{N_c-1} g(t-t_0-kT_s)\cdot g^*(t-t_0-\tau-kT_s)\cdot e^{2i\pi[(f_n+\delta f_0)\tau]} \quad (6)$$

where $A = (2P\sigma_c^2)/Nc$ is a positive constant and σ_c^2 is the variance of emitted symbols: $\sigma_c^2 = E\{d_i(k)\cdot d_i^*(k)\}$

Besides, the summation terms can be separated, and the expression becomes:

$$R_x(t,\tau) = A\cdot \frac{\sin(\pi N_P \Delta f\tau)}{\sin(\pi\Delta f\tau)} \cdot e^{2i\pi\left[\left(f_0+\delta f_0+\frac{N_P-1}{2}\Delta f\right)\tau\right]} \sum_k g(t-t_0-kT_s) g^*(t-t_0-\tau-kT_s)\cdot \quad (7)$$

It is straightforward to see that $R_x(t,\tau)$ is time periodic with period equal to T_s:

$$R_x(t+T_s,\tau) = R_x(t,\tau)$$

The Fourier transform of R_x is discrete and is composed of peaks for the frequencies $\alpha_n = n/T_s$. For all the other frequencies, the value of transform is zero.

We compute the expression of the peaks in the Fourier transform. For $\alpha_n = n/T_s$, we have:

$$R_x^{a_n}(\tau) = \frac{1}{T_s}\int_0^{T_s} R_x(t,\tau)\cdot e^{-2i\pi a_n t}\cdot dt \quad (8)$$

Developing the expression and assume $t' = t - t_0 - kT_s$, we obtain:

$$R_x^{a_n}(\tau) = \frac{A}{T_s}\cdot e^{-2i\pi\left[\left(f_0+\delta f_0+\frac{N_P-1}{2}\Delta f\right)\tau + a_n t_0\right]} \cdot \int_{-\infty}^{+\infty} g(t')\cdot g^*(t'-\tau)\cdot e^{-2a_n t'}\cdot dt' \quad (9)$$

The term of cyclic correlation depends on the cyclic term of the pulse shape g (t). When we get the delay time from (9),we will change the SCP point follow to flowchart as shown in Figure3.

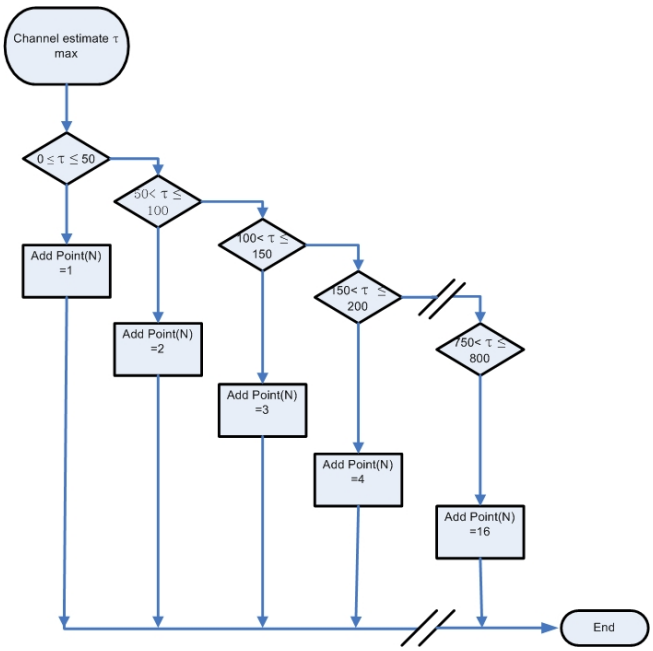

Figure3. Flowchart of Time Delay to SCP points

IV. Simulation Results

The parameters are shown in Table I. The modulation is BPSK. The data stream is converted to paralled bit stream by IFFT circuit with Number of FFT points (N) equal to 64. Each bit stream is modulated by 48 different subcarriers then combined with the extra 4 pilot signals. Totally 52 subcarriers are used. The symbol is applied with the SCP point follow to the time delay of multipath fading channel. The symbol is converted into serial bit and transmitted to the receiver.

TABLE I
Simulation Parameters

Parameters	Value
Channel Spacing	20 MHz
Number of FFT point (N)	64
Number Of Sub-carrier (M)	52
Sub-carrier Spacing (Δf)	312.5 kHz
Norminal Bandwidth ($M\Delta f$)	16.56 MHz
Symbol Duration (N)	36 (3.2μs)
Guard Interval (N)	SCP
Modulation	BPSK

From the simulation result, in the figure 4 the comparison data rate of BPSK modulation between the conventional CP and the SCP. The time delay of multipath fading channels are show between 0 - 0.8 μs. Then the SCP will be adjusted follow time delay. At the time delay equal to zero, the SCP can transmit data 11.25 Mb/s. It is better than the conventional CP still transmit data 9 Mb/s. The simulation result of SCP shows that the OFDM system can transmit data rate higher than conventional CP.

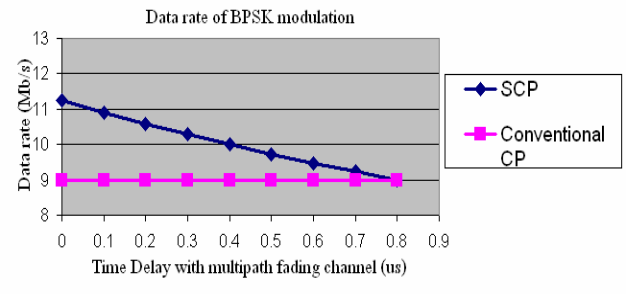

Figure4.Comparison of Data rate for Conventional CP and SCP

V.CONCLUSIONS

We propose the Suitability of Cyclic-Prefix (SCP) algorithm for OFDM transmission The OFDM system at the receiver to calculate the time delay from the symbol duration and system choose CP to suitable CP follow the time delay of multipath fading channel. Then receiver sends SCP point data to the transmitter for a new SCP. Simulation result the OFDM system with applied SCP can transmit data rate higher than conventional CP to 2.25Mb/s. This method can eliminate the time delay of multipath fading channel. The OFDM system with applied SCP can save time for data transmission and the system can be used beneficially.

***Abstract* —The aims of this paper are to study the impact of directivity to the performance of an Engen's six-port reflectometer (SPR) and propose a simple technique based on inductive compensated coupled lines for an SPR design. Comparison of the performances of the SPR with compensated and uncompensated coupler designs is made at 2.4 GHz frequency. Based on the calculation data, the SPR with an inductive compensated coupler achieves small measurement error which is less than 5%.**

I. INTRODUCTION

The idea of using a six-port structure to determine the phase of a microwave signal was first presented in 1964 by Cohn and Weinhouse [1]. In fact, a six-port network can be considered simply as a system of one input, one output, and four power detector ports. With a deterministic signal applying at the input port, the unknown impedance at the output port can be determined from the DC powers measured at the detector ports [2]. The unknown impedance is obtained by solving a set of four characteristic equations, which is related to network parameters from these DC powers. In practice, a calibration procedure would be applied to determine the network parameters as they are sensitive to aging, atmosphere, and nonideality of the devices. After calibration is done, the power measurement will be performed. The three power ratio equations will be situated from the DC power reading and subsequently resort to derive both real and imaginary values of the unknown impedance. Therefore the direct application of a six-port structure, for example a network analyzer or an impedance reflectometer, is for complex impedance measurement. There are also some indirect applications such as a modern digital receiver, a permittivity measurement system, to name a few [2]-[4].

For complex impedance measurement application, several six-port design junctions were proposed [5]-[6]. It is well known that, apart from calibration errors, the measurement accuracy of a six-port reflectrometer (SPR) is governed by the error magnitude of the DC power measurement. Numerous effects; i.e. thermal noise, zero drift, network configuration; can easily harm the measurement accuracy [7]. The scope of this paper will focus on the network configuration solely.

It was already stated, without proofing, that the six-port configuration provides the accurate results when the phase difference of the "q-points" are 120^{o} at the operating frequency. In fact the q-points are the center of the circles obtained from the three power ratio equations already mentioned. There are various network configurations but only the structures proposed by C. Engen [8] are practicable for complex measurement application as its simplicity. The basic building blocks composed in the *preferred* structures are quadrature coupler, hybrid coupler, power divider, and directional coupler. Among these, a directional coupler is atleast included in the Engen's networks.

In fact directivity in directional coupler does impact to measurement accuracy. Such issue was also claimed by Engen without proofing. Thus, in this paper the relation between measurement error of the SPR proposed by Engen and the directivity of the applied directional coupler is exhaustively studied. The accuracy and the "q-points" distribution characteristic will be investigated for different unknown impedances and coupler directivities in Section 2. The benefit of the paper is to provide design criteria for directional coupler in Engen's SPR. Section 3 presents the feasibility of applying inductively compensated coupler in the SPR. Numerical results of the SPR operated at 900 MHz are presented for the measurement error obtained from the proposed technique. The paper is finally concluded in Section 4.

II. IMPACT OF DIRECTIVITY TO MEASUREMENT ERROR AND Q-POINTS DISTRIBUTION

A. Engen's six-port reflectometer

A six-port reflectometer (SPR) with nearly ideal "q-points" distribution shown in Fig. 1 includes only four quadrature hybrid couplers (Q) and one directional coupler (C). The ports P_3-P_6 are the power detector ports where P_1 and P_2 are the

input and output ports, respectively. The unknown load is connected at port 2 while port 1 connects to a sinusoidal source of testing frequency f_0 Quadrature hybrids in Fig. 1 can be simply implemented by either branch-line coupler or parallel-coupled lines. For the directional coupler, parallel-coupled lines highly suit for implementing in term of practical viewpoint.

As stated, a complex impedance can be determined by solving three power ratio equation set related to the "q-point" positions [9] as shown:-

$$\frac{P_i}{P_3} = K_i \left|\Gamma'_L - q_i\right|^2, \mathrm{i} = 4,5,6 \qquad (1)$$

where P_i is the power reading from the detector at port i, Γ'_L is the estimated reflection coefficient of an unknown load, K_i and q_i are constants related to the network parameters in Fig. 1 which are obtained from the calibration procedure.

The Γ'_L can be determined by solving the equation set in (1). The measurement accuracy which can be described with a percentage error (e) then can be defined as:-

$$\varepsilon = \left|\frac{\Gamma_L - \Gamma'_L}{\Gamma_L}\right| \times 100 \qquad (2)$$

where Γ_L is the exact reflection coefficient of the load.

Q-points distribution characteristic of the SPR is related to the coupler directivity. This is quite obvious since each q-point in the SPR in Fig. 1 is related to the S-parameter of the circuit as shown [10]

$$q_i = \frac{S_{i2} - (S_{i1}S_{22})/S_{21}}{S_{i1}/S_{21}} \qquad (3)$$

Eq (3) will be applied to plot the "q-points" distribution characteristic in a complex plane. If all the devices used in Fig. 2 are ideal and a 6-dB ideal directional coupler is used, from (2), the magnitudes of all "q-points" are equal and their phase differences are 90°, 135° and 135°.

B. Impacts of finite directivity on measurement errors and q-points distribution

Here we assume that all components used in Fig. 2 except the directional coupler is ideal. An ideal quadrature hybrid coupler shown in Fig. 2 a) can be mathematically modeled as shown

$$[S]_Q = \frac{-1}{\sqrt{2}}\begin{bmatrix} 0 & j & 1 & 0 \\ j & 0 & 0 & 1 \\ 1 & 0 & 0 & j \\ 0 & 1 & j & 0 \end{bmatrix} \qquad (4)$$

A directional coupler shown in Fig. 2 b) can be mathematically modeled as shown:-

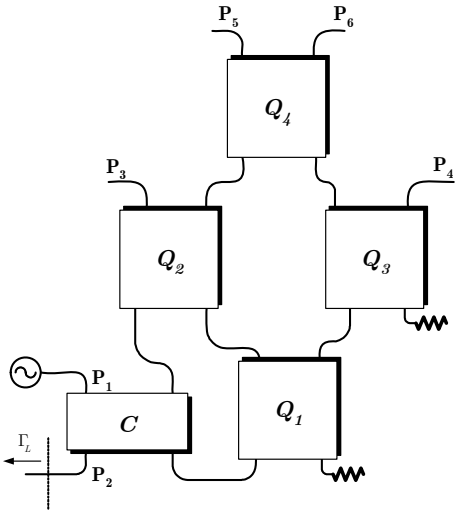

Fig. 1. Schematic diagram of the studied six-port junction [8].

$$[S]_C = \begin{bmatrix} a & C & I & -j\sqrt{1-C^2} \\ C & a & -j\sqrt{1-C^2} & I \\ I & -j\sqrt{1-C^2} & a & C \\ -j\sqrt{1-C^2} & I & C & a \end{bmatrix} \qquad (5)$$

where a are all ports return loss, C is the coupling factor and I is the Isolation coefficient.

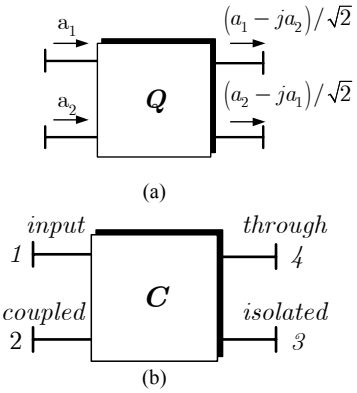

Fig. 2: a) Quadrature hybrid (Q) and b) directional couplers (C) [9].

$$D(dB) = C(dB) - I(dB) \qquad (6)$$

Applying the model from (3)-(5) in Fig. 1. The S-parameter of the SPR with finite directivity is obtained. The error magnitude and "q-points" distribution of the SPR designed based on a finite directivity coupler are calculated from (2) and (3), respectively.

Fig. 3 shows a percentage error of the SPR for different coupler's directivities, from 10 to 60 dB. The results were calculated for four different resistive terminations, i.e. R_L =5, 25, 50, and 100 Ω. The error obtained from the SPR estimation is increased when the coupler directivity decreases.

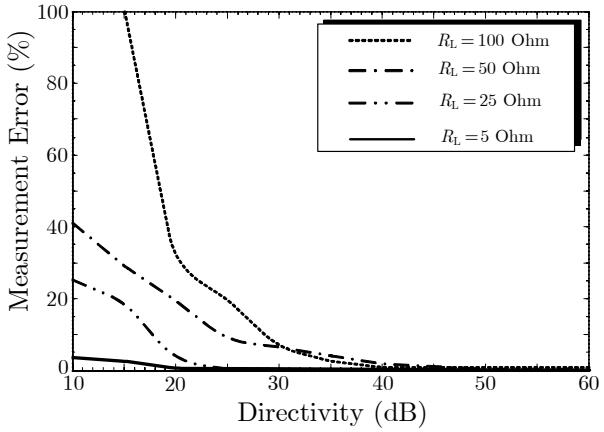

Fig. 3: Percentage measurement error of the SPR for different directivities.

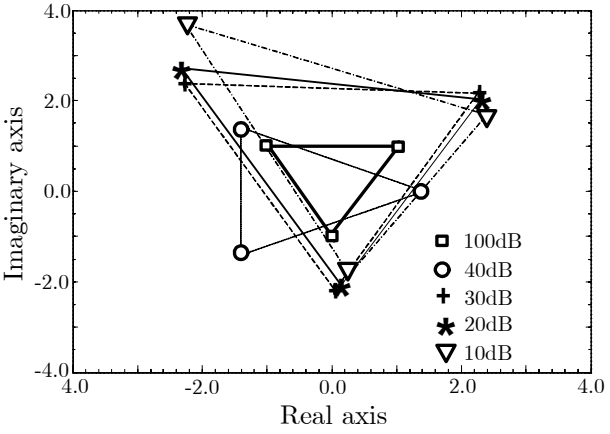

Fig. 4. Q-points distribution with different directivities.

It is shown that a directional coupler which greater than 40-dB directivity is needed to achieve less than 2% error.

The "q-points" distributions of the SPR for different directivities are shown in Fig. 4. The investigation was performed for five different cases, 10-, 20-, 30-, 40-, and 100-dB directivity. The "q-points" distribution of the 100-dB case, which can be considered as a perfect "q-points" distribution", is located at the positions for infinite directivity case. The "q-points" distribution starts to deviate from the perfect distribution when the directivity reduces.

III. Applying Inductively Compensated Coupled Lines to Six-port Reflectometer

A. Quadruply-Inductive Compensated Coupled Lines

Various compensated directional coupler capable to apply for SPR design exist but inductive compensated coupler [11] is chosen as its simple design and implementation. The singly and doubly-inductive compensated parallel-coupled lines, which were recently proposed [12] are not suitable for the SPR which requires symmetrical directional coupler. Rather a quadrupled inductive-compensated coupler shown in Fig. 5 is proposed for SPR design. Four equal inductors denoted by L_Q

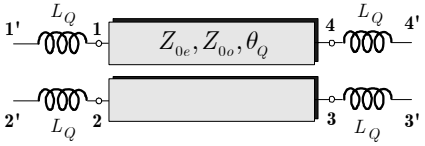

Fig. 5. Quadruply-inductive compensated parallel-coupled lines.

are connected in series at all coupled lines' ports. The uncompensated coupled lines ports are denoted by port 1-4 where the ports of the inductive-compensated coupled lines are labeled as port 1'- 4'. The isolation coefficient (S_{31}), in term of coupler electrical parameters (Z_0, Z_{0e}, Z_{0o}, ε_{effe}, ε_{effo}), is evaluated by terminating port 2', 3', and 4' with the characteristic impedances of the lines Z_0, while port 1' is terminated with voltage source with the output impedance Z_0. The maximum directivity at the operating frequency is occurred when the signal transmission of port 1 and 3 is null, i.e. $S_{31}(f) = 0$. By applying this condition, L_Q can be enumerated form [11]:-

$$L_Q = \frac{1}{2\pi f_0}\mathrm{Im}\left\{\frac{Z_0^2\left(\cosh\theta_e - \cosh\theta_o - Z_0 Z_A\right) - Z_B}{Z_A}\right\} \tag{7}$$

where $Z_A = Z_{0e}\sinh\theta_o - Z_{0o}\sinh\theta_e$ and

$$Z_B = \sqrt{Z_0^2\left(Z_{0e}^2 + Z_{0o}^2\right)\sinh\theta_e\sinh\theta_o - 2Z_0^2\left(\cosh\theta_e\cosh\theta_o - 1\right)}$$

Equation (7) offers a closed-form expression to design the compensating inductances for achieving high directivity at the center frequency f_0. However, the compensating inductances retard phase of the propagated signal, the zero-isolation frequency is shifted to frequency which is lower than the original frequency. Similar to the other lumped compensation techniques, the center frequency can be simply shifted back to original frequency by modifying the electrical length of the compensated parallel-coupled line as shown:-

$$\theta_Q = \cot^{-1}\left(\frac{4\pi f_0 L_Q - Z_{0o}\cot\theta_o}{2Z_{0e}}\right) \tag{8}$$

Then, the design equations for quadruply-inductive compensated microstrip coupled lines i.e. L_s and θ_f were calculated from (7) and (8) respectively.

B. Inductive Compensated Coupled Lines based SPR

A 6-dB nductive-compensated microstrip parallel-coupled lines operating at f_o of 2.4 GHz on RF60-0600 microwave substrate with electrical parameters (Z_{0e} = 86.74 Ω, Z_{0o} = 28.82 Ω, ε_{effe} = 4.502 and ε_{effo} = 3.303) were designed and simulated. The compensation inductors (L_Q) and the shorten electrical lengths (θ_Q) were calculated from (3) and (4), which are 0.7 nH and 0.47π, respectively.

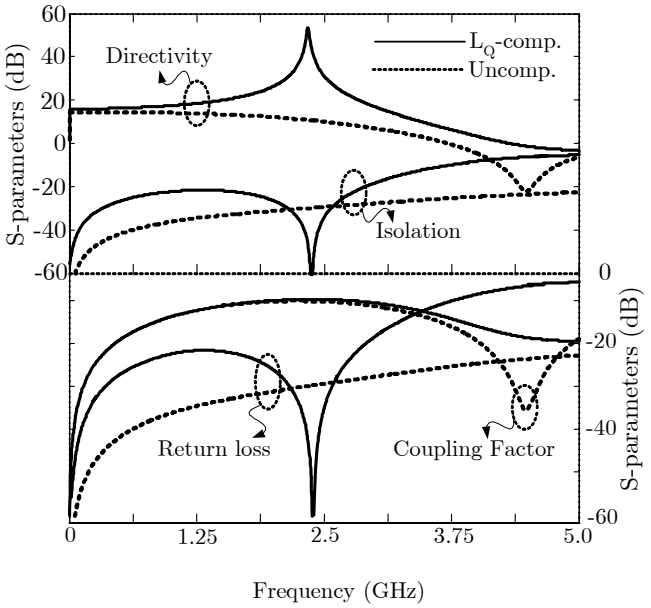

Fig. 6. Simulated results of compensated coupler

The coupled lines circuit based simulation results are shown in Fig. 6. It is shown that at f_0, the design provides directivity of more than 46 dB. To prove the validity of the proposed technique, a 6-dB uncompensated coupler was designed. The simulated result of the obtained directivity of the uncompensated coupler at 2.4 GHz is 16 dB. The designs were applied for coupled lines in the SPR shown in Fig. 1. Simulating the measuring of complex load Z_L = 25 +j30 Ω with uncompensated (13.8 dB) and quadruply compensated (46.2 dB) cases directivity. The q-points values and distribution of these cases were shown in table I, II and Fig. 7. These results are corresponded with ideal cases simulation.

Table I Simulated Q-values of 2.4 GHz SPR

D	Q_3		Q_5		Q_6	
(dB)	Re{}	Im{}	Re{}	Im{}	Re{}	Im{}
13.8	0.260	-1.82	2.390	1.680	-2.250	3.690
46.2	0.007	-0.97	1.013	0.998	-1.013	1.027

Table II Simulated measure impedances and errors of 2.4 GHz SPR

D (dB)	Real (Ω)	Imaginary(Ω)	% error
13.8 dB	20.81	49.63	37.81
46.2 dB	26.12	31.53	4.84

IV. CONCLUSION

A studied of the relation between microstrip coupled lines' directivity and measurement error of six-port reflectometer is presented. The error obtained from the SPR estimation is increased when the coupler directivities were decreased. From the investigation, it is shown that a directional coupler which greater than 40-dB directivity is needed to achieve less than

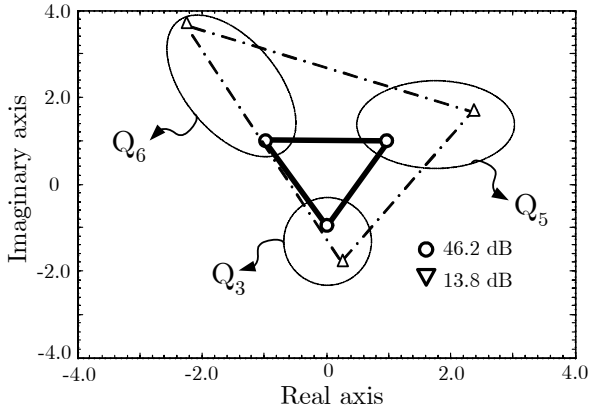

Fig. 7. Q-points distribution with 13.8 dB, and 46.2 dB directivities of 2.4 GHz microstrip SPR.

2% error for real loads and less than 5% for complex load. Design procedures for the compensation inductors have been provided to enhance coupled lines directivity. More important, the closed- form expressions for determining the compensation inductor values and coupled-line parameters are given to facilitate the design task considerably.

Suranaree University of Technology, Nakhon Ratchasima, Thailand
E-mail: rangsan@sut.ac.th

***Abstract*-This paper presents the impedance analysis of a shorted-end curved dipole antenna on a square reflector plane. The current distribution of the curved dipole antenna can be solved numerically using the Method of Moment (MoM). A system of linear equations is generated to form matrix model and the inversion of this matrix can realize the current distributions, which are used to determine the impedance characteristics of this antenna. These simulation results have been validated with measurements on a fabricated prototype. The proposed antenna with simple structure is very suitable for UHF TV broadcasting station.**

I. INTRODUCTION

Broadcasting system has been extensively and continuously used for distributing information over wide range of the service area. The antenna applied for the broadcasting station of the ultra high frequency television (UHF TV) requires either unidirectional or omnidirectional beam with sufficient gain, high power handling, and bandwidth of each channel is 6 MHz [1]. Moreover, the antenna should possess physically strong structure, easy fabrication and cost effectiveness.

Most manufacturers offer configurations that can be used to broadcast a wide variety of azimuth and elevation patterns at either low or high power with their simple feeding system, low windload, and ability to be side- or top-mounted. Conventionally, the popular antenna utilized for this purpose is the UHF antenna panel system [2], which is one type of broadcasting antennas that contains horizontally polarized wire/patch dipoles as an array arrangement. To achieve omnidirectional pattern, however, the panel system must be placed around the tower at least four panels because the beamwidth of each panel is not much wide. In addition, the structure of conventional panel system is probably complex and required the fully feed system.

From these aforementioned literatures of the conventional UHF TV broadcasting antennas, it is obvious that the antenna which possesses simple structure and simple feeding system is desirable. An antenna made of curved-wire dipole, which the both ends are shorted on the metallic reflector plane, is an attractive one since the structure and feed system is very simple. Moreover, the beamwidth of curved-wire dipole is larger than straight dipole.

Most of substantial works related to the shaped or curved dipole structures. Krishnan *et al.* [3] presented a V-shaped wire-loop with a butterfly-like structure. The elliptically polarized radiation of S-shaped dipole antenna was presented by Elkamchouchi and Nasr [4]. Besides these, Dubost [5] presented the radiation impedance and bandwidth of a short-circuited dipole parallel to a perfect reflector plane. As far as we know, there is no information about the curved dipole that the both ends are shorted on a metallic reflector plane, which is necessary for the structure that requires the simple fabrication, simple feeder, and high power handling. Since impedance is the important characteristic that determines the efficiency of the antenna. Therefore, this paper focuses on the impedance of a shorted-ends curved dipole. Theoretical background of this antenna will be determined by using Method of Moments (MoM). The Pocklington's integral equations for total filed are first formulated and are subsequently solved by using Method of Moments to determine the unknown current densities. Finally, the input impedance of the antenna at the center feed will be determined and validated by measurement.

II. THEORY

The structure of a shorted-end curved dipole antenna is composed of a curved-wire dipole, which their both ends are short-circuited on a metallic reflector plane as shown in Fig.1. The curved-wire dipole of the length L, the wire radius b, and the curved radius a is aligned along ϕ-direction at which the feed center of this curved dipole is located at $\phi = \pi/2$. The dimension of a square reflector plane of the width W is one wavelength as shown in Fig.2.

The current distribution of the shorted-end curved dipole antenna can be obtained by using the Pocklington's integral equation and solved numerically using the method of moments. The point-matching technique is then used to satisfy the integral equation at discrete points on the axis of curved dipole rather than attempting to satisfy this equation everywhere on its surface [6]-[7]. Thus, a system of linear algebraic equations is generated to form the matrix model and the inversion of this matrix can realize the current distribution on the curved dipole, which is used to determine the input impedance of this proposed antenna.

In this work, the Pocklington's integral equation for the total field calculation, which are generated by an electric current source radiating in an unbounded free space [8], which can be written in the form of

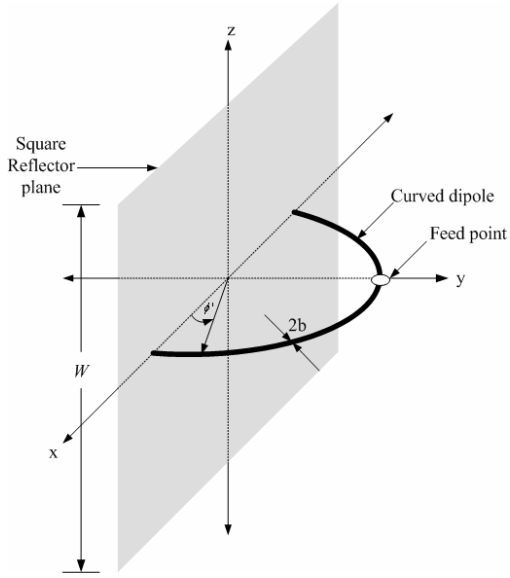

Figure 1. Geometry of the shorted-end curved dipole on a reflector plane.

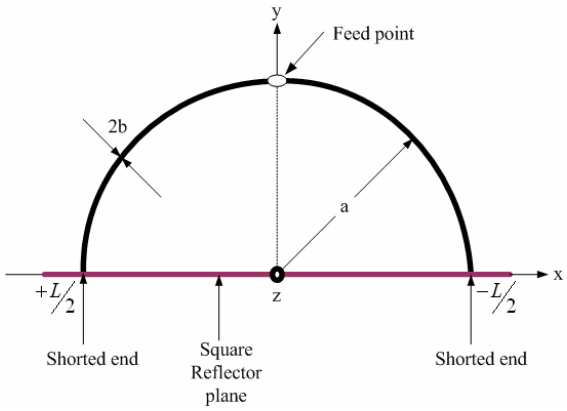

Figure 2. Analysis model of the shorted-end curved dipole on a reflector plane.

$$\int_{-L/2}^{+L/2} I_n\left(\phi'\right)\left(\frac{\partial^2}{\partial_\phi^2}+k^2\right)\frac{e^{-jkR}}{R}d\phi' \;=\; j4\pi\omega\varepsilon_0 E_\phi\,, \tag{1}$$

where E_ϕ is the radiated field due to the current $I_n\left(\phi'\right)$. Resulting from a source field E_ϕ, that could be caused by voltage applied at the antenna feed point or incident plane wave $E_{\phi'}^i$. Here ϕ' and ϕ are the source location variable and the observation location variable, respectively, and R is the distance from any one point on the source to the observation point. For small diameter wires, the current on element can be approximated by a finite series of odd-order even modes [7]. Thus, the current on the element can be written as a Fourier series expansion of the form:

$$I_n\left(\phi'\right)=\sum_{m=1}^{M} I_{nm}\,g_n\left(\phi'\right)\,, \tag{2}$$

where $g_n\left(\phi'\right)$ is entire domain basis functions [8], which is given by

$$g_n\left(\phi'\right)=\cos\left[\frac{\left(2m-1\right)\pi\phi_n'}{L_n}\right],\;\; 0\le\phi_n'\le\pi, \tag{3}$$

where L_n is the corresponding length of the n element.

After some rigorous derivations and using entire domain functions with Pocklington's integral equation, the integral equation for each element of the proposed antenna can be written as [8]

$$E_\phi^t=\frac{1}{j4\pi\omega\varepsilon_0}\sum_{m=1}^{M} I_{nm}\left\{\left(-1\right)^{m+1}\frac{\left(2m-1\right)\pi}{L_n}G_2\left(\rho,\rho',\phi,\phi'/z,\frac{L_n}{2}\right)\right.$$
$$\left.+\left[k^2-\frac{\left(2m-1\right)^2\pi^2}{L_n^2}\right]\times\int_0^{L_n/2} G_2\left(\rho,\rho',\phi,\phi'/z,\phi_n'\right)\cos\left[\frac{\left(2m-1\right)\pi\phi_n'}{L_n}\right]d\phi_n'\right\}, \tag{4}$$

where I_{nm} represents the unknown current coefficient of mode m on element n. Because of the proposed antenna comprises two elements such as driven and reflector elements. Therefore, n = 2 is the total number of elements. Green's functions is given as

$$G_2\left(\rho,\rho',\phi,\phi'/z,\phi_n'\right)=\frac{e^{-jkR_-}}{R_-}+\frac{e^{-jkR_+}}{R_+}\,, \tag{5}$$

where $R_\pm$ represents the distance from each wire radius to the center of any other wire which can be shown by

$$R_\pm=\sqrt{\left(a-a'\right)^2+\left(z-z'\right)^2+b^2+\left(\phi\pm\phi'\right)^2}\,. \tag{6}$$

From (4), in according with referred to as point-matching method, in matrix form can be expressed as

$$\left[V_m\right]=\left[Z_{nm}\right]\left[I_{nm}\right]\,, \tag{7}$$

where

$$Z_{mn}\;=\;\left\{\left(-1\right)^{m+1}\frac{\left(2m-1\right)\pi}{L_n}G_2\left(\rho,\rho',\phi,\phi'/z,\frac{L_n}{2}\right)+\left[k^2-\frac{\left(2m-1\right)^2\pi^2}{L_n^2}\right]\right.$$
$$\left.\times\int_0^{L_n/2} G_2\left(\rho,\rho',\phi,\phi'/z,\phi_n'\right)\cos\left[\frac{\left(2m-1\right)\pi\phi_n'}{L_n}\right]d\phi_n'\right\} \tag{8}$$

and

$$V_m\;=\;4\pi\varepsilon_0\,. \tag{9}$$

Finally, the unknown coefficients I_{nm} can be solved from the matrix model in (7) by using a number of matrix inversion techniques.

III. NUMERICAL RESULTS

For illustration, the shorted-end curved dipole antenna was designed to operate at the center frequency of 470 MHz. From the preliminary study it was found that, at this operating frequency, the radius of curvature *a* and the wire radius *b* should be 10.15 cm and 0.005 λ, respectively, so that the good matching condition and the proper gain of this antenna could be obtained. Computations for this proposed antenna have been made using the formulas of previous section. For the current itself, convergence was about 5.5 percent change in going from 30 to 50 segments. In our case, 40 segments for a half-wave length of antenna will give accurate results as shown in Fig.3. It is found that the appropriate length of this curved dipole should be half-wavelength due to the current magnitude at the both ends is zero.

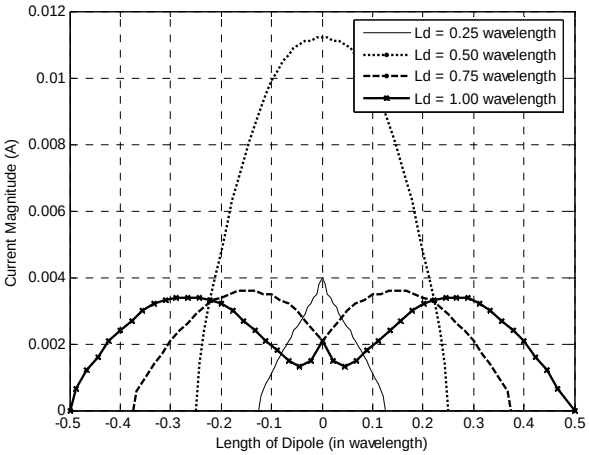

Figure3. Current distribution of curved dipole.

The length of curved dipole is the important parameter to characterize the impedance characteristics. The curved dipole length is varied from 0.25λ to 0.75λ while other parameters are fixed. The numerical results of the input resistance and reactance of a shorted-end curved dipole as a function of the frequency are illustrated in Figs. 4 and 5, respectively. From Fig. 4, it is obvious that the larger the length, the larger the resistance and the reactance. For the resonant frequency observed from the zero reactance, it can be seen that the resonant frequency will be higher when the dipole length is shortened. The resonant frequency of 470 MHz is realized when cavity length is around 0.5λ.

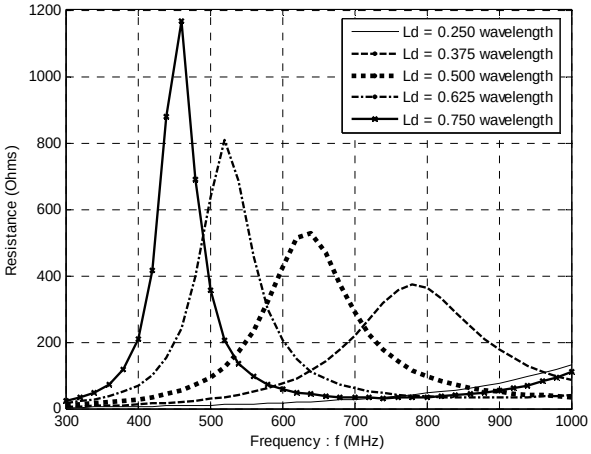

Figure 4. Input impedance characteristic of curved dipole.

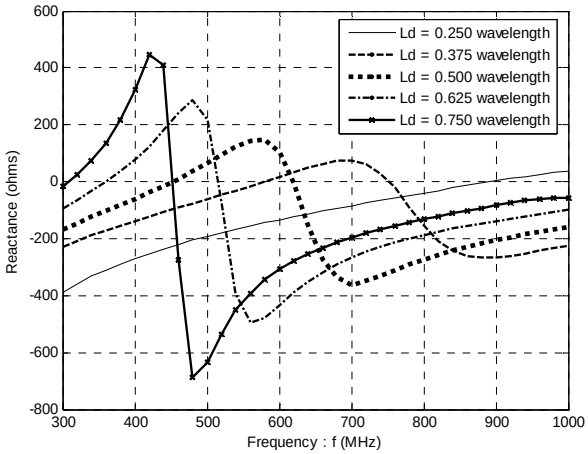

Figure 5. Input impedance characteristic of curved dipole.

IV. EXPERIMENTAL RESULTS

To verify the theoretical calculation, the curved dipole, which the both ends are short-circuited on the reflector plane is fabricated and the input impedance is measured by using an HP8720C Network Analyzer. The prototype of the fabricated antenna is shown in Fig. 6. To achieve impedance matching, the $\lambda/4$ coaxial balun (1:1) is mounted at the center gap of curved dipole to balance inherently unbalanced system. The measured results are superimposed as dashed line in Figs. 7 and 8. It should be pointed out that the good agreement between theory and experiment can be observed that the input impedance is around 50 Ω at the operating frequency of 470 MHz.

Figure 6. Photograph of the prototype of the shorted-end curved dipole.

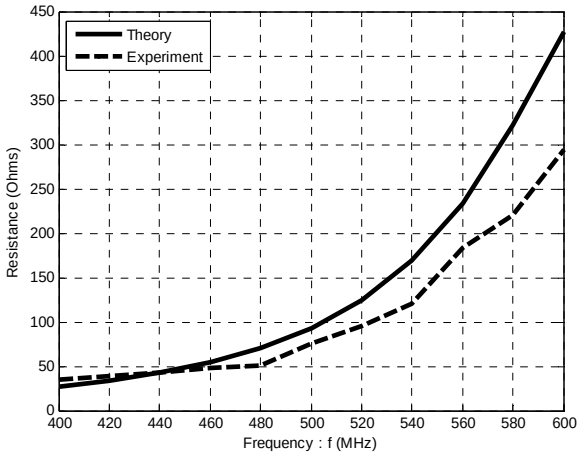

Figure 7. Input resistance of shorted-end curved dipole.

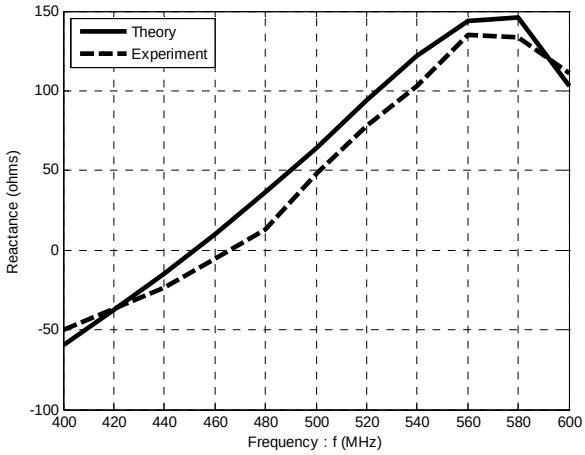

Figure 8. Input reactance of shorted-end curved dipole.

V. CONCLUSION

Input impedance is an important characteristic that affects the antenna efficiency. It must be well investigated so that the matched antenna can be designed. This paper focuses on the input impedance characteristics of a so-called shorted-end curved dipole on a reflector plane. This antenna is developed to be an UHF TV broadcasting antenna due to its simple structure and simple feeding system. In order to investigate input impedance of this antenna, the straightforward procedure is applied. Starting from formulations of integral equations of the structure based on the Pocklington's integral equation. The entire domain basis function is used in the Method of Moments to solve the electric current density on the curved dipole. The input impedance can be found from this current subsequently. From the numerical results, the frequency response of input impedance can be investigated, which is very useful to find the optimum matching condition by simply adjusting the length of curved dipole.

A Finite Element Method with Polygonal Elements for Analyzing a Band Gap Characteristic of Square Lattice Photonic Crystals

Eny Sukani Rahayu and Tuptim Angkaew
Electrical Engineering Department, Chulalongkorn University
Bangkok, Thailand

***Abstract*–Finite element method (FEM) with polygonal elements employing the Wachspress shape functions to analyze the band gap characteristic of two-dimensional photonic crystals (2D PCs) is presented in this paper. The performance of the method compared with which of the linear triangular FEM is provided by showing the error calculation in order to observe the accuracy. The flexibility of meshing using polygonal elements with Wachspress shape function as the interpolation function is also presented. The results compared with those from linear triangular FEM show better accuracy than the linear triangular FEM with less number of unknowns.**

***Index Terms*–Polygonal elements, FEM, Wachspress shape function, 2D PCs and a band gap characteristic.**

I. INTRODUCTION

Photonic crystals (PCs) are periodic dielectric structures which can exhibit a photonic band gap (PBG) characteristic, where optical wave with frequency ranged in the band gap cannot propagate through the structures. In other words, the optical wave with that certain range of frequency is reflected by PCs [1]. This main property of PCs where these materials can control the propagation of optical waves is unique and gives great motivations in modifying and designing them to be high performance devices such as photonic integrated circuit (PIC) to support the next generation PICs in nanotechnology world [2,3,9]. Large contributions of two-dimensional (2D) PCs yield some devices such as lasers, couplers and most of optical devices used in optical networks [2,9]. One of the examples of 2D PCs is a square lattice PCs shown in Fig.1.

PC-based devices works at an operational frequency referred back to the band gap characteristic of such PC for a special purpose and in order to reduce the loss in the devices. Since the band gap is the most important property of PCs, the analysis of the band gap characteristic using improved numerical tools is advantageous as a starting point.

The band gap characteristic of such PCs depends on the geometry of the PC structures such as types of lattices, a filling ratio, and specifications of used materials. The geometry of the structures varies depending on the improved design of PCs and on the imperfect fabrication process. Therefore, the improvement in numerical tools to calculate the band gap characteristic is quite necessary to be investigated.

Several methods have been proposed and some of them are still used so far such as the famous plane wave expansion method (PWE) [4], finite difference time domain method (FDTD) [5], compact finite difference frequency domain method (FDFD) [7] and finite element method (FEM) [3,6,8]. The most flexible method in the application for any arbitrary shape and geometry structure of the calculation domain is the FEM so this method has been more suitable for analyzing even the real condition of PCs where there is a possibility of a non-ideal geometry of the structure or a deformation on the construction of PCs due to an imperfect fabrication process. The PWE will not be able to model such structures efficiently because the PWE can only model the ideal periodic dielectric structures while the two other methods, FDFD and FDTD are less flexible and less effective in modeling an arbitrary and curved-shape calculation domain than the FEM due to the grid based discretization [5,7].

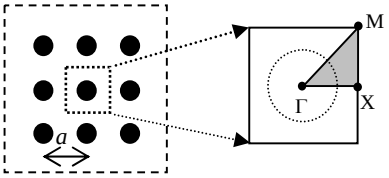

Figure 1. A square lattice PC shown with the first (zoomed area) and the irreducible (shaded area) Brillouin zone.

The FEM in previous works are formulated by incorporating Bloch theorem in the governing equations of TE and TM modes, which results in complicate FEM formulation. Recently, the 4th order finite difference formulation formulated directly from governing equations and employing periodic boundary conditions has been reported [7]. This finite difference formulation is straightforward and gives good computed results in numerical examples, but its method is not effective for the case of curved structure modeling. In this paper, the FEM for analyzing 2-dimensional PCs directly formulated from governing equations with PBCs are proposed to provide a straightforward FEM formulation for analysis band gap characteristic of 2D PCs using the polygonal FEM.

The FEM, which is known not a memory consuming numerical tool due to the sparse matrices, is such a tool used to find the approximate solutions of a boundary value problem

[3,8,12-14] which is imposed to the analyzed system. The system of 2D PCs is common to be discretizised over its domain of calculation using triangular elements as efficient shapes in modeling and simple interpolation function based on the barycentric coordinate [11,15,17]. Recently there is an improvement in meshing using generalized irregular polygonal elements called a polygonal FEM [12,16,18,19]. This work will implement polygonal FEM to calculate the band gap characteristic as a modified FEM. It is expected to be more efficient, effective and to provide a higher accuracy than the previous method in analysis of any arbitrary design of 2D PCs using the Wachspress shape function in the form of a rational basis function based on an area calculation [12,15,16]. Fig.2 shows the application of polygonal element meshes compared with the triangulation over the domain.

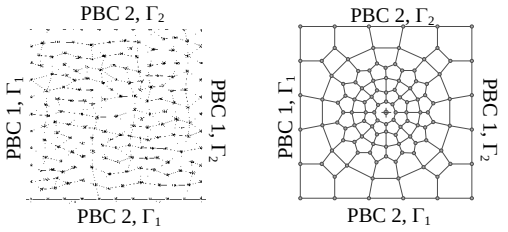

Figure 2. Samples of meshes on the same domain with triangular (left side) and polygonal (right side) elements shown with the imposed PBCs.

This paper is organized as follows. In section II, the polygonal finite element methods for analyzing the band gap characteristic is explained together with the Wachspress shape function used as the interpolation function for generalized polygonal elements. Section III shows the numerical results by comparing the approximation errors of band gap characteristic calculations between which from the linear triangular FEM and the polygonal FEM. Finally, section IV provides the conclusion of the work.

II. POLYGONAL FINITE ELEMENT METHOD

A. Governing Equations for TE and TM waves in 2D PCs

To calculate the band gap characteristic, the four Maxwell's equations are employed as basic equations. The medium of PCs is assumed to be lossless, isotropic and non-magnetic. The 2D PCs is a periodic dielectric structure, which is uniform along z-axis of coordinates system. The wave equations deriving from Maxwell's equations can be divided into 2 independent eigensystem equations, named as TE and TM modes. In TM modes, the electric field is polarized in *z*-direction while in TE mode, the magnetic field is polarized in *z*-direction. The general governing equation for both polarizations is expressed in (1) as follows

$$-\nabla \cdot p(x,y)\nabla u(x,y) = \frac{\omega^2}{c^2} q(x,y)u(x,y) \tag{1}$$

For TM mode, an unknown solution $u(x,y) = E_z(x,y)$ and constants $p(x,y)$ and $q(x,y)$ are equal to μ_r^{-1} and ε_r, respectively while for TE mode, $u(x,y) = H_z(x,y)$, $p(x,y) = \varepsilon_r^{-1}$ and $q(x,y) = \mu_r$. Here, ε_r is a relative permittivity of the medium while a relative permeability of the medium μ_r =1 for non-magnetic material, ω denotes the angular frequency of optical wave, and c is the speed of light in vacuum. The eigenvalue of the eigensystem equation in (1) is a resonant frequency of the PCs for a defined wave vector. Equation (1) is used in FEM formulation along with PBCs.

These boundary conditions employs the Bloch's function in order to model the periodic structure where the wave vectors are included. The wave vectors used as the input values are taken from the edges of the irreducible Brillouin zone of the unit cell of square lattice PCs determined by Weigner-Seitz cell algorithm [10] where the periodicity occurs. The approximate solution of FEM formulation is calculated for each sampled wave vector until the band gap characteristic is obtained for all the possible wave vectors.

The unit cell used as the calculation domain is the first Brillouin zone of square lattice PCs with a dielectric rod surrounded by an air medium due to the simple geometry. Fig.1 illustrates the square lattice PCs with the unit cell and the irreducible Brillouin zone with the suitable PBCs are shown in (2) for PBC 1 and (3) for PBC 2 as illustrated in Fig.2 based on [7]

$$u(x+a,y)|_{\Gamma_2} = e^{-jk_x a} u(x,y)|_{\Gamma_1} \tag{2}$$

$$u(x,y+a)|_{\Gamma_2} = e^{-jk_y a} u(x,y)|_{\Gamma_1} \tag{3}$$

where here u is an unknown solution on the boundary of the domain at edges Γ_1 or Γ_2 as shown in Fig.2. Symbol a denotes a length of periodicity of the square lattice points as shown in Fig.1 while k_x and k_y are particular wave vectors in x and y direction, respectively defined from the irreducible Brillouin zone as shown in Fig.1.

The unit cell domain is discretizised by finite elements. The linear unstructured triangulation in Fig.2 covers the curved domain sufficiently. However, the polygonal meshes are shown to have varied element shapes where the different n-gon elements can be conformed together by choosing a suitable interpolation function due to the linearity on the boundary so that the greater flexibility in meshing can be accomplished.

B. Wachspress shape functions

The main difference between triangular FEM and the polygonal FEM is the interpolation function. The Wachspress shape function is chosen as which for generalized convex polygon element which have properties explained in [12,15,17] where the construction is based on barycentric coordinate concept as well as the one for triangular elements.

The general shape function N_i^e in FEM is built to approximate the unknown field u within an element e using an expansion in (4).

$$\bar{u}^e = \sum_{i=1}^{n} N_i^e u_i^e \tag{4}$$

The Wachspress shape function used in (4) is formulated by (5)

$$N_i^e = \frac{\omega_i^e}{\sum_{j=1}^{n} \omega_j^e}; \text{ for } i = 1,2,...n \tag{5}$$

where ω_j is a non-normalized barycentric coordinate called a weight function for node *j* [18] yielding a polynomial as given in (6)

$$\omega_j = \frac{A(u_{j-1}, u_j, u_{j+1})}{A(u_{j-1}, u_j, p)A(u_j, u_{j+1}, p)} \text{ ; for } j = 1,2,..., n \quad (6)$$

so that when (6) is substituted into (5), the shape function becomes a ratio of polynomial A refers to a triangle area formed by three points as mentioned in the index with *P*(*x*,*y*) inside the element. Fig.3 shows an example of a polygonal element in a rectangular shape (*n*=5) with point *P*.

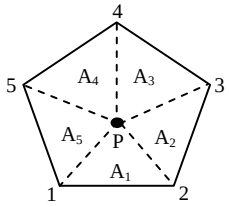

Figure 3. A pentagonal element as an example of polygonal elements.

An example calculation of a triangle area created by node *j*-1, *j* and *P*, $A(j-1, j, p)$ for $j = 2$, is formulated in (7) where it will give a positive number when the vertices are counterclockwise numbered.

$$A^e(1,2,p) = \frac{1}{2}\begin{vmatrix} x_1 & y_1 & 1 \\ x_2 & y_2 & 1 \\ x & y & 1 \end{vmatrix} \quad (7)$$

C. FEM Formulations

FEM formulation is built based on Galerkin method for both TM and TE modes based on the general formulation in (1). For TM mode case, the solution of the electric field E_z is approximated in the form of linear expansion of shape functions and unknown field parameter *u* as in (4). When the approximate field $\bar{u}$ is substituted in (1) for each kind of modes, a residual error *R*(*x*,*y*) will be obtained as in (8).

$$R = \frac{\partial^2 \bar{u}}{\partial x^2} + \frac{\partial^2 \bar{u}}{\partial y^2} + \left(\frac{\omega}{c}\right)^2 \varepsilon_r \bar{u} \quad (8)$$

According to the Galerkin's method, the integrals formed by integrating the product of residual error *R* and each shape function employed as a weighting function *w* are forced to zero as shown in (9) in order to minimize the error. By doing integration by part, a system of equations is obtained as given in (10)

$$\int_\Omega w_i R dxdy = 0; \text{ for } i = 1,2,...,n \quad (9)$$

$$\int w_i \frac{\partial \bar{u}}{\partial n} d\Gamma - \iint \left(\frac{\partial \bar{u}}{\partial x}\frac{\partial w}{\partial x} + \frac{\partial \bar{u}}{\partial y}\frac{\partial w}{\partial y} \right) dxdy + \iint w \left(\frac{\omega}{c}\right)^2 \varepsilon_r \bar{u} dxdy = 0; \text{ for } i = 1,2,..., n \quad (10)$$

Substituting (4) into (10) for unknown inside the element beyond the line integration and enforcing the PBCs in (2) and (3) for unknown on the element boundary will lead the formulation into eigensystem equation (12). The numerical integration is taken only inside the elements since nodes on element boundary will be imposed by the PBCs and the surface integration in (10) will be called as *f*(*x*,*y*). Numerical integration on polygonal element *e* is approached by means of partitioning it into *m* number of triangle e_Δ (sub-triangulation) and then using standard quadrature rules on triangles [18] where the element is the original physical element yielding an integration formulation as shown in (11)

$$\iint_e f(x,y)dxdy = \sum_{e_\Delta=1}^{m} \iint_{e,e_\Delta} f(x,y)dxdy = \sum_{e_\Delta=1}^{m} \int_0^1 \int_0^{1-\xi} f(\xi,\eta)\left|J_1^{e_\Delta}\right| d\xi d\eta \quad (11)$$

Finally, an eigensystem equation in matrix form as written in (12) can be obtained.

$$[A]\{u\} = \left(\frac{\omega}{c}\right)^2 [B]\{\phi\} \quad (12)$$

By solving (12) for a given wave vector *k*, the eigensolver computes a set of eigenvalues. These eigenvalues are plotted as a function of *k* yielding the band gap characteristic.

III. NUMERICAL RESULTS

The results from triangular FEM and polygonal FEM are validated by using results from plane wave expansion methods (PWE) as a semi analytical method by running MPB software with 128x128 resolutions. Fig.4 presents the results of band gap characteristic obtained by polygonal FEM for a square lattice PC of dielectric rods with ε_r=8.9 surrounded by an air medium for 5 numbers of bands using 4 gauss points.

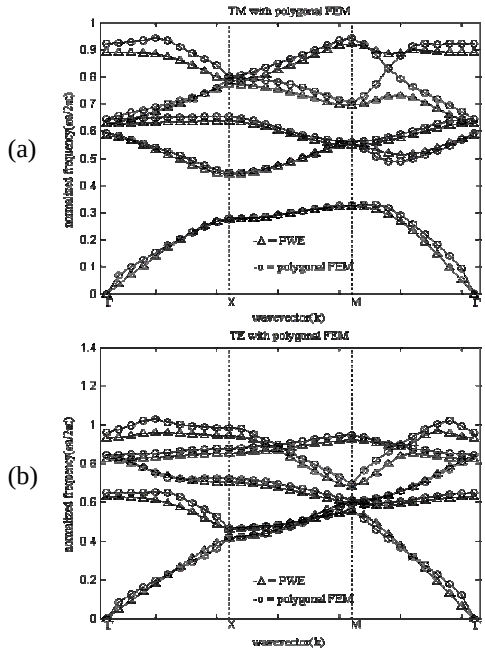

Figure 4. Band gap characteristic of a square lattice PC with ε_r=8.9 in a rod surrounded by an air medium for (a) TM and (b) TE mode.

The polygonal mesh is built by 116 number of nodes, 77 number of elements and 338 elements in sub-triangulation

while the triangular mesh is created from 186 number of nodes and 330 number of elements shown in Fig.2. The input wave vectors are sampled points from edges of the irreducible Brillouin zone (wave vector zone) by 10 cells for each edge plotted on horizontal axes. Certain parts of the bands look convergent with the comparative results especially for the lower bands and the error is around 3.713 %. It is convincible that this method can give greater accuracy with the proper design of the mesh.

Recent convergence test for 5 numbers of bands yields a graph shown in Fig. 5. The convergence rate test shows that the polygonal FEM with a polygonal mesh of all n>3 elements will give a quick step to converge than the linear triangular FEM until around 1000 numbers of unknowns.

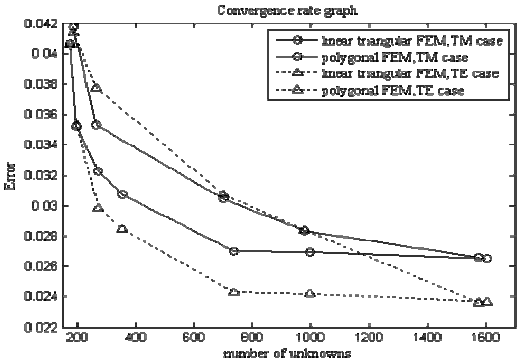

Figure 5. A comparative convergence rate graph between linear triangular FEM and polygonal FEM for both TE and TM mode cases.

Increasing unknowns until around 1600 numbers will bring the results into almost the same number of errors for both polygonal FEM and linear triangular FEM for each kind of modes with the same type of mesh where more refined elements are created in the rod rather than in the air medium. The more proper design of mesh is predicted to give better results.

Fig.6 shows a modification of polygonal mesh in Fig.2 which is combined with the linear triangular elements inside the rod called a mixed type mesh (right side of Fig.6) which indicates to give a better result i.e. 3.63 % where the number of triangle elements at least equal to the number of sub-triangulation created in polygonal mesh. It is shown that for un-fluctuating behavior of the system such as inside the rod where the field becomes more dominant rather than in the air medium, the use of linear triangular elements is enough while for the fluctuating one needs to use higher order elements such polygonal elements.

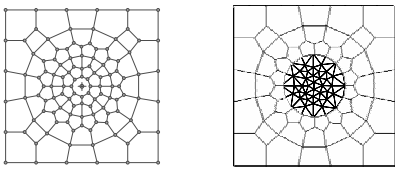

Figure 6. Comparison of a polygonal (left) and a mixed type mesh (right).

IV. CONCLUSION

Dealing with polygonal FEM, some parameters must be considered first in order to reduce the error or to increase the accuracy such as the numbers of used gauss points, external input values on boundary conditions, numbers of sub-triangulation elements depending on the problem. In this case, the polygonal FEM proves to give a higher accuracy than the linear triangular FEM where the lower error level is obtained by occupying less number of nodes (unknowns) and less number of elements.

***Abstract* —This paper first presents a tri-band microstrip (MS)-to-coplanar stripline (CPS) transition. Rather using a wideband transition for tri-band circuit integration, a triple band transition is proposed as the noise power of each band can be limited. The proposed transition is simple to implement thus suits for various applications. A MS-to-CPS transition design for operating at three simultaneous bands on a low-cost substrate has been performed. Simulated and experimental results are in good agreement. The proposed transition exhibits excellence insertion loss performance at three bands, which are 0.36, 0.78, and 0.82 dB, respectively.**

Index terms: Microstrip, coplanar stripline, transition, transmission line.

I. INTRODUCTION

Coplanar stripline (CPS) has a balanced structure [1] which ideally supports signal propagation with low common mode noise. Also, as being a uniplanar transmission line, low discontinuity parasitic and ease of mounting lumped component in CPS circuit are its main advantages. Therefore it has gained much attention for high-speed and wireless integrated circuit designs nowadays. In addition, balanced structure in CPS simplifies the issue of integration with some balanced subsystems, such as dipole antenna [2], baseband CMOS IC [3], singly or doubly balanced mixer [4], etc. There are several circuit and system designs based on CPS transmission line which show impressive performances, for example a wideband mixer [5], a high-Q resonator and low insertion loss filter [6], a wideband transition [7], a rectenna system [8], etc.

In developing and design process of CPS transmission circuit, a transition is usually to interface a CPS transmission line to another transmission line circuit [7],[9]. In addition, measurement the CPS circuit does need a transition to interface with measurement systems. Among the CPS transitions, microstrip (MS)-to-CPS transition is widely used as the microstrip transmission line is one of the most commonly found circuits [10]-[11]. In the past, there are a few MS-to-CPS transition proposed [7],[9],[12]-[13]. Most of the transitions are designed for wideband application to serve not only for circuit design but also for measurement system interfacing. However the wideband performance is sometimes not suitable for some certain applications. For example, applying a wideband transition to integrate with multi-band system may need extra filter for band separation to limit noise power in each band. It is quite obvious that a multi-band transition serves better for the circuit/system integration than a wideband transition.

The paper is organized as follows: Section II presents the design configuration of the MS-to–CPS transition. The circuit consists of coupled MS lines and dual-section open stub. The three cross-section view of the electric field distributions of microstrip line, coupled microstrip line, and CPS will be described. The MS-to-CPS transition operated for three simultaneous bands will be designed. Simulation and measurement of a tri-band MS-to-CPS transition will be presented in Section III. Comparison of measured and simulated transition performances will be also discussed and followed with the conclusion in Section IV.

II. A TRI-BAND MICROSTRIP-TO-COPLANAR STRIPLINE TRANSITION

Fig.1 shows a configuration of the proposed tri-band MS-to-CPS. The structure is composed of a dual-section microstrip line coupled with a dual-section open circuit transmission line. From Fig. 1, the dual-section transmission line has line width of W_1 and W_2 associating with length of l_1 and l_2, respectively. The dual-section open circuit transmission line has line width of W_3 and W_4 associating with length of l_3 and l_4, respectively. The input of the transition is a 50 Ω feed line of width W_F and length L_F. Note that a function of a 50 Ω feed line is only for signal launching, not regarding to transition function. The output of MS-to-CPS transition is a CPS of width W and gap G. Triple band operation in transition is succeeded with multi-band matching operation in dual-section MS line and open circuit MS line. The cross-section views of electric field (E-field) distribution for different reference planes are shown in Fig. 2. Fig. 2 (a) shows the MS line (plane A-A'). The E-field distribution from strip plane passes substrate to ground plane. Fig. 2 (b) shows E-field

distribution in coupled MS line section (plane B-B'). The E-field distributes from MS coupled to MS and passes substrate toward ground plane. For E-field in CPS line (C-C') shown in Fig. 2(c), since the configuration in the area has no ground plane but have two strips over the substrate, then the E-field distributes across only these two strips.

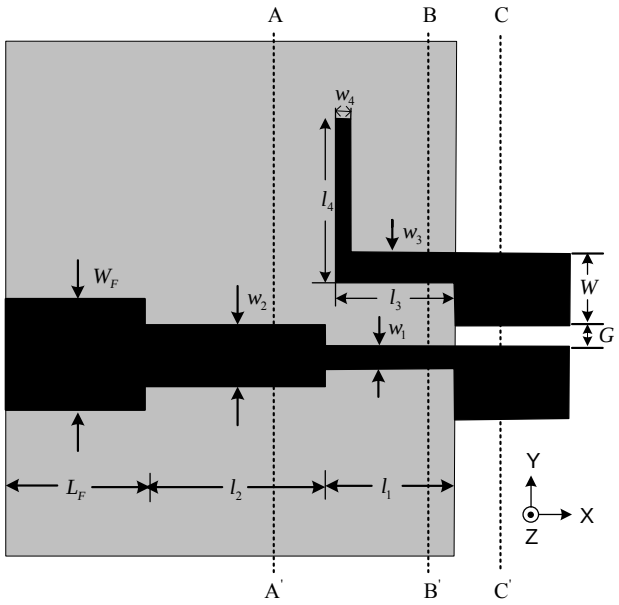

Figure 1. Configuration of the MS-to-CPS transition.

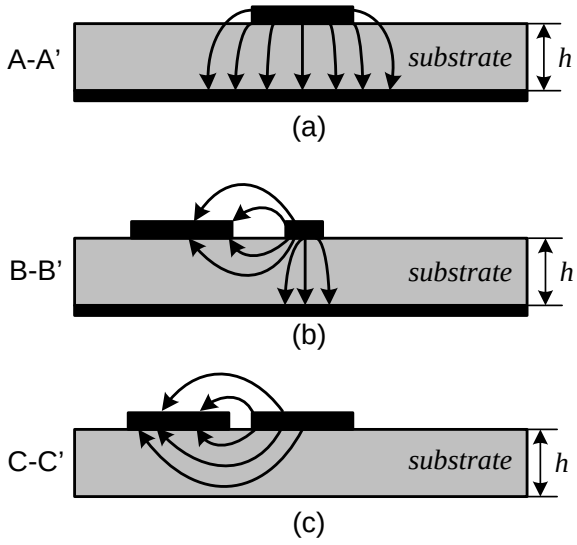

Figure 2. Cross-section view of the electric distributions: (a) microstrip line, (b) coupled microstrip line, and (c) CPS.

III. Results and Discussion

The proposed tri-band MS-CPS transition is designed for operating at 1800/1900 GSM band, WiMAX, and Wireless LAN. The bandwidth of each band was designed for supporting information bandwidth for each band application. In this paper, a low cost FR4 substrate is used to prove the concept. The parameters of substrate are as follows:- dielectric constant (ε_r) of 4.55 at 10MHz, thickness (h) of 1.6 mm, loss tangent of 0.02, and the conductor thickness (t) of 18 um. In the design stage, we assume that substrate is nondispersive media; that is its dielectric constant is independent with frequency.

In the initial design stage, the lengths of all transmission line sections were chosen at quarter-wavelength at the geometric mean frequency of upper- and lower-band center frequencies, i.e. 3.3 GHz. The width of each transmission line was initially selected at 115 ohm, which is equal to the differential impedance of the CPS line. With these initial design parameters, the circuit was simulated on Advanced Design System™ (ADS) platform and optimizer process was performed to reach the triple band operated. In our simulation setup, the number of cells per wavelength used in is equal to 25 at 7 GHz. This is the number compromising between speed and accuracy. The final design parameters associating with the circuit shown Fig.1 are listed in Table I. The lengths of 50 ohm line feeds at input and output ports are equal to quarter wavelength at 3.3 GHz. It should be noted that the digit number in millimeter dimension is one due to some limitations in our in-house fabrication process.

The MS-to-CPS transition with dimensions listed in Table I connected in back-to-back style was fabricated. Two SMA connectors from RADIAL were used for launching signal. Measurement was performed with an HP8710A network analyzer. The LRRM calibration method with a 3.5 mm calibration standard kit was done from 1 to 7 GHz. The measured data was collected via a GPIB port. The line feeds and connectors were de-embedded on ADS™ software.

Figure 3. PCB photograph of the triple-band microstrip-to-coplanar stripline

The print circuit board (PCB) photograph of the experimental MS-CPS connected in back-back style fabricated on FR4 is shown in Fig. 3 (a) and (b). The circuit size is around 8.5×3 cm^2. Fig. 4 (a) and (b) show the measured and simulated results of the return loss of the transitions connected in back-to-back style. The designed transition operates at three simultaneous frequencies of 1.8, 3.5 and 6.5 GHz. The measured result at the third band somewhat differs from the electromagnetic (EM) simulated result. Apart from the result in the third band, the measured return loss performances of the transition are agreed very well with the EM simulated results. The distinct difference occurs at high frequency region is expected to produced mainly from dispersive in FR4 substrate.

It is well known that ε_r of the FR4 substrate decreases with an increase in frequency. The impact of ε_r decreasing in FR4 substrate to the return loss behavior at, especially, high frequency region is taken into account. Fig. 5 shows the return loss responses of the transition from 5 to 7 GHz for three different ε_r values. It is shown that the matching frequency is shifted to higher frequency when ε_r is smaller. The simulated results obtained in Fig. 5 supports that a frequency shift of matching at high-frequency band is possible came from a dispersive nature in FR4 substrate [14]. Another possible cause is the tolerance from our in-house fabrication process.

The comparison of EM simulated and measured insertion losses of the proposed transition are shown in Fig 6. Note that the effect of line feed and connector were excluded. The measured loss performance agrees with the simulated one very well. From measured results, the insertion losses at three desired bands are around 0.36, 0.78, and 0.82 dB.

IV. Conclusion

A simple triple-band microstrip-to-coplanar stripline for modern communication application has been presented. The circuit rather simple as it composes of a dual-section transmission line and a dual-section open stub. The proposed triple band transition was demonstrated with the design operated for GSM, WiMAX, and Wireless LAN applications. The experimental results confirm the technique proposed. The frequency shifting at high-frequency band is expected to come from dispersive nature of the substrate used combination with the limitation in fabrication process. In fact this can be simply corrected without any difficulty.

***Abstract*-During the usage of a mobile phone, human head is the most exposed organ to electromagnetic wave, which is propagated from the radio frequency device. Due to electromagnetic induction, electrical current occur in a proper conductive medium, such as our biological organ. Hence, we have to investigate their effect on the human health. In this work, we have used the computerized modeling and simulation technique to study the strength of electrostatic field caused by an electrostatic source in a homogeneous material volume. First, we have constructed a voxel-based homogenous model of human head consisting of electric elements, i.e. the resistances. Then, we have implemented the simulation of voltage distribution caused by virtual voltage source. Under the application of the numerical technique in combination with electromagnetic theory, we have then simulated and visualized the distribution of electrostatic field strength over the volume. The results conformed to the expected theoretical behavior, so that we can use our results for further step.**

I. INTRODUCTION

To-date, the telecommunication inventions enhance our life style, but they can also cause harmful effects to human health [1][2][3]. Mobile phone as such a device propagates electromagnetic wave into its surrounding, in which human head as the next human organ during its usage is included. Studies of effect of electromagnetic waves on human body can be done by a direct or an indirect way. Real experiments on animals for example are the direct method. But these in vivo experiments on animals raise the question of ethic and also need the high technology process [4]. An example of the indirect method is the experiment with a realistic phantom model, which is for example filled with liquid that are equivalent to physical and electrical properties of human. Even though, this method does not involve with the question of ethic, but it raises the question of cost. Moreover, it is a complicated and inflexible method. Another example of indirect method is the modeling of human head based on the computer database system. This model was constructed to contain the physiological, anatomical, and physical characteristics of human organs [5][6][7].

In order to calculate the effect of electromagnetic propagation on human head, such as increment of temperature in tissue or specific absorption rate of energy, we need to know the distribution of the electric field strength over the involved domain [8]. First, we have constructed a voxel-based homogenous model of human head. After that, we have evaluated our model by simulating the distribution of voltage over the volume model, and comparing with the real measurement on our real resistor lattice [9][10][11]. In this work, we were going further. We have used the results of the calculated voltage distribution to simulate the electric field intensity distribution over our three-dimensional model of human head. The results were also visualized.

II. MATERIALS AND METHODS

A. *The Finite difference to construct a three-dimensional model of human head*

Finite difference method is the method for finding of approximation answer on a homogeneous material problem. This method separates the volume domain space into equidistant sub-domain, i.e. a cubic (Fig.1a). A sub-domain is also known as a voxel, hence the finite difference is also called as a voxel-based model.

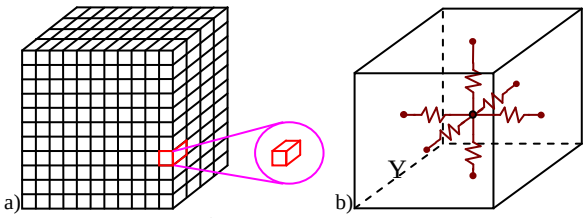

Figure 1. a) The separation of the volume domain into the small cubic, the so-called volume element (voxel). b) The structure of each voxel comprises of a reference node at the middle. Resistances modeling electrical properties spread out to the center of each rectangular side.

In order to model the electric properties of the sub-domain, each cubic has to be approached with an appropriate electrical element. Since the electrical current can be conducted in biological materials, the suitable electrical element of each voxel is resistance. Since, a cube has 6 joint sides, each voxel was assumed to contain 6 resistors, initiating at the center in the direction to each connection sides. The center point of each voxel is the referential node to the voltage of each single node (Fig.1b). Hence, several connected voxels result in a resistance lattice modeling human head (Fig. 2).

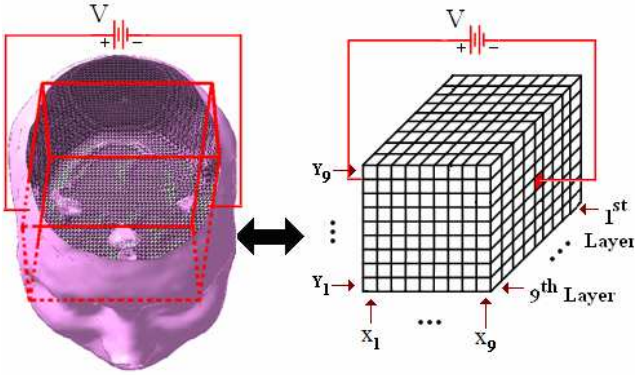

Figure 2. Human head was approached to a homogenous material of cubic form, and then modeled with the finite difference method, divided into 9x9x9 voxels. The injected voltage and grounding was then simulated at the showed position. (Note that each layer represents z coordinate) The voltage distribution was then simulated by the numerical calculation. (Fig from [12][13])

B. Electrical behavior of finite difference in 3D domain

Referring to the resistance structure within any voxel inside the volume model, any voxel *k* has six neighboring nodes i.e. *(k,1), (k,2), (k,3), (k,4), (k,5)* and *(k,6)* (Fig. 3). With the notation $V_{k,k}$ as the voltage value at the reference node k, $I_{k,i}$ the current flowing through between the reference node *k* and *i*, and the resistance value *R*, we finally formulized the sum of currents flowing through the node *k* in the three-dimensional circuit:

$$\sum_{i=1}^{6} I_{k,i} = \frac{3V_{k,k}}{R} - \sum_{i=1}^{6} \frac{V_{k,i}}{2R}, \qquad (1)$$

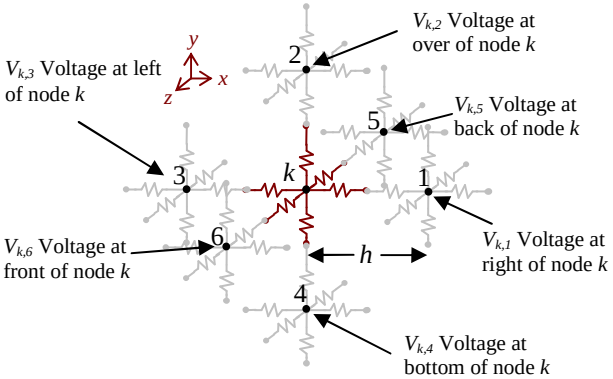

Figure 3. A voxel with its reference node *k* has normally 6 neighboring voxels. The distance between each node was denoted with *h*.

With the equation (1), the Kirchhoff's current law, and the fact that the sum of the inward and outward flowing currents at each node must be zero, we have concluded the linear equation:

$$0 = \frac{3V_{k,k}}{R} - \sum_{i=1}^{6} \frac{V_{k,i}}{2R}, \qquad (2)$$

with $k = 1, 2, 3, \ldots, (n_x \times n_y \times n_z)$,

where n_x, n_y, and n_z represents the number of element in *x*, *y*, and *z* axis.

To solve the linear equations system of three-dimensional domain, the equation can be written as matrix:

$$[I] = [A] \cdot [V], \qquad (3)$$

with [*I*]: the current vector of size $((n_x \times n_y \times n_z)+1)$,

[*A*]: the resistance matrix of size $((n_x \times n_y \times n_z)+1)^2$,

and [*V*]: the potential vector of size $((n_x \times n_y \times n_z)+1)$.

C. Numerical calculation of electrical field

In order to investigate electric field intensity, the gradient value of potential distribution was applied:

$$\vec{E} = -\vec{\nabla} V = -\left(\frac{\partial V}{\partial x}\hat{x} + \frac{\partial V}{\partial y}\hat{y} + \frac{\partial V}{\partial z}\hat{z}\right), \qquad (4)$$

with $\vec{E}$ represents the electric intensity field, and $\hat{x}, \hat{y}, \hat{z}$ unit vectors of *x*-, y- and z-axis.

For the numerical calculation of the gradient at any voxel, surrounded by neighboring voxels, we had to approximate the partial differentiation interval. For this purpose, we used the distance 2*h* between two neighboring reference nodes as the partial interval, so that the gradient value represents the center point of neighboring nodes:

$$\vec{\nabla} V_{k,k} \approx \frac{V_{k,1} - V_{k,3}}{2h}\hat{x} + \frac{V_{k,4} - V_{k,2}}{2h}\hat{y} + \frac{V_{k,5} - V_{k,6}}{2h}\hat{z}, \qquad (5)$$

with $V_{k,1}, V_{k,2}, V_{k,3}, V_{k,4}, V_{k,5}, V_{k,6}$ represents the voltages of neighboring nodes around node *k*.

Note that the estimation error of order $h^2, O(h^2)$ remains,

$$\vec{\nabla} V = \vec{\nabla} V_{k,k} + O(h^2), \qquad (6)$$

but we did not take it into account in this work.

For the boundary voxel, we applied the equation with the first forward divided difference, i.e. the distance between two adjacent nodes *h* as the partial interval, so that:

$$\frac{\partial V}{\partial x}\hat{x} = \frac{V_{k,1} - V_{k,k}}{h}\hat{x} \text{ or } \frac{\partial V}{\partial x}\hat{x} = \frac{V_{k,k} - V_{k,3}}{h}\hat{x}, \text{ for x-,}$$

$$\frac{\partial V}{\partial x}\hat{y} = \frac{V_{k,4} - V_{k,k}}{h}\hat{y} \text{ or } \frac{\partial V}{\partial x}\hat{x} = \frac{V_{k,k} - V_{k,2}}{h}\hat{x}, \text{ y-} \qquad (7)$$

$$\frac{\partial V}{\partial x}\hat{z} = \frac{V_{k,5} - V_{k,k}}{h}\hat{z} \text{ or } \frac{\partial V}{\partial x}\hat{z} = \frac{V_{k,k} - V_{k,6}}{h}\hat{z}, \text{ and z-axis.}$$

D. Numerical solving of linear equations system

Numerical solving of linear equations system can be done by several methods, e.g. the LU-decomposition method or the Gauss-Seidel method [14]. In this paper, we applied Gauss-Seidel method.

Since our matrix [*A*] has size of $((9x9x9)+1)^2$ or 532900 units, and if we focused on the characteristic of matrix [*A*], we found that a lot of positions has zero value (Fig. 4a). Only seven diagonals of the matrix show none zero value (Fig. 4b). Hence, in order to reduce the number of memory usage, we decided to collect the matrix elements lying on the principal diagonal as a single column matrix. As the next step, we have also defined other six single column matrixes to collect the other diagonal elements neighboring to the principal diagonal. Furthermore, we have defined another single column matrix to collect the information of voltage source position, which can be found in the first row of the matrix [*A*]. Finally, we have got a smaller matrix of size $[8((n_x \times n_y \times n_z)+1)]$ containing only

the diagonal elements of the matrix [*A*] and the voltage source position element (Fig. 4c). But since the information of the voltage position is a single value, we did not need to store other zero value for this special column, we have then got the new size of matrix [*A*] *NewS*:

$$NewS = 7((n_x \times n_y \times n_z)+1)+1, \quad (8)$$

so that, whereas the old size of matrix [*A*] = $((9x9x9)+1)^2$ = 532900 units. From equation (8), we have got the new size of matrix [*A*] = 7(730) + 1 = 5111 units.

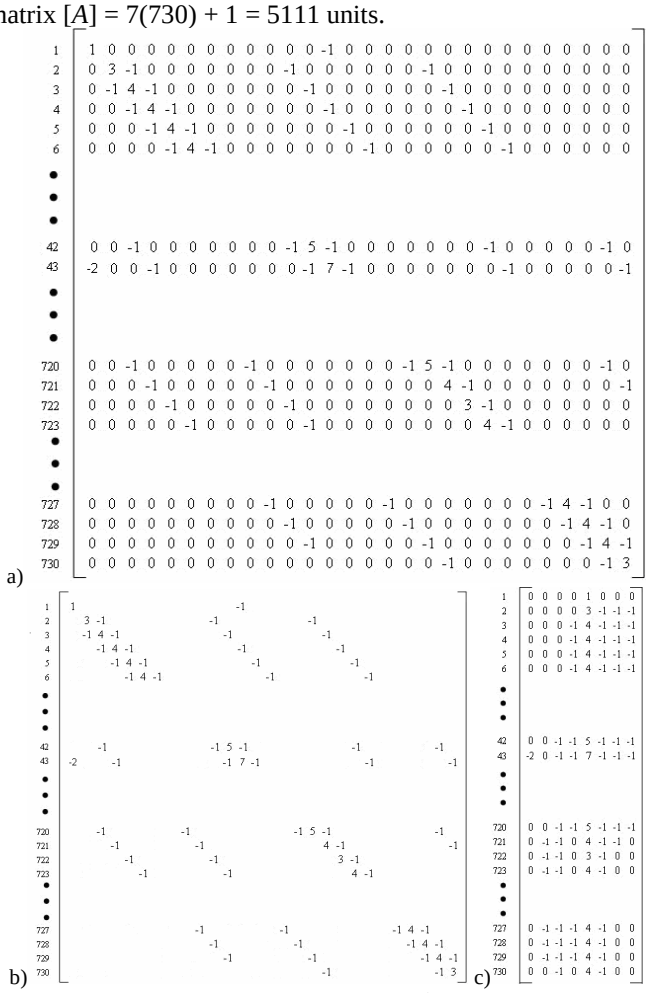

Figure 4. a) Since our volume model has the size of 9x9x9 units, the matrix [*A*] has the size of ((9x9x9)+1)2 = 532900 units, but containing about of zeros. b) Removing of zero elements show the value of matrix on seven diagonals. c) Collecting of specific values of diagonal elements together with the voltage source position value results into a new smaller matrix.

By collecting specific values of diagonal elements together with the voltage source position value into a new small matrix, the application of this *a priori* knowledge results in the total reduction of memory requirement over 99%.

III. RESULTS

A. *Simulation and visualization of potential distribution*

Assume that our model of human head is a cubic homogeneous volume domain. Then we separated it into connected small cubic sub-domains, by defining n_x = 9, n_y = 9, n_z = 9, whereas each voxel has six resistors and each resistor has a value of 5 *k*Ω. Each voxel has the dimension of 1 centimeter width. We then fed the electrostatic voltage source at point (1, 5, 5) and ground was connected at point (9, 5, 5) (Fig. 2). We then used the equations (1)-(2) to find the potential distribution over the whole volume model. The simulation results was satisfied both theoretical expectation and experimental verification (Fig. 5).

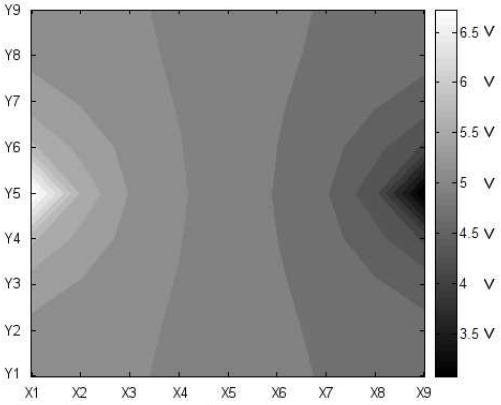

Figure 5. The equipotential line of potential distribution on 5th layer of z-axis. Color codes are shown in volt [V].

B. *Electrostatic field strength*

Finally, we have used the equations (3)-(7) under the application of the numerical method to find out the strength of electrostatic field caused by electrostatic voltage source on homogeneous material media, the depicted results are shown as table 1. We also have visualized the results, which were shown in figure 6 and 7.

Table 1. The values of the simulation of electrostatic field strength on the 5th layer (*xy* plane), which is the same layer of the voltage source, are shown a)b)c) by its vectorial components in *x*, *y*, and *z* direction, and d) its absolute value.

a) E_x on the 5th layer.

	x1	x2	x3	x4	x5	x6	x7	x8	x9
y9	3.0	3.9	5.4	6.1	6.3	6.1	5.5	4.1	3.1

y2	10.4	8.0	7.4	7.2	7.2	7.3	7.5	8.1	10.5
y1	5.8	5.3	5.8	6.2	6.4	6.3	5.9	5.4	5.9

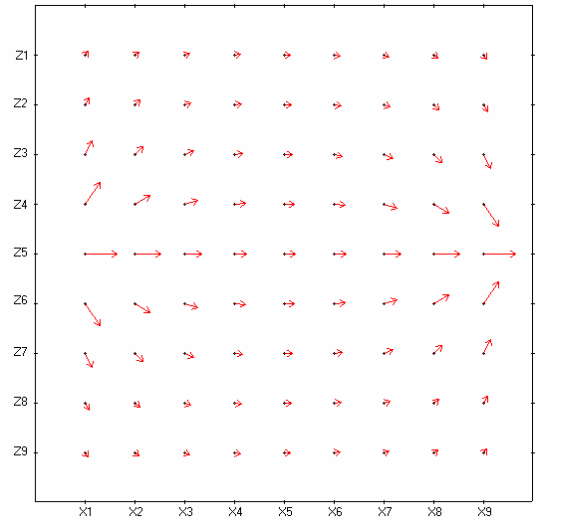

Figure 6. The arrows on the *zx* plane show both direction and size of electric field strength on the layer where $y = 4$.

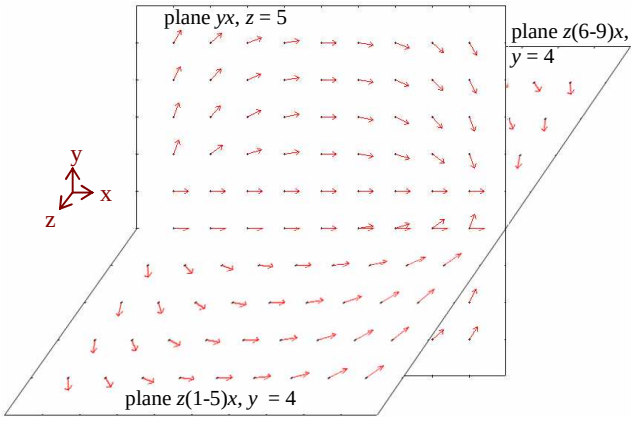

Figure 7. Cross view of two planes shows the direction of the simulated electric field distribution in the three dimensional domain. Cross line was at the level, where y = 4 and z = 5.

IV. Discussion

Even the fundamental theorem of this numerical implementation on a computerized voxel-based model was verified by the measurement of the voltage distribution on a real resistor lattice in an early study, further study will have to be launched in order to verify the current outcome. In order to study its effect on a closer-to-reality model of human domain, we shall use the voxel of size at least 1x1x1 mm^3. Furthermore, the integration of specific properties of human specimen e.g. density and conductivity will lead to the calculation of e.g. the specific absorption rate, so that the effect on human health can be quantified.

V. Conclusion

In this paper, we have simulated the electromagnetic propagation behavior of the electrostatic potential on a voxel-based biological domain model. By the mean of the computerized numerical method, we then calculated and visualized both the value and the direction of the electric field intensity distribution caused by electrostatic voltage source. The results fulfilled our expectation, hence can be used forwards further refinement and application.

***Abstract*- This paper presents a mathematical analysis of the system performance of three slot-based contention resolution algorithms for channel reservation namely *1/M, 1/n* and 1/(*M*-(*N*-*n*)) in terms of average number of successful users. The numerical results reveal that the system performance of the system depends on the number of users and the number of request slots per frame. Finally when comparing between all schemes it is found that the 1/*n* scheme is effective at systems with the number of slots greater than the number of users. However, when the number of users is large with respect to the number of slots per frame, the 1/(*M*-(*N*-*n*)) scheme offers relatively superior performance.**

I. INTRODUCTION

Medium access control (MAC) protocol is an essential part of a wireless access network which consists of a central base station and several wireless terminal users who communicate between them over a common wireless channel. Since in such a network users are usually geographically distributed over the service area and do not synchronize their transmission with each other, contention for uplink channel access becomes inevitable causing serious collision and usually resulting in low system throughput. Several MAC protocols have been developed to overcome this problem, for example ALOHA [1] and carrier-sense multiple access (CSMA) [2]. CSMA protocol and its variants such as CSMA/CD [3] and CSMA/CA [4] are widely used in most wired and wireless Local Area Networks.

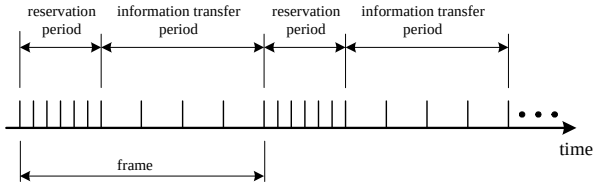

Figure 1. Frame structure.

In this paper we consider a specific class of MAC protocols as proposed in [5,6] which organizes the channel bandwidth into a frame structure that is composed of two alternate periods, namely reservation period and information transfer period, see an example of such a frame structure in Fig. 1. The reservation period consists of a fixed number of request slots, which are used by all users to reserve for channel bandwidth on a contention basis. A user who succeeds in the reservation process will be assigned the data slots by the base station in the information period for his information transmission. This class of MAC protocols has some interesting useful features, such as providing efficient bandwidth utilization, handling well with fluctuations in traffic demands, allowing Quality of Service guarantee, and offering fair channel access. One of the main problems in this protocol is how to resolve contention in reservation period in the most effective fashion. Reference [5] has addressed this problem comprehensively. Twelve contention resolution algorithms were introduced, mathematically analyzed and compared with existing classical protocols. Among these algorithms, the protocols called *Cascade Fixed Probability* (*CFP*) is considered one of the most appropriate for practical applications in high speed environment. However, the performance of the *CFP* has shown to be the least effective among all other schemes presented in reference [5], primarily due to its rigid contention resolution mechanism *i.e.* using a fixed value of access probability for all request slots. As a result, in this paper we attempt to improve the performance of the *CFP* by introducing a more flexible use of access probabilities; that is to use different values of probabilities for different slots as opposed to a single fixed value of access probability for all slots. It should be noted however that such a modification does not cause any fundamental changes to the *CFP*. In addition, the system performance can be improved as shown later in Section III. To achieve the desired performance improvement, one must be able to determine an appropriate set of probabilities. In this paper, we propose three different schemes namely 1/*M*, 1/*n* and 1/(*M*-(*N*-*n*)).

The paper is organized as follows. In the following section, we shall describe the details of *CFP* scheme. A complete system performance analysis of 1/*M*, 1/*n* and 1/(*M*-(*N*-*n*)) techniques is also mathematically derived in details. The numerical results and discussion are presented in Section III. Conclusions are given in Section IV.

II. REVIEW OF CFP SCHEME

In this section, we shall describe the detail of *CFP* scheme and its throughput performance derivation. The detailed description of the *CFP* algorithm and its throughput performance derivation can be found in [5] and [6]. However, the description of the *CFP* will be concisely presented again here to help understand the performance analysis.

In the *Cascade Fixed Prob* (*CFP*) scheme, each user will

attempt to make reservation on each request slot in sequence from the first slot to the last. In each slot, the user will decide whether it will access the present slot with certain probability of p and the value of this probability is the same for all users and fixed throughout all request slots.

Let $S_{CFP}[m,n]$ be the average number of successful users for the system with *m* users and *n* the number of request slots and $b[m,i,p]$ be the binomial probability that *i* out of *m* users access a particular request slot with permission probability *p*, which is expressed as:

$$b[m,i,p]=\binom{m}{i}p^i(1-p)^{m-i}\text{, where }\binom{m}{i}=\frac{m!}{i!(m-i)!}$$

In each request slot, only a single user can succeed in reservation, which will occur only when no other users access the slot. A more detailed analysis of $S_{CFP}[m,n]$ is formulated in a recursive form as follows:

$$\begin{aligned}S_{CFP}[m,n] &= b[m,0,p]S[m,n-1]\\ &+b[m,1,p](1+S[m-1,n-1])\\ &+\sum_{i=2}^{m}b[m,i,p]S[m-i,n-1]\\ &=b[m,1,p]+\sum_{i=0}^{m}b[m,i,p]S[m-i,n-1]\end{aligned}\quad(1)$$

where $m\ge 0, n\ge 0.$

The boundary conditions of (1) are $S_{CFP}[a,0]=S_{CFP}[0,b]=0$ where $a=0,1,2,.....,m-1,m$ and $b=0,1,2,.....,n-1,n$.

We can then find an appropriate permission probability $p_{CFP}[m,n]$ of each frame by differentiating (1) with respect to *p*, setting it to 0, *i.e.* $\frac{\partial}{\partial p}S_{CFP}[m,n]=0$ and determining *p* that gives the maximum average number of successful users $S_{CFP}[m,n]$.

III. Performance Analysis of Proposed Schemes

A. Description of 1/*M* scheme

In the *CFP* scheme, it is known that the system performance measured in terms of success probability depends on the value of *p* being used. Previous studies also show that an appropriate value of *p* exists and can be formulated as a function of the number of active users at the start of each frame (*M*) and the number of slots in each frame (*N*) as summarized in Section II. However, the computation time in determining the optimal $p_{CFP}[M,N]$ for each system configuration can be excessive, especially when the number of users and the number of slots are large. Therefore, it is felt useful to find a simple rule of thumb in determining appropriate value of *p* without having to perform excessive search for the optimum. For this reason, we propose a simple scheme in obtaining the effective value of *p* for the *CFP*. With this new scheme *p* is set to 1/*M* and hence this scheme is referred to as 1/*M*.

Let $S_{1/M}[m,n]$ be the average number of successful users for the system with *m* remaining users and *n* remaining request slots. $S_{1/M}[m,n]$ is computed as a recursive formula.

$$\begin{aligned}S_{1/M}[m,n] &= b[m,0,1/M]S_{1/M}[m,n-1]\\ &+b[m,1,1/M](1+S_{1/M}[m-1,n-1])\\ &+\sum_{i=2}^{m}b[m,i,1/M]S_{1/M}[m-i,n-1]\\ &=b[m,1,1/M]+\sum_{i=0}^{m}b[m,i,1/M]S_{1/M}[m-i,n-1]\end{aligned}\quad(2)$$

where $m\ge 0, n\ge 0.$

The boundary conditions of (2) are $S_{1/M}[a,0]=S_{1/M}[0,b]=0$ where $a=0,1,2,.....,m-1,m$ and $b=0,1,2,.....,n-1,n$.

B. Description of 1/*n* scheme

For the 1/*M* scheme, it is essentially the *CFP* scheme with *p* set to 1/*M*. Both CFP and its variant 1/*M* schemes apply a fixed value of access probability for all request slots. Study in [5] has shown that the early slots of *CFP* scheme usually support greater reservation demands than later slots, as the number of active users is generally higher at early slots than later slots. Therefore, using the same value of probability for early and later slots may not be effective in this situation. In the early slots, the value of probability should be small in order to avoid collisions. On the contrary, the users should attempt access the later slots at greater probability to reduce the number of idle slots and thus improving the overall system performance.

For these reasons, we propose the use of permission probability equal to 1/*n* (*n* = the number of remaining request slots in the system). In this scheme, the value of probability in the later slots is greater than the value of probability in the early slots. On average, it is expected that all request slots can be uniformly loaded and thus better utilized. The model for throughput analysis of this scheme is similar to that of the *CFP* scheme, though details may differ.

Let $S_{1/n}[m,n]$ be the average number of successful users for the system with *m* remaining users and *n* remaining request slots. In each request slot, only a single user can succeed in reservation, which will occur only when no other users access the slot. A more detailed analysis of $S_{1/n}[m,n]$ is formulated in a recursive form as follows:

$$\begin{aligned}S_{1/n}[m,n] &= b[m,0,1/n]S_{1/n}[m,n-1]\\ &+b[m,1,1/n](1+S_{1/n}[m-1,n-1])\\ &+\sum_{i=2}^{m}b[m,i,1/n]S_{1/n}[m-i,n-1]\\ &=b[m,1,1/n]+\sum_{i=0}^{m}b[m,i,p]S_{1/n}[m-i,n-1]\end{aligned}\quad(3)$$

where $m\ge 0, n\ge 0.$

The boundary conditions of (3) are $S_{1/n}[a,0]=S_{1/n}[0,b]=0$ where $a=0,1,2,.....,m-1,m$ and $b=0,1,2,.....,n-1,n$.

C. Description of $1/(M-(N-n))$ scheme

The problem of 1/*n* scheme is that it does not take the number of users into account. Accordingly, its performance can be significantly deteriorated when the number of users is relatively much higher than the number of slots available. This

is because all users will definitely place a reservation in one of the slots, collision will most likely be hard to avoid. To eliminate this problem, it is essential to find some means to limit the user attempts in accordance with the number of users and available slots. In this study, we propose a scheme which uses the permission probability for each slot equal to $1/(M-(N-n))$.

Let $S_{1/(M-(N-n))}[m,n]$ be the average number of successful users for the system with m remaining users and n remaining request slots. The average number of successful users of the $1/(M-(N-n))$ scheme can be expressed as follows:

$$\begin{aligned} S_{1/(M-(N-n))}[m,n] &= b[m,0,1/(M-(N-n))]S_{1/(M-(N-n))}[m,n-1] \\ &+b[m,1,1/(M-(N-n))](1+S_{1/(M-(N-n))}[m-1,n-1]) \\ &+\sum_{i=2}^{m} b[m,i,1/(M-(N-n))]S_{1/(M-(N-n))}[m-i,n-1] \qquad (4) \\ &= b[m,1,1/(M-(N-n))]+\sum_{i=0}^{m} b[m,i,1/(M-(N-n))]S_{1/(M-(N-n))}[m-i,n-1] \end{aligned}$$

where $m \geq 0, n \geq 0$.

The boundary conditions of (4) are $S_{1/(M-(N-n))}[a,0] = S_{1/(M-(N-n))}[0,b] = 0$ where $a = 0,1,2,....,m-1,m$ and $b = 0,1,2,....,n-1,n$.

IV. Numerical Results and Discussions

In this section, a numerical study is provided comparing the performance of the *CFP*, 1/*M*, 1/*n* and 1/(*M*-(*N*-*n*)) schemes. All results shown here are obtained from the mathematical formulations described in the previous sections. Computer simulations are also conducted to verify the accuracy of mathematical analysis.

Figures 2 and 3 illustrate the performance comparison of the *CFP*, 1/*M*, 1/*n* and 1/(*M*-(*N*-*n*)) schemes when the number of request slots equal to 8 and 32 respectively. The numerical result of *CFP* scheme is obtained by using appropriate permission probability $p_{CFP}[m,n]$. As we can see, the number of successful users of each scheme clearly increases with the number of slots in the area where the number of users is less than the number of slots available. However, when the number of users becomes greater than the number of slots, the *CFP*, 1/*M* and 1/(*M*-(*N*-*n*)) schemes still perform well whereas the number of successful users of the 1/*n* declines continuously. This is because 1/*n* scheme does not take the number of users into account. Therefore, its performance will clearly be degraded when the number of users is relatively much higher than the number of slots available whereas the *CFP*, 1/*M* and 1/(*M*-(*N*-*n*)) scheme can lower the risk of collision by reducing the permission probability and thus able to maintain efficient system performance. Note that the results of 1/(*M*-(*N*-*n*)) in the case of the number users more than the number of slots are not given here. This is because the probability of 1/(*M*-(*N*-*n*)) scheme will be negative in this situation.

Moreover, it is very interesting to see that the average number of successful users of 1/*M* is marginal less than the average number of successful users of *CFP* scheme. For this reason, if there are too many users and slots in the system the use of permission probability equal to 1/*M* helps reduce time to compute the appropriate permission probability $p_{CFP}[m,n]$ in the *CFP* scheme while maintains the throughput performance as high as the *CFP* scheme.

When comparing all the proposed schemes, it can be noticed that that 1/*n* scheme provide better performance than other schemes at systems with light to medium loads. In case of heavy load condition, the 1/(*M*-(*N*-*n*)) scheme offers relatively superior performance.

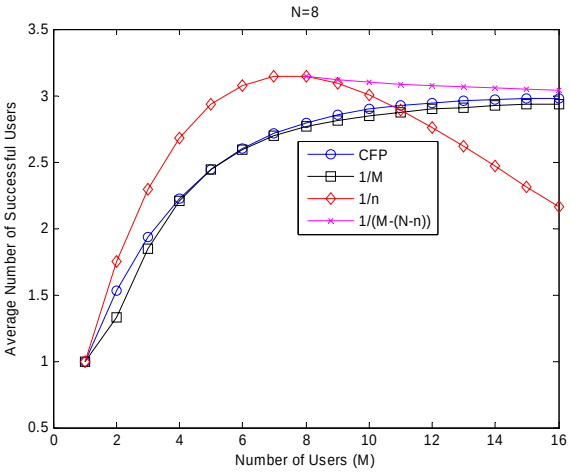

Figure 2. The average number of successful users vs the number of users (*M*) with the number of request slots (*N*) fixed at 8 for *CFP*, 1/*M* and 1/*n* and 1/(*M*-(*N*-*n*)) schemes.

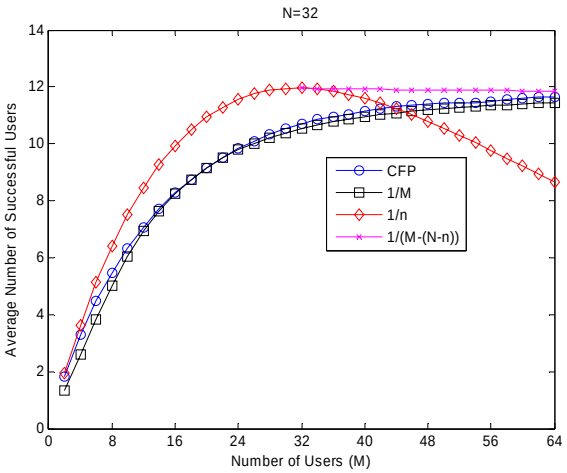

Figure 3. The average number of successful users vs the number of users (*M*) with the number of request slots (*N*) fixed at 32 for *CFP*, 1/*M* and 1/*n* and 1/(*M*-(*N*-*n*)) schemes.

ACKNOWLEDGMENT

V. CONCLUSION

In this paper, we have introduced three new channel reservation schemes for media access protocols in high bit-rate wireless systems. The mathematical analysis derived in this paper enables us to numerically evaluate the performance of all proposed schemes. It is found that the performance of *CFP* scheme can be improved by assigning different access probabilities to different request slots. At low to medium loads, i.e. the number of slots is larger than the number of users, the $1/n$ scheme can provide substantial gain in comparison to that of original CFP scheme where the access probability is fixed and of the same value for all slots. At heavy load conditions, i.e. the number of slots is smaller than the number of users, the $1/(M-(N-n))$ scheme offers superior performance to the *CFP* counterpart. Based on this study, we find that the appropriate set of probabilities for each slot can be expressed as $1/[\max(M,N)-(N-n)]$, which is a combined formulation of the 1/n and $1/(M-(N-n))$ schemes. In addition to this, we have suggested the $1/M$ scheme which is a simple but effective scheme in determining appropriate probability for the *CFP* with the same access probability for all slots.

***Abstract*-The modern wireless communication comforts human life, but mobile phones, for example, propagate the electromagnetic waves into environment, in which our head is also included. Therefore, we have to investigate their effect on the human health. For this purpose, a technique based on the application of computed simulation in combination with anatomic and physical model of human head was used. In this paper, we have simulated the two-dimensional distribution of SAR caused by isotropic antenna in inhomogeneous media, which consists of two layers of different specimens. We constructed a model containing an outer layer and an inner area which represents skull and brain respectively. Since the calculation of SAR depends on the electric field distribution, we assumed that the magnetic flux density would not depend on the varying of time. Our work focused on two frequencies, 900 MHz and 1800 MHz. The simulation was applied on a layered voxel-based cubic model. Electric field was fed by an isotropic antenna model which has the initial value of 20V/m. We found out that the maximal SAR in brain model was 0.1235 W/kg for 900 MHz and 0.1561 W/kg for 1800 MHz. Absorption effect of a low frequency radiation spreads over larger area than of that higher frequency.**

I. INTRODUCTION

To-date, the communication inventions enhance our life style, among them the wireless radio-frequency equipments are ubiquitous. Mobile phone as such a device propagates electromagnetic wave into its surrounding, in which human head as the next human organ during its usage is included. Although mobile phones provide convenient life, certain effects on human health remain unknown. Thus, we require methods to investigate their direct and indirect impact on the human health. Studies of effect of electromagnetic waves on human health can be done on several ways e.g. *in vivo* experiment on an animal [1][2], real measurement on a phantom model [3], or using computer-based numerical method with an application of a computer-based model [4]. Since the *in vivo* experiments on animals raise the question of ethic, real measurements on phantom models raise also a question of cost; numerical simulation with computer-based model remains an alternative method, which we have chosen to study the effect of electromagnetic wave on the human head. The so-called computer-based model of human head uses digital database comprising of the anatomic, physiologic, and physical characteristics of the human specimens. Application of various numerical methods can solve the problems of effect of electromagnetic wave on human health, since computerized numerical method provides a reasonable and flexible solution.

In order to quantify the effect of electromagnetic waves on human tissue, measurable quantity such as SAR (specific absorption rate) and temperature raise are to be investigated. Since the quantification measurement of temperature raise is extremely difficult to perform due to the very small temperature increments, which were reported to be less than 0.01°C [5], we have focused on the determination of SAR, which varies with the electric field intensity.

In this paper, we have studied electromagnetic theory of time varying field to simulate the electric field intensity on a planar domain of human head model. Then, we used the electric field intensity to calculate the specific absorption rate.

II. MATERIALS AND METHODS

A. The Finite Difference

Finite difference method is the method for finding of approximation answer on a homogeneous material problem. This method separates the domain of field space into equidistant sub-domain, i.e. a cubic (fig.1). A sub-domain is also known as a volume element (voxel), hence the finite difference is also called as a voxel-based model [6][7].

B. Construction of a Three-Dimensional Model

Application of a spherical structure, which comprises of different specimens on different layers, provides a simple layered head model (fig. 2a) [8]. The combination between the finite difference with the spherical layered model results in the multi-layers voxel-based model. In this paper, we have studied a two layers model consisting of an outer layer and an inner layer, which represents skull and brain respectively (fig. 2b).

C. Construction of a Two-Dimensional Model

Before we will apply the 3-dimensional model for our simulation, we have constructed a planar model to study the planar distribution of SAR. In the consideration of a cross section of figure 1 and 2b, we have got the square field domain. The outer boundary voxels represent skull. The voxels inside, we assumed them as brain (fig. 3).

D. Specific Absorption Rate (SAR)

The distribution of SAR in human head model was applied in this work to study effect of electromagnetic wave propagation through the human head. The application of this technique allows us to calculate the rate of energy absorption remaining in exposed human head specimen. This quantitative description has the unit of absorbed power per mass as W/kg or mW/g.

We can calculate the SAR for each specimen using the equation below [9]:

$$SAR = \frac{\sigma |E|^2}{2\rho}, \quad (1)$$

where E : Electric field intensity [V/m],
σ : Conductivity [S/m], and
ρ : Mass density of tissue [kg/m^3].

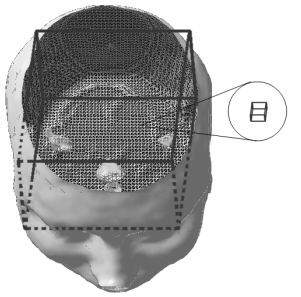

Figure 1 Separation of the volume space, which was used as the model of human head, into the small cubes, the so–called voxel (fig. from [7]).

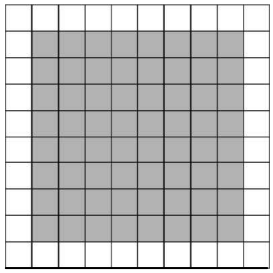

Figure 3 The planar field domain represents a voxel-based model of human head consisting of the boundary skull voxels (white) and the brain voxels (gray) therein.

E. Electric Field Intensity on a Plane

In order to calculate the SAR distribution on planar model, we have to know electric field intensity exposing to the planar domain [9]. In order to calculate SAR, we need to excerpt the electric field information out of the whole electromagnetic field. This allowed us to neglect the magnetic field, and hence also to assume that the magnetic field is not the time-varying field. We know that electric field caused by isotropic antenna as a point source propagating in any direction on plane. In general, the propagation of electric field can be expressed as [10]:

$$E = E_0 e^{-j\vec{k}\bullet\vec{r}} e^{j\omega t}, \quad (2)$$

where E : the distribution of electric field intensity,
E_0 : electric field intensity at ($\vec{r}$ = 0, t = 0),
$\vec{k}$: the propagation constant vector,
$\vec{r}$: the position vector,
t : time, and
ω : the radian frequency.

In our two-dimensional model of fig. 3, we can express $\vec{k}$ in terms of its x and y components:

$$\vec{k} \equiv k_x \hat{x} + k_y \hat{y} \quad , \quad (3)$$

where k_x and k_y represents k in x and y direction,
$\hat{x}$ and $\hat{y}$ are the unit vectors in x and y direction.

The position vector $\vec{r}$ can be similarly expressed as:

$$\vec{r} \equiv x\hat{x} + y\hat{y}, \quad (4)$$

so that $$E = E_0 e^{-jk(x+y)} e^{j\omega t}, \quad (5)$$

with $k_x = k_y = k$ in case of homogeneous media, and

x and y variable represents the distance from E_0 to E on x-axis and y-axis respectively.

The imaginary propagation constant can be expressed as explicit complex value [10]:

$$jk = \alpha + j\beta \quad \text{with } \alpha, \beta \in \Re, \quad (6)$$

where α : the attenuation coefficient, and
β : the phase constant.

Now we have got:

$$E = E_0 e^{-\alpha(x+y)} e^{-j\beta(x+y)} e^{j\omega t} \quad (7)$$

$$E = E_0 e^{-\alpha(x+y)} e^{j(\omega t + \beta(x+y))} \quad (8)$$

According to equation (1), SAR depends on the absolute value of E, so that:

$$|E| = E_0 e^{-\alpha(x+y)}. \quad (9)$$

The attenuation constant coefficient can be approximated in the dependency of frequency f [11]:

$$\alpha \approx \frac{\sigma(f)}{2}\sqrt{\frac{\mu(f)}{\varepsilon(f)}}, \quad (10)$$

where $\mu(f)$ is permeability of media, and
$\varepsilon(f)$ is permittivity of media.

F. Physical Parameters

One more important argument of a closer-to-reality human head model is the integrated physical parameter of human specimen. For all tissues, the relative magnetic permeability (μ_r) was set to 1 H/m [12]. The relative electric permittivity and the conductivity whose value depends on frequency are shown in table 1 [13]. In this work we have simulated two frequencies i.e. 900 MHz and 1800 MHz. In addition, the mass density of each tissue for calculating the SAR [13] is shown in table 2.

TABLE 1 VALUE OF THE RELATIVE PERMITTIVITY AND THE CONDUCTIVITY OF TISSUES MEASURED AT 900 MHZ AND 1800 MHZ (DATA FROM [13]).

Tissues	$\varepsilon_r(f)[F/m]$		$\sigma(f)[S/m]$	
	900MHz	1800MHz	900MHz	1800MHz
Skull	15.33	16.50	0.23	0.43
Brain	46.24	41.73	0.91	1.53

TABLE 2 THE MASS DENSITY OF EACH TISSUE (DATA FROM [13]).

Tissue	$\rho\left[kg/m^3\right]$
Skull	1772
Brain	1024

G. Discrete Technique of Electric Field Intensity in Each Element

In order to simulate the distribution of electric field intensity on the voxel-based planar domain of our head model, a technique was investigated to calculate under this condition. After separation of the exponential components of the equation (9) by the axial arguments, its calculation can be carried out on two steps:

$$|E| = E_0 e^{-\alpha x} e^{-\alpha y} \tag{11}$$

In order to calculate electric field intensity $E_{i,j}$ caused by any initial E_0 (fig. 4), we can first calculate $E_{i-1,j}$ which is also caused by E_0, on one hand. On the other hand, $E_{i,j}$ can be in analogue calculated also by using $E_{i,j-1}$. For a homogeneous media, both calculation sequences resulted in the same value of $E_{i,j}$.

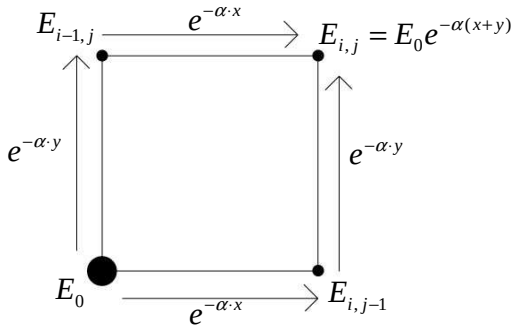

Figure 4 A point source (E_0) placed at the edge of a voxel. Arrows show the direction of calculation from point to point. $E_{i,j}$ is the electric field intensity caused by E_0 on the opposite position.

In case of inhomogeneous media however, electrical field has to cross continuous boundary, hence we used – as initial simplification – the approximated average value of both sequences to determine the value of the opposite position [12]:

$$E_{i,k} \approx \frac{E_{i,k|i-1,k} + E_{i,k|i,k-1}}{2} \tag{12}$$

where the index *i*, *k* represent x-axis position and y-axis position respectively,

$E_{ik|i-1,k}$ is the electric field intensity at position (*i*,*k*) caused by electric field intensity at position (*i-1*,*k*), and

$E_{ik|i,k-1}$ is the electric field intensity at position (*i*,*k*) caused by electric field intensity at position (*i*,*k-1*).

III. RESULTS

A. Electric Field Intensity Distribution

We have modeled an isotropic antenna, which propagates electric field intensity of 20V/m, and was placed at the center of the upper boundary of the planar model of 30x30 voxels by size (fig. 5). Each voxel is 5 mm width. The simulated results for the physical characteristics of specimen at 900 MHz and 1800 MHz were visualized and shown in figure 6, which shows that low frequency radiation has spread over larger area than higher frequency. Distribution of electric strength seems not to be different in term of both different frequency and different specimens.

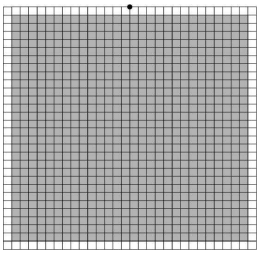

Figure 5 The two layers model consisting of skull and brain size of 30x30 voxels. The black point on the upper bound represents the position of the isotropic antenna.

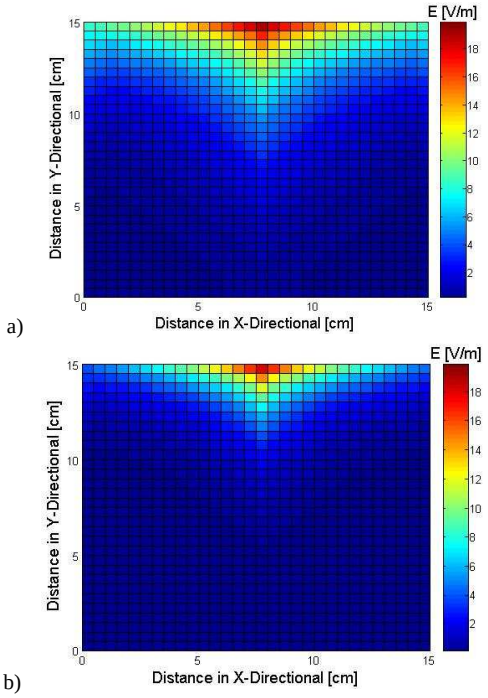

Figure 6 Visualization of electric field intensity distribution caused by a) 900 MHz and b) 1800 MHz isotropic antenna.

B. SAR Distribution

Finally, we calculated SAR distribution by using the equation (1). The visualization of SAR distribution caused by 900 MHz and 1800 MHz isotropic antenna was shown in figure 7. The maximum values of SAR in brain model are 0.1235 W/kg and 0.1561 W/kg in case of 900 MHz and 1800 MHz respectively. Moreover, both results show that there are very small values of SAR in skull layer; hence less amount of

energy was absorbed per mass unit in skull than in brain. Also here, we can see that lower frequency wave caused the larger area of absorption than the higher frequency field.

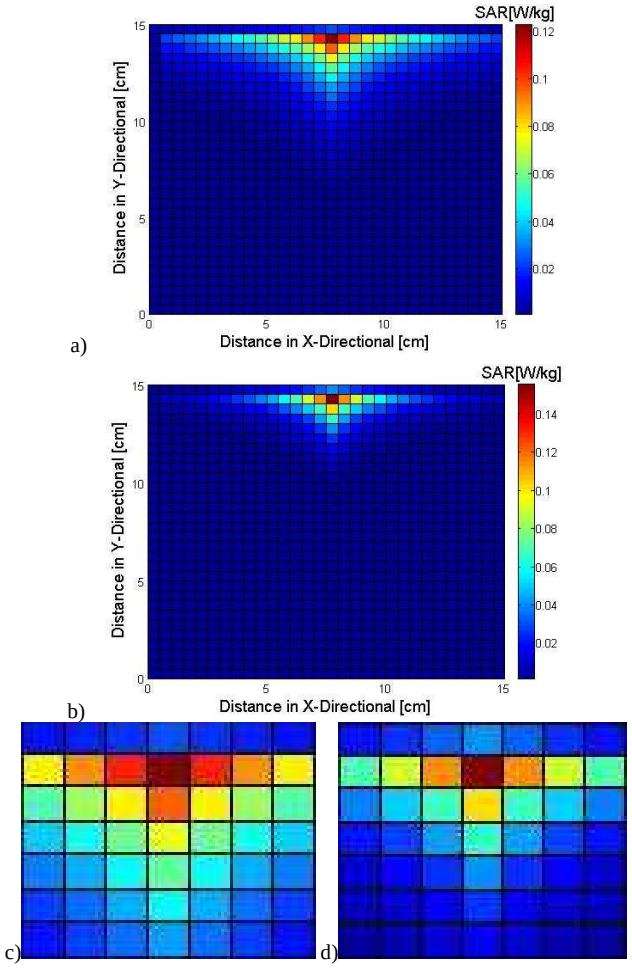

Figure 7 The visualization of SAR distribution caused by a) 900 and b) 1800 MHz isotropic antenna. c) and d) Magnifications of 7a) and 7b) respectively depicts the contrast of energy absorbed both in different specimens and different frequency causality.

IV. Summary

This work applied the finite difference method to construct the layered planar model of human head, consisting of skull and brain layers. Simulated electromagnetic wave propagation from isotropic antenna caused by higher frequency leads to a smaller absorption area, while lower frequency spreads over a larger absorption area. However, the largest value of SAR appears in the brain layer, which was exposed to higher frequency, thus in turn, SAR declines rather quickly than by lower frequency wave.

In consideration to the real biological domain, we concluded from our simulation results on the simplified model that first, the higher the frequency propagates from a device, the more involving specimen will absorb the energy. And second, that the quantity of the absorbed energy depends also on the specific mass density of each specimen, hence skull will absorbed less energy than brain.

V. Conclusions and Discussions

Our work was able to contrast the resulted SAR caused by two difference frequencies; but it is just a result of a simple model with the simple antenna. We still need to validate our results. The further step is the study of SAR distribution caused by the more complex antenna and the time varying field for approaching the realistic situation.

***Abstract*—The heart of the Wideband Code Division Multiple Access (WCDMA) Rake receiver lies in the design of the the channel estimator and equalizer. The application of Least Mean Square (LMS) and other adaptive filtering algorithms to WCDMA uplink receiver was proposed in 2002. In this paper, we propose the equalizer design based on the optimization of adaptive filtering techniques namely Normalize Least Mean Square (NLMS), Block Least Mean Square (BLMS) and Recursive Least Square (RLS). The BER performance of the Rake receiver is minimized with respect to various adjustable filter parameters. Our extensive simulation results show that the best performance is obtained when NLMS is used with well-tuned filter parameters. The optimal parameter selection process employed in this paper is based on the theoretical estimate along with the simulation search procedures.**

I. Introduction

One of the most promising approaches to 3G is the WCDMA air interface, referred as UMTS Terrestrial Radio Access (UTRA). A transmitted signal was simulated according to the physical layer specification of the IMT-2000 WCDMA system [8]-[9] i.e. the chip rate of the system is 3.84 Mcps, the frame length is 10 ms and each frame is divided into 15 slots (2560 chip/slot) and spreading factors range from 256 to 4 in the uplink. Then, the data is transmitted in a frame-by-frame basis through a time varying channel which is corrupted by the multipath fading environment. The signal is also further corrupted by additive white Gaussian noise (AWGN) at the front end of the receiver. In this paper, the focus of the study involves the design of the WCDMA Rake receiver with the emphasis on the uplink direction and the power consumption and processing cost are not of much concerned. The design, therefore, will be optimized to yield the highest processing performance measured in terms of BER.

This paper is organized as follows. First, the short overview of WCDMA communications is introduced. The theory behind the system is explained in section II. Then, the parameters in each type of filters are optimally selected according to their limitations and objections explained in section III. Lastly, in section IV, the performance of the filters are tested and discussed.

II. WCDMA uplink system

A. WCDMA Transmitter

At the transmitter, the signal will be sent as data sequence through DPDCH channel, whereas control information such as the transmit power control and pilot channel are sent through DPCCH channel. Each channel signal passes through different component, depending on its unique spreading factor and power ratio between DPDCH and DPCCH. For DPDCH, the data can be sent using different bit rates (depending on the application). Each case operates on different value of complex orthogonal spreading codes and bit-per-frame ratios. Furthermore, in DPCCH, four groups of bits are introduced, namely pilot channel, TFCI, FBI, and TPC, each of which has its own function. For pilot channel, it is used for defining the desired signal for channel estimation at the receiver. The control sequence is spread by complex spreading factor regardless of the data bit rates, then attenuated by the power ratio (β). DPCCH usually have lower power than DPDCH due to the fact that DPDCH contains more important data than DPCCH.

After spreading, the signals are complexly added. The combined signals are then scrambled using orthogonal codes which would prevent the interference from other users that uses the same frequency. The output of the transmitter, before being modulated, is a spread spectrum signal $s(t)$ described by following equation,

$$s(t) = [d_d(t)w_d(t) + j\beta d_c(t)w_c(t)] \cdot c(t).$$

Fig. 1 shows the overall system of transmitter.

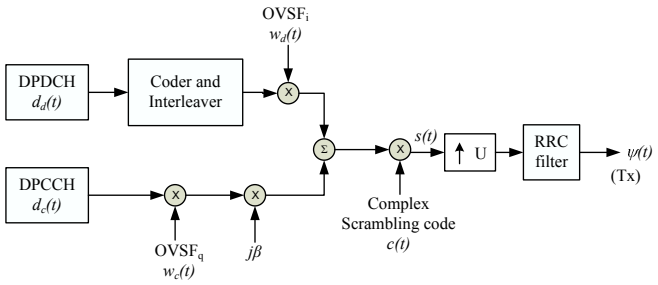

Fig. 1. WCDMA Transmitter

Throughout this paper, the simulation parameters are set according to Table I. We test the signal for 10 frames so altogether the signal contains 384,000 samples at four different bit rates varying from 12.2 kpbs to 384 kbps. The pilot channel is set according to 3GPP specification [10].

The input is usually up-sampled by the factor of 4, 8 or 16. In the experiment, we used the upsample factor of 4, thus, the chip rate after the upsampling becomes 15.36 Mcps. The pulse shape filter is put at the transmitter and the receiver for reducing the inter-symbol interference effect and the spectral bandwidth of baseband signals. Thus, we put the pulse shaping as a square root raised cosine type with the roll-off factor of 0.22 according

TABLE I

Transmitter parameter assignment

	I Channel				Q Channel
Bit Rate (kbps)	12.2	64	144	384	same as I channel
Bit per frame (bpf)	600	2400	4800	9600	150
Spreading Factor	64	16	8	4	256
N data (bit/slot)	10				0
N pilot (bit/slot)	0				6
Power Ratio P_Q/P_I (dB)	-5.46	-9.54	-11.48	-11.48	-

to the 3GPP specification. The amount of delay in the Rake receiver is adjusted by the path searcher (tracker).

B. Channel Model

The radio signal propagation through the air ("wireless channel") is influenced by many factors. Among them are reflections, diffraction, scattering and attenuation of the signal energy, caused by propagation loss and by natural obstacles such as buildings, mountains, etc. The well-known mathematical reference model due to Clarke [1] and its simplified simulation model due to Jakes [2] which have been widely used for Rayleigh fading channels. Multipath propagation is when signal from one transmitter takes different paths to get to the receiver. The receiver sees this as "echoes" with different arrival time and amplitude. With the usage of Rake receiver, these multipath signals are re-aligned and combined, by Maximum Ratio Combiner (MRC), to get a better signal-to-noise ratio (SNR) signal.

Assuming the maximum number of paths (or taps) to be L, the received signal at time t is

$$r(t) = s(t) \otimes h_b(t,\tau) + n(t),$$

where $n(t)$ is an additive white Gaussian noise (AWGN), $\otimes$ denotes the convolution operation, and $h_b(t,\tau)$ is the time-varying channel impulse response of a multipath channel and can be expressed as:

$$h_b(t,\tau) = \sum_{l=0}^{L-1} a_i(t,\tau)\exp[j(2\pi f_c \tau_i(t) + \phi_i(t,\tau))]\delta(\tau - \tau_i(t))$$

where $a_i(t,\tau)$ and $\tau_i(t)$ are the real amplitude and excess delay, *excess delay* is the relative delay of the l^{th}multipath component as compared to the first arriving component, the phase term $2\pi f_c \tau_i(t) + \phi_i(t,\tau)$ represents the phase shift due to free space propagation of the l^{th} multipath component, plus any additional phase shifts which are encounter in the channel,f_c is the carrier frequency and $\delta(\cdot)$ is the unit impulse response function.

In the simulation, we set the parameters, such as τ_i and a_i of channel impulse response $h_b(t,\tau)$ according to the 3GPP specification [10] shown in Table II. The adding phase shift $\phi_i(t,\tau)$ is randomly generated from $[-\pi,\pi]$, the carrier frequency for WCDMA is set at 2100MHz for the WCDMA [10].

For WCDMA uplink communications, the modulator is of QPSK type. However, we assumed that the modulator and demodulator are ideal and are ignored for simplicity. We followed the 6 cases of multipath Rayleigh fading channel according to the 3GPP specification 25.101 [3] as shown in Table II, for simulating the multipath Rayleigh fading channel.

TABLE II

3GPP specification 25.101

Case No.	Speed (km/hr)	Relative delay (ns)	Relative power (dB)
1	3	0 976	0 -10
2	3	0 976 20000	9 0 0
3	120	0 260 521 781	0 -3 -6 -9
4	3	0 976	0 0
5	50	0 976	0 0
6	250	0 260 521 781	0 -3 -6 -9

C. Base station Rake receiver

Upsampler block is compensated by downsampler block at the receiver side. The input to the receiver with chip rate of 15.36 Mcps is downsampled by factor of 4 (same as the upsampling factor) therefore, the chip rate after downsampling becomes 3.84 Mcps.

Rake receiver utilizes multiple correlators to separately detect strongest multipath components. Ideally, the Rake receiver should have L fingers, illustrated by Fig. 2 with $L = 3$. However, it is more practical to have M fingers ($M \leq L$) due to the complexity and hardware constraint.

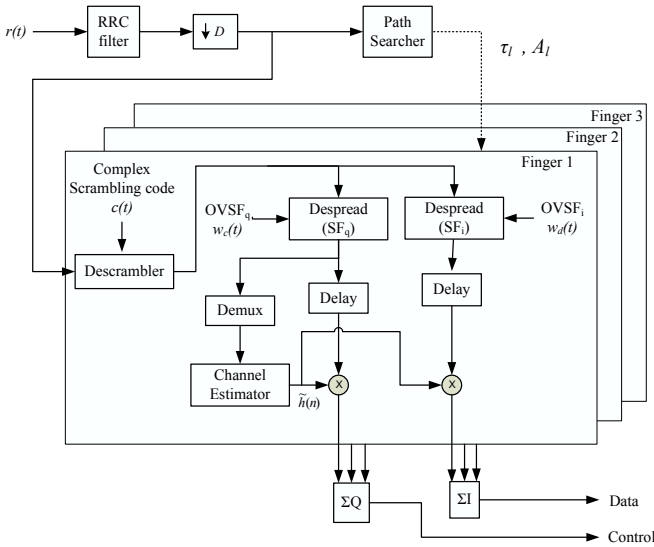

Fig. 2. Block diagram of Rake receiver

At the RAKE receiver, the first process is descrambling process and can be done by multiplying the input signal

with complex conjugate of the scrambling code. After descrambled at the receiver, the received l^{th}-path signal can be expressed as

$$\begin{aligned} r_l(t) &= [s(t)h_l(t) + n(t) + i(t)]c^*(t) \\ &= s(t)h_l(t)c^*(t) + n(t)c^*(t) + i(t)c^*(t) \\ &= [d_d(t)w_d(t) + j\beta d_c(t)w_c(t)]h_l(t) + n(t)c^*(t) + i(t)c^*(t) \end{aligned}$$

III. Channel equalizer by adaptive filter

Since the natural distortion and interference is usually predictable, it is necessary for the corrective system to identify and continuously adapt to the, often, time-varying condition. Such a system is called an adaptive equalizer [5]. In this paper, we compared three linear adaptive equalizers: NLMS, RLS and BLMS.

A. NLMS Algorithm

The normalized-LMS is similar to the standard LMS filter [5], but with the weight controller applying a weight adjustment. The NLMS algorithm sets an upper limit on scale factor (μ), resulting in more stable convergence and steady state coefficient values. The normalized μ is adjusted with the data as follow: (to avoid problem when $\|x(n)\|^2 \approx 0$, so, adding with an offset parameter (β))

$$\mu(n) = \frac{\alpha}{\|x(n)\|^2 + \beta}$$

where α is the scalar step size ($0 < \alpha < 2$), β is the offset parameter ($\beta > 0$) and $\|\cdot\|$ is the Euclidean norm.

The filter update algorithm is

$$w(n+1) = w(n) + \mu(n)e(n)x(n)$$

Fig. 3 and Fig. 4 demonstrates how the BER of NLMS

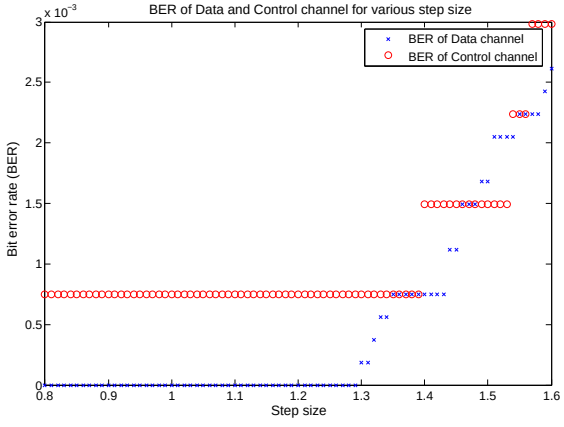

Fig. 3. BER performance at different step sizes values

algorithm behaves for various step size and offset value respectively. After many simulations, we found that an optimal step size mostly falls in the range of 0 to 1.29 (SNR = 0 dB). Later, we chose the step size $\alpha = 1$ for fast convergence speed and smaller BER. Clearly from Fig. 4, the larger offset (with step size α =1) results in the lower BER, since the offset ($\beta > 0$) is added to avoid the problem of $\|x(n)\|^2 \approx 0$. Here, we chose the optimal offset value = 50.

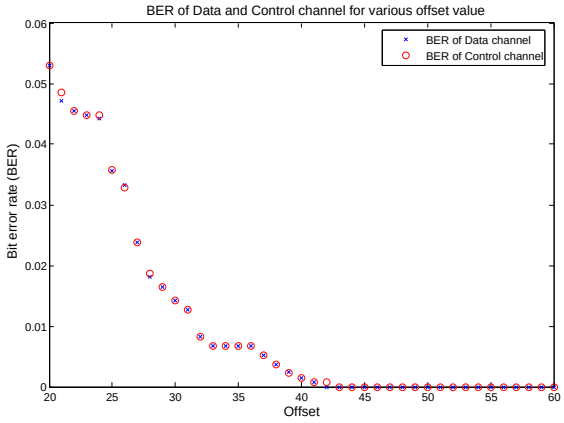

Fig. 4. BER performance at different step offset values

B. RLS Algorithm

The concept of Least Square method is based on the matrix inversion lemma. An important feature of this algorithm is that its rate of convergence is typically an order of magnitude faster than that of the simple LMS filter, due to the fact that RLS filter whitens the input data by using the inverse correlation matrix of the data. This improvement in performance, however, is achieved at the expense of computational complexity of the RLS filter [5].

There are at least three parameters the designer should carefully set. First is the forgetting factor, chosen in the interval $0 < \lambda < 1$. Since the signal is time-varying, the forgetting factor is usually optimal at the value between 0.95 and 1. Next, the filter length can be any designer's choice. From our experiment, using severely time-varying system, the more the filter length is, the higher the BER. Therefore, filter length of 1 is used. Lastly, the initial inverse autocorrelation matrix can be set by setting the value of regularization parameter. The optimal regularization parameter is tested and found to be just the identical matrix I alone.

We start by first obtaining the optimal forgetting factor. The relationship between forgetting factor (x axis) and BER (y axis) is shown in Fig 5. Note that Fig 5 is of bit rate=12.2 kbps and SNR=12dB. By testing the relationship between forgetting factor and BER at different bit rates and different SNR, we found that the optimal forgetting factor that makes the smallest BER is $\lambda = 1$.

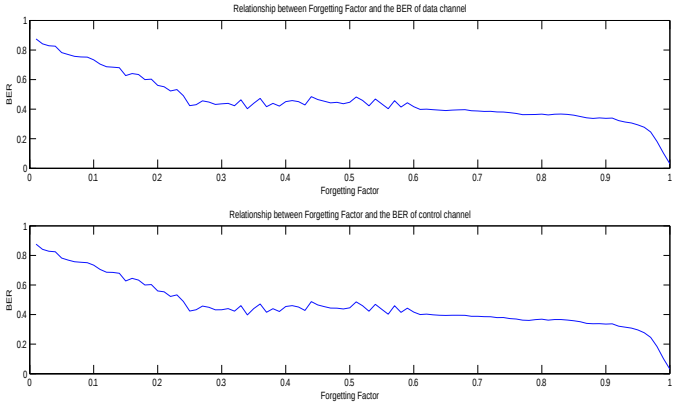

Fig. 5. Relationship between forgetting factor and BER

C. BLMS Algorithm

In Block LMS, the incoming data sequence $x(n)$ is sectioned into $L-sample$ blocks by means of serial-to-parallel converter, and the blocks of input data so produced are applied to an FIR filter of length M, one block at the time. The tap weights of the filter are updated after the collection of each block of data samples, so that adaptation of the filter proceeds on a block-by-block basis rather than on a sample-to-sample basis as in the conventional LMS algorithm. Block LMS algorithm is developed from the LMS algorithm, therefore it has several properties that are similar to those of the conventional LMS algorithm. However, one fundamental difference between them is the estimates of the gradient vector used in their respective implementations. Block LMS algorithm uses a more accurate estimate of the gradient vector, compared to the estimate of that of conventional LMS, because of the time-averaging, with the estimation accuracy increasing as the block size L is increased. Another disadvantage of BLMS is its slow adaptation behavior.

IV. Simulation and result

With the well-tuned of the parameters of adaptive filters, the simulation results measured in terms of BER using different adaptive algorithms at different bit rate and noise condition are reported.

For the NLMS algorithm; we found that the optimal step size of 1, offset = 50, leakage = 1 and filter tap of 32. The RLS algorithm; we found the best performance of BER when optimal forgetting factor of 1 and filter tap of 1. Note that the BER obtained by RLS algorithm has the lowest value of 0.000746 which is equivalent to 4 bits. These error bits occur during the initialization of the weight function $w(n)$ due to zero initial value for $w(n)$. Finally, the BLMS algorithm; we found the best performance of BER by setting step size = 0.01, leakage = 1, filter tap = 1, and block size = 2. The BER obtained by using BLMS algorithm has the lowest value of 0.001493 which is equivalent to 4 bits. These error bits occur during the initialization of the weight function $w(n)$ due to zero initial value for $w(n)$.we simulate the channel equalization using these 3 adaptive algorithms and the results are compared in Table III for data channel (I) and control channel (Q). Note that since moderate number of bits (over 10 frames) are simulated, the BER performance of the NLMS algorithm of zero might not be accurately represented, and only the trend can be used for conclusion.

V. Conclusion

In the WCDMA uplink transmission, the data and control signals are spread and scrambled before being modulates and propagates in the multipath environment. These multipath signals were received by the Rake receiver at the base stations. Here, we proposed to improve the performance of the Rake receiver by using channel estimator with various linear adaptive algorithms. The BER performance of several linear adaptive algorithms at various levels of SNR are compared. The optimal step size for NLMS is found to be $\alpha = 1$ and used throughout all later simulations. We discover that NLMS linear adaptive filter algorithm is the best algorithm in the specified environment as it has rapid convergence rate and the lowest miss-

Closed-Form Analysis of Equal Gain Combining for Wireless Communications Over Rayleigh Fading Channels

Narongrit Mekloi
Department of Electronic and Telecommunication Engineering, Faculty of Engineering
Rajamangala University of Technology Krungthep, Bangkok, 10120, Thailand

Abstract

Probability of outage is an important statistical measure in the design of cellular mobile radio systems which operate in a fading environment with multiple interferers. We derived the exact outage probability of dual branch equal gain combining (EGC) in wireless systems in presence of co-channel interference. The more general case with unequal power co-channel interferers is formulated and solved differently in this paper ending up with closed form solutions for Rayleigh fading channel models.

Keywords: Co-channel interference (CCI), Equal gain combining, Outage probability, Rayleigh fading

1. Introduction

Diversity technique is a well known method for mitigating the effects of multipath fading in wireless communication systems. Various techniques are used to combine the signals from multiple diversity branches. The most main of them are selection combining (SC), equal gain combining (EGC), maximal ratio combining (MRC) and hybrid diversity or called Generalized Selection Combining (GSC). The MRC need the knowledge of amplitude and phase of the signals to maximize the signal power. Therefore, the implementation needs some mechanism to measure these properties such as phase lock loop etc. For this reason, the EGC, which characterized as MRC with equal gain is employed in stead [1]. Equal gain combining is of a practical interest because it provides performance close to optimal maximal ratio combining but with greater simplicity [2].

Besides the probability of bit error, the outage probability is important measure of performance of mobile system operating in the presence of interferers over fading channels [3]. A system planner cans use outage probability calculations to assess the effects of various system configurations on the quality of service provided by the system. The outage probability is defined as the probability of failing to simultaneously achieve a signal-to-interference ratio (SIR) and a signal-to-noise ratio (SNR) sufficient to give satisfactory reception is an appropriate measure to evaluate the performance of a mobile radio systems. The outage probabilities based on either SNR or SIR have been reported [4]-[9].

Although previous studies on outage probability deal with a variety of channel models, the closed form of outage performance has not derived in literatures. Performance evaluation of EGC diversity systems is notoriously difficult only more so given that the closed form probability density function (pdf) of the EGC output is only available for dual diversity combining in Rayleigh fading. In this paper, we deal with the dual branch diversity EGC special case relevant to small-size/mobile communication units. Previous related work, performance evaluating of a broad class of modulation schemes employing EGC receivers in a variety of fading environment was analyzed in [10], where only the signal to noise ratio (SNR) was considered. However, an interference-limited fading environment as in cellular communication systems where the level of the co-channel interference is sufficiently high as compared to the thermal noise. The analysis in [11] was derived the SIR of EGC in co-channel interference, were only the ratio of mean signal power to mean interference power was considered in the case of equal interferer powers. In many operational environments, however, the interferer powers may be different.

In the following, we present a closed form of outage probability analysis of dual diversity using EGC in Rayleigh fading with CCI. Section 2, shows the system model for interference power calculation. The performance analysis is then derived in the Section 3. In Section 4, present numerical outage calculations for varying numbers of interferers for unequal power and the conclusion is provided in Section 5.

2. Signal and Receiver Model

Consider a communication systems in which the receiver with a dual diversity receiver operates in the presence of L independent co-channel interferers. Throughout this paper, it is assumed that the system performance is interference limited and that the effect of thermal noise is negligible. The 2 × 1 complex baseband received signal for dual-antenna diversity reception is given by

$$r(t) = s_0(t)\mathbf{A}_0 + \sum_{i=1}^{L} s_i(t)\mathbf{A}_i \qquad (1)$$

where L is the number of interfering signals, $s_i(t)$ (i=0,1,2,3,…,L) are the transmitting signals and $\mathbf{A}_i$ (i=0,1,2,3,…,L) are the M-dimensional direction of arrivals of desired signal (i=0) and ith interfering signals, respectively. We thus have the instantaneous SIR at the output of equal gain combiner, assuming interference power calculation over diversity branches is

$$\gamma = \Lambda_i \frac{\left|\sum_{j=1}^{M} \alpha_{s,j}\right|^2}{\sum_{j=1}^{L} \left|\beta_{i,j}\right|^2} \quad (3)$$

where $\Lambda_i \equiv P_s / P_i$, for $i = 1, 2, ..., L.$ is the power ratio of desired signal to the *i*th interfering signal, and $\alpha_{s,j}$ and $\beta_{i,j}$ are fading amplitudes of desired and interference signals and are zero-mean Gaussian distributed, respectively. The fading amplitudes $\alpha_{s,j}$ and $\beta_{i,j}$ are Rayleigh distributed as

$$f_\alpha(\alpha) = 2\alpha e^{-\alpha^2}, \qquad \alpha \geq 0. \quad (4)$$

3. Outage Probability

The outage probability is the probability of failing to achieve adequate reception of a wanted signal, is a useful statistical parameter for assessing the quality of radio reception in mobile communication systems. In EGC, the desired signals at the outputs of the antennas are co-phased, equally weighted and then summed to give the resultant desired signal. The exact outage probability can be derived for *M* = 2. The cdf of sum of two i.i.d. Rayleigh RVs is known [12], and the conditional outage probability for *M* = 2 is

$$\Pr(X < \sqrt{\gamma\omega}) = 1 - e^{-\gamma\omega} - \sqrt{\frac{\pi}{2}\gamma\omega} \times e^{-(1/2)\gamma\omega}\left[1 - erfc\left(\sqrt{\gamma\omega/2}\right)\right] \quad (5)$$

Letting $X = \sum_{j=1}^{M} \alpha_{s,j}$ and $\omega = \sum_{i=1}^{L} \left|\sum_{j=1}^{M} \beta_{i,j}\right|^2 / \Lambda_i$ when the interferers have unequal mean powers the pdf of α is given by [13, eq. (14.5-26)]

$$p_\alpha(\alpha) = \sum_{k=1}^{L} \frac{\Lambda_k}{M} \pi_k e^{-(\Lambda_k / M)\alpha}, \qquad u \geq 0 \quad (6)$$

where

$$\pi_k = \prod_{\substack{i=1 \\ i \neq k}}^{L} \frac{\Lambda_i}{\Lambda_i - \Lambda_k} \quad (7)$$

Averaging (5) with respect to (6) for $p_\alpha(\omega)$ gives the outage probability. In case of unequal interferer powers, using [14, eq.3.478, 6.286], is shown in the equation (8) at the bottom of the next page. The mathematical function ${}_2F_1(a,b,c;z)$ in (8) is the hypergeometric function [14].

4. Numerical Examples

In this section, we present some numerical results by plotting the outage probability SIR γ when the channel undergoes Rayleigh fading. To study outage for unequal interferer power distributions, define

$$\Lambda_{avg}(\text{dB}) = 10\log_{10}\frac{P_s}{\frac{1}{L}\sum_{i=1}^{L} P_i}$$

we define vector $q = [q_1, q_2, ..., q_L]$ of normalized interference power, where $\sum_{i=1}^{L} q_i = 1$. Power ratio

$$\Lambda_i(\text{dB}) = \frac{P_s}{P_i}(\text{dB}) = \Lambda_{avg}(\text{dB}) - 10\log(Lq_i).$$

Figure.1 plots the outage probability for the number of antennas (*M*) = 2 with number of interferences as a parameter for the case of non-identical interferer powers. Example for the interference power vector for L=6 is [0.05, 0.1, 0.15, 0.22, 0.23, 0.25]. As expect the system performance increases significantly as the number of interferences decreases. In Figure.2, we compare a Monte Carlo simulation of the outage probability using (3) with the analytical outage probability using the interference power calculation method for the case of unequal interferer powers. As shown, the analysis and simulation results agree closely.

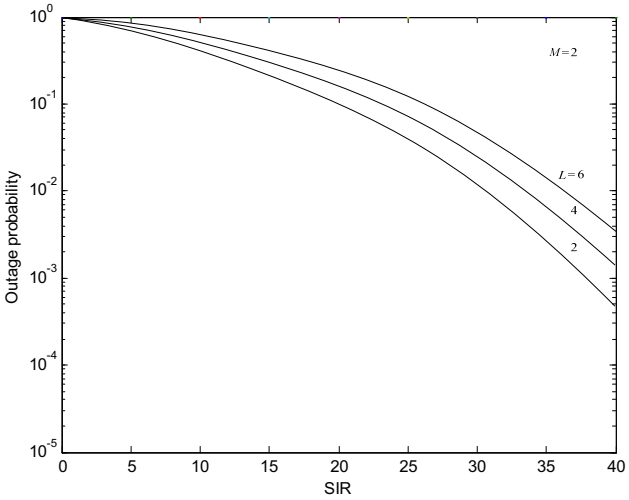

Fig. 1 Outage probability for non-identical ($\Lambda_{avg} = 10$ dB) interference power with *M* = 2 and *L* = 2, 4, and 6 interferences.

5. Conclusions

In regard to the EGC receiver performance analysis in Rayleigh fading channel, the framework in this paper has been presented in closed-from expressions for

outage probability for dual diversity systems. We have studied the effect of co-channel interference on the performance of digital cellular mobile radio systems. The new analysis method assumes that the interferers add in amplitude and phase, were the interfering signal components are across antenna array elements. The analysis assumed an arbitrary number of co-channel interferers with different average powers.

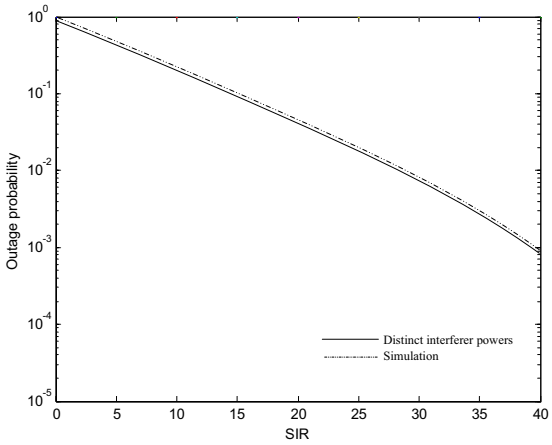

Fig. 2 Analytical outage probability for non-identical power calculation and Monte Carlo simulated outage probability for unequal interference power distributions with $L = 2$ interferers and $M = 2$ antennas. The interference power vector for $L = 2$ is [0.1, 0.9].

***Abstract*-Spam is considered a significant security problem for computer users everywhere. Spammers exploit a variety of tricks to conceal parts of messages that can be used to identify spam. This paper presents an email feature extraction technique based on artificial immune systems. The method extracts a relatively small set of features that can be used as inputs for a classification model. A Backpropagation neural network is employed as the spam detection model. The performance evaluation against a standard spam collection and reference systems shows that the proposed approach performs well compared to other systems with large sets of features, rules, or external evidences. The detection rate of the best system in this study is 92.4%, with 1% and 13.8% of false positive and false negative rates, respectively.**

I. INTRODUCTION

Spam, unsolicited, undesired, bulk email (or junk email), has been a significant security issue for computer users and a massive waste of time, disk spaces, and network bandwidths. As spam filters evolve better in abilities to identify and discard spam, spammers develop new tricks to circumvent the filters.

The most common method is to hide the parts of a message that make it spam, such as splitting words, dynamically generating messages by JavaScript, using images of words, encoding characters, ASCII art, etc. These methods are effective especially with HTML which provides a rich set of tools for creating messages. They can send rich messages with fonts, colors, and links which include images that are not attached but loaded when the email is displayed. Some spammers try to exclude words that are normally used in spam messages, fill the message with the nonsense tokens, and getting users to identify messages that contain spam words as non-spam (ham), for instance, word salad, white-out, invisible-ink, camouflage, HTML abuse, the daily news, random words, etc.

Effective spam filters must use multiple techniques to correctly filter messages. The best spam filter for any email account is the person who owns the account. Even as smart as most humans are, spammers try to trick them into reading spam messages that make it pass the filter or into not reporting the spam to the proper authorities, for example, fake legitimacy and sender unknown. Comprehensive discussions on the spammer tricks can be found in many sources such as [14].

This paper presents a method based on artificial immune systems to extract a set of features from email messages that can be used as input for a spam detection system. An artificial immune system (AIS) is a computational model inspired by mammalian immune systems. The main purpose of the immune system is to recognize all cells (or molecules) within the body and categorize those cells as self or nonself by learning through evolution. The harmful nonself elements of particular interest are the pathogens, such as viruses, bacteria, multi-cellular parasites and fungi. Artificial immune systems have been developed for a wide range of applications from data mining to information security [5,6]. In many cases, the applications have produced results comparable to, or better than, other standard techniques.

The rest of this paper is organized as follows. In Section 2, general and AIS-based spam filtering techniques are discussed. Section 3 presents our feature extraction and spam detection approach. In Section 4, the proposed method is evaluated against a standard content-based spam collection and reference systems. Section 5 provides concluding remarks on the research.

II. RELATED WORK

A role of the immune system is to protect our body from infectious agents such as viruses, bacteria, fungi and other parasites. On the surface of these agents are antigens that allow the identification of invading agents (pathogens) by the immune cells and molecules, thus provoking an immune response [9,10]. Recognition in the immune system is performed by lymphocytes. Each lymphocyte expresses receptor molecules of one particular shape on its surface (called antibody). An elaborate genetic mechanism involving combinatorial associations of a number of gene segments underlies the construction of these receptors. The overall immune response involves of three evolutionary methods: gene library evolution generating effective antibody, negative selection eliminating inappropriate antibodies and clonal selection cloning well-performing antibodies [10]. A more complete and accurate description of the immune system can be found in many biology texts.

There are a larger number of techniques for analyzing emails and determining whether they are indeed spam. Due to the fact that the response rate for spam is very low, spammers are forced to send out millions of copies of the same e-mails.

Content analysis techniques analyze the content of inbound emails and focuses on the commercial aspect of spam by detecting suspicious characteristics of legitimate and illegitimate offerings or information requests that spammers try

to hide from spam filters and email users at least until they open the emails. Nowadays, spammers change one or more characters of offensive words in their spam in order to foil content based filters. However, those changes are performed in such a way that human can understand meanings of the words without much difficulties [14], for instance, versions of the word 'Viagra', 'Vi@grA', 'V-iagra!', etc. cannot be detected by conventional spam filters. A number of content analysis techniques have been proposed. Keyword analysis, lexical analysis, bayesian analysis, and heuristic approaches. More filtering techniques and more a comprehensive description of spam filtering techniques can be found in many sources [2,4,14].

Regarding spam detection approaches based on artificial immune systems, Oda and White [12] describe a technique with a collection of detectors are created and combined randomly into new detectors. Digital lymphocytes have a receptor that can bind to more than one email message, through regular expressions. Emails are assigned final scored based on matched lymphocytes and results from other spam detection systems.

III. The Proposed Spam Detection Technique

The proposed spam detection method is a two-step approach. First, a set of message features are extracted from a training set of known spam and non-spam messages. The features are then used as input for a classification model to make a decision on the type (i.e., spam or non-spam) of unknown email messages.

A. *Artificial Immunity-Based Spam Feature Extraction*

1. Antibody generation: an initial set of antibodies is generated from a training set of email messages. The process consists of three parts. A MIME Parser parses values of MIME fields in each email. A HTML Parser selects and eliminates HTML tags. A list of stopwords is used to remove predefined unimportant words. The body and the subject parts of a message are parsed, and terms are identified based on delimited whitespace and stopmarks (".", "?", ";", ":", and "-"). The remaining terms become the initial set of base strings (antibodies).

2. The gene library: The gene library consists of two components: a library of base strings and a library of character matching patterns. A base string is a term found in spam messages whose age is greater than zero with all of its characters converted to small caps. Each base string in the library has an age associated with it. A character matching pattern has the form of: character =~ [$symbol_1$, $symbol_2$, …, $symbol_m$] (expressed here using the Perl's regular expression syntax), for instance a =~ [a, à, á, á, @]. A lymphocyte is represented as a regular expression formed by replacing each character in a base string with the right side of its corresponding character matching pattern, e.g., a base string "viagra" becomes a lymphocyte "vi[a, à, á, á, @]gr[a, à, á, á, @]". These lymphocytes are used to match terms from email messages. Both base strings and character matching rules are dynamically updated (evolving) with every message processed.

3. Learning Features: In feature extraction process (outlined in Fig. 1), lymphocytes matched with terms in spam messages have the age of their corresponding base strings increased by the spam-rate (*s-rate*) while those matched with terms in legitimate (non-spam) messages have the corresponding age decreased by nonspam-rate (*n-rate*). The increment represents the usefulness of the lymphocyte in identifying spam messages. In addition, each base string has its age decreased by the aging rate (*a-rate*) for every message processed. Once the age reaches zero, the base string is removed from the library (i.e., the lymphocyte dies off). Matching of antibodies and strings from emails is performed by edit distance [7] which represents the minimum number of insertions, deletions, and substitutions required to transform one string into the other.

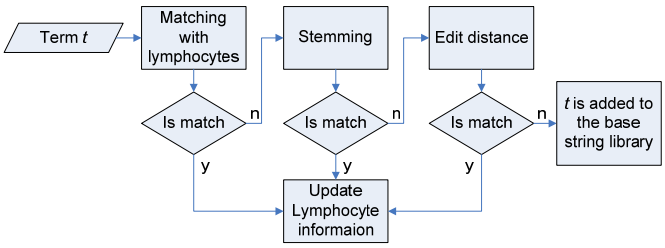

Figure 1. Feature extraction process.

B. *Spam Detection Model*

A Backpropagation neural network (Fig. 2), [13] is used as a spam detection model. It is a structure of small processing units, called neurons, connected in a systematic way. The neural networks used are Backpropagation feed forward neural networks, also known as multilayer perceptrons (MLP). The neurons are arranged in layers. Typically, there is one layer for input neurons (the input layer), one or more hidden layers for non-linear mapping, and one layer for output neurons (the output layer). Each layer is fully interconnected to the following layer.

The connections between neurons have weights associated with them, which determine the strength of influence one neuron has on the other. Information flows from the input layer through the hidden layer(s) to the output layer to generate predictions. By adjusting the connection weights during training to match predictions to target values for specific records, the network "learns" to generate better and better predictions. The computation of a backpropagation neural network consists of two passes: forward pass and backpropagation pass. The description here following.

Forward Pass: Input neurons have their activations set to the values of the encoded input fields. The activation of each neuron in a hidden or output layer is calculated as $a_i = \sigma(\sum_j w_{ij} o_j)$ where a_j is the activation of neuron *i*, *j* is the set of neurons in the preceding layer, w_{ij} is the weight of the connection between neuron *i* and neuron *j*, o_j is the output of

neuron *j*, and $\sigma(x)$ is the logistic transfer function:

$$\sigma(x) = \frac{1}{1+e^{-x}} \quad (1)$$

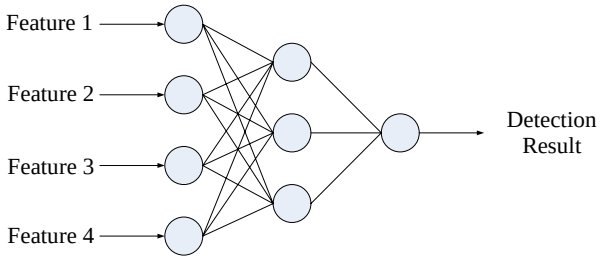

Figure 2. A Backpropagation neural network.

Backpropagation Pass: For each record, information flows through the network to generate a prediction, as described above. The prediction is compared to the target value found in the training data for the current record, and that difference is propagated back through the network to update the weights. To be more precise, the change value Δw for updating the weights is calculated as:

$$\Delta w_{ij}(n+1) = \eta \delta_{pj} o_{pi} + \alpha \Delta w_{ij}(n)$$

where η is the learning rate parameter, δ_{pj} is the propagated error (described below), o_{pi} is the output of neuron *i* for record *p*, α is the momentum parameter, and $\Delta w_{ij}(n)$ is the change value for w_{ij} at the previous cycle.

The value of α is fixed during training, but the value of η varies across cycles of training. η starts at the user-specified initial eta, decreases logarithmically to the value of low eta, reverts to the high eta value, and then decreases again to low eta. The value of η is calculated as:

$$\eta(t) = \eta(t-1) \cdot \exp\left(\log\left(\frac{\eta_{low}}{\eta_{high}} \right) \Big/ d \right) \quad (2)$$

where d is the user-specified number of eta decay cycles. If $\eta(t-1) < \eta_{low}$, then $\eta(t)$ is set to $\eta_{high} \cdot \eta$ continues to cycle thusly until training is complete.

The backpropagated error value δ_{pj} is calculated based on where the connection lies in the network. For connections to output neurons it is calculated as $\delta_{pj} = (t_{pj} - o_{pj}) o_{pj} (1 - o_{pj})$ where t_{pj} is the target value of output j for record p. For the weights that do not connect to the output neurons, δ_{pj} calculations take account of upstream error propagation, as $\delta_{pj} = o_{pj}(1 - o_{pj}) \sum_k \delta_{pk} w_{kj}$ where k is the set of neurons to which neuron *j*'s output is connected, w_{kj} is the weight between the current neuron and neuron *k*, and δ_{pk} is the propagated error for that weight for the current input record.

IV. Performance Evaluation

In this section, a series of experiments is carried out to evaluate our feature extraction technique. The data set used in this study is the SpamAssassin public corpus [15] which is widely used in evaluating spam detection systems. Two main types of settings are of interest: using the pruning phase and not using the pruning phase, (displayed in shaded areas). The pruning phase, *s-rate* and *n-rate* are set for a smooth adjustment of lymphocytes until reaching the number of lymphocytes needed. The remaining lymphocytes become the features used in spam detection systems. Details of all configurations are listed in Table I. If the pruning phase is not performed, living lymphocytes retained from the first phase are ordered by age, and the top required numbers of lymphocytes are selected as the features.

During training, 1,500 spam and 1,500 non-spam messages are used; and in order to measure the performance, 500 spam and 500 non-spam messages are used. Clementine [3], data mining software, is used to create every detection model; 30% of training data is set aside to prevent overfitting during detector model training.

Every configuration is executed 3 times with different initial weightings, each time we measure performance figures (detection rates and miss detection rates), and the average performance across the 3 iterations are calculated and reported.

TABLE I
Feature Extraction Configurations used in the Study

			Training			Pruning		
Configurations	*# Features*	*Initial Age*	*s-rate*	*n-rate*	*d-rate*	*s-rate*	*n-rate*	*d-rate*
Configuration 1	100	60	3	2	1	2	1	1
Configuration 2	150	60	3	2	1	2	1	1
Configuration 3	200	60	3	2	1	2	1	1
Configuration 4	100	60	3	2	1	-	-	-
Configuration 5	150	60	3	2	1	-	-	-
Configuration 6	200	60	3	2	1	-	-	-
Configuration 7	100	60	5	2	1	2	1	1
Configuration 8	150	60	5	2	1	2	1	1
Configuration 9	200	60	5	2	1	2	1	1
Configuration 10	100	60	5	2	1	-	-	-
Configuration 11	150	60	5	2	1	-	-	-
Configuration 12	200	60	5	2	1	-	-	-

TABLE II
Performance of Different Parameter Configurations

	Classification Rate (%)			Misclassification Rate (%)		
Configurations	Spam	Ham	Overall	Spam	Ham	Overall
Configuration 1	79.60	97.60	88.60	20.40	2.40	11.40
Configuration 2	82.00	95.80	88.90	18.00	4.20	11.10
Configuration 3	77.40	96.80	87.10	22.60	3.20	12.90
Configuration 4	79.20	95.40	84.30	20.80	4.60	15.70
Configuration 5	82.60	97.60	86.10	17.40	2.40	13.90
Configuration 6	79.00	96.60	87.80	21.00	3.40	12.20
Configuration 7	80.80	98.20	89.50	19.20	1.80	10.50
Configuration 8	82.60	98.20	90.40	17.40	1.80	9.60
Configuration 9	86.20	99.00	92.40	13.80	1.00	7.60
Configuration 10	80.20	96.20	88.20	19.80	3.80	11.80
Configuration 11	82.40	97.40	89.90	17.60	2.60	10.10
Configuration 12	81.00	97.80	89.40	19.00	2.20	10.60

First, different parameter configurations listed in Table I are studied. The results, in Table II, show that in general pruning gives better performance than not pruning, and the best parameter configuration is Configuration 9 which uses *s-rate* = 5, *n-rate* = 2, the number of lymphocytes = 200, and the pruning phase is applied.

Next, Configuration 9 is studied against three configurations of SpamAssassin. The results are shown in Table III. Note that, an important parameter of SpamAssassin (SA) is threshold with the default value of 5.0, represented as SA (threshold 5.0) in the table, as well as three other threshold values. With the SpamAssassin data, Oda and White [12] report the overall detection rate of 90%, with 84% and 98% spam and non-spam identification rates, respectively. Their work generates 1,000 lymphocytes and takes into account results from other spam detectors in making the decision. We also list their work in Table III and Fig. 3, for reference.

The results show that the proposed method performs well in relation to SpamAssassin, which as discussed in [12] uses over 700 complex heuristic tests to achieve similar results. In addition, Spam Assassin takes about 10 seconds in this environment to determine whether an email is spam, compared to less than a second far our system. Compared to [12], our system gives better performance on the same collection using five times less number of antibodies and not employing results from external detectors.

TABLE III
PERFORMANCE OF SPAMASSASSIN AND THE PROPOSED METHOD

	Classification Rate (%)			Misclassification Rate (%)		
	Spam	Ham	Overall	FN	FP	Overall
SA (Threshold 2.5)	86.80	99.80	92.80	13.20	0.20	7.20
SA (Threshold 4.0)	86.80	99.80	92.80	13.20	0.20	7.20

FN = False Negative FP = False Positive

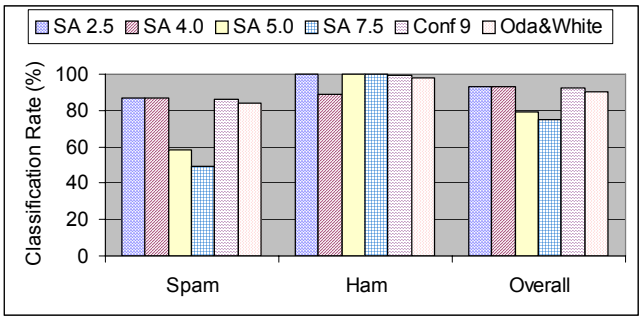

Figure 3. Performance of SpamAssassin and the proposed method.

V. CONCLUSION

This paper presents a feature extraction technique, based on artificial immune systems. Once a set of features is extracted, they are used as inputs to spam detection models. Features are represented as lymphocytes in AIS which are modeled by regular expressions of terms, constructed from base string and character matching rules, from the content of spam messages. The generation, updating, and elimination of lymphocytes are based solely on the content of spam and non-spam messages used in training. Different parameter settings of the method are studied with Backpropagation neural network which is used as spam detection model. The best feature extraction configuration is created by using *s-rate* = 5, *n-rate* = 2, the number of lymphocytes is 200, with the pruning phase applied. Its overall detection rate is 92.4% with the spam and the non-spam classification rates of 86.2% and 99.0%, respectively, which is comparable to more complex systems reported in literatures.

Due to the fact that the proposed method is not dependent upon languages, it is an attractive approach for multilingual spam detection. Since it is adaptive in nature; with a matching adaptive classification model, spam detection systems created can then be adaptive. This capability can be employed to support personalization by providing a base set of lymphocytes and allowing individual users to update their own lymphocytes based on their judgments and experiences with email messages.

Modification Of An Urban Area Okumura-Hata Propagation Model Suitable For Salalah-Oman

Z. Nadir, N. Elfadhil, F. Touati, B. Suhail, M. Jamal, M. Abdulrahman,
Dept of ECE, Sultan Qaboos University
Muscat, Sultanate of Oman
{nadir@squ.edu.om}

Abstract

The path loss, which represents signal attenuation as a positive quantity measured in dB, is defined as the difference (in dB) between the effective transmitted power and the received power, and may or may not include the effect of the antenna gains.

Imprecise propagation models lead to networks with high co-channel interference and a waste of power. In this paper, we aim to adapt a propagation model for Salalah (OMAN) as we examine the applicability of Okumura-Hata model in Oman in GSM frequency band. The study was carried out for urban area, since measurements provided from OmanMobile were about the urban areas. The study helped to design better GSM network for the city area. We will modify the propagation model used in Salalah city. We will accomplish this by investigating the variation in pathloss between the measured and predicted values, according to the Okumura-Hata propagation model for a cell in Salalah city. Then, we intend to modify the Okumura-Hata model according to the results obtained in our investigation. We will then verify our modified model by applying it for other cells and conclude the results. For the purpose the mean square error (MSE) was calculated between measured path loss values and those predicated on basis of Okumura-Hata model for an open area. The MSE is up to 6dB, which is an acceptable value for the signal prediction. Therefore, the model gave a significant difference in an open area that allowed necessary changes to be introduced in the model. That error was minimized by subtracting the calculated MSE (15.31dB) from the original equation of open area for Okumura-Hata model. Modified equation was also verified for another cell in an open area in Oman and gave acceptable results.

Keywords: propagation models. Okumura Hata Model, Pathloss,

I. INTRODUCTION

Mobile communications is currently at its fastest growth period in history; due to enabling technologies, which permit wide, spread deployment. Historically, growth in the mobile communications field has now become slow, and has been linked to technological advancements [1,2]. The need for high quality and high capacity networks, estimating coverage accurately has become extremely important. Therefore, for more accurate design coverage of modern cellular networks, signal strength measurements must be taken into consideration in order to provide an efficient and reliable coverage area. This article addresses the comparisons between the theoretical and the empirical propagation models. It was achieved that, the most extensively used propagation data for mobile communications is Okumura's measurements and this is recognized by the International Telecommunication Union (ITU) [3].

The cellular concept was a major breakthrough in solving the problem of spectral congestion and user's capacity. It offered high capacity with a limited spectrum allocation without any major technological change. The cellular concept is a system level idea in which a single, high power transmitter (large cell) is replaced with many low power transmitters (small cells). The area serviced by a transmitter is called a cell. Each small powered transmitter, also called a base station provides coverage to only a small portion of the service area. The power loss involved in transmission between the base station (BTS) and the mobile station (MS) is known as the path loss and depends particularly on the antenna height, carrier frequency and distance. At higher frequencies the range for a given path loss is reduced, so more cells are required to cover a given area. Base stations close to one another are assigned different groups of channels. So that, all the available channels (in frequency, time and space) are assigned to a relatively small number of neighboring base stations. Neighboring base stations are assigned different groups of channels so that the interference between base stations or interaction between the cells is minimized. As the demand for service increases, the number of base stations may be increased, thereby providing additional capacity with no increase in radio spectrum. The key idea of modern cellular systems is that it is possible to serve the unlimited number of subscribers, distributed over an unlimited area, using only a limited number of channels, by efficient channel reuse. [2]

II. THEORETICAL PROPAGATION MODELS

The propagation models are divided into two basic types; namely: Free space propagation and Plane earth propagation model.

A. Free Space Propagation Model

In free space, the wave is not reflected or absorbed. Ideal propagation implies equal radiation in all directions from the radiating source and propagation to an infinite distance with no degradation. Spreading the power over greater areas causes the attenuation. Equation (1) illustrates how the power flux is calculated.

$$P_d = P_t / 4\pi d^2 \ (W/m^2) \quad (1)$$

Where P_t is known as transmitted power and P_d is the power at a distance d from antenna. If the radiating element is generating a fixed power and this power is spread over an ever-expanding sphere, the energy will be spread more thinly as the sphere expands.

By having identified the power flux density at any point of a given distance from the radiator, if a receiver antenna is placed at this point, the power received by the antenna can be calculated. The formulas for calculating the effective antenna aperture and received power are shown in equations (2) and (3) below. The amount of power 'captured' by the antenna at the required distance d, depends upon the 'effective aperture' of the antenna and the power flux density at the receiving element. Actual power received by the antenna depends on; Aperture of receiving antenna A_o, wavelength of received signal λ, and power flux density at receiving antenna P_d.

Effective area A_e of an isotropic antenna is:

$$A_e = \lambda^2 / 4\pi \quad (2)$$

While power received is:

$$P_r = P_d \times A_e = P_t \times \lambda^2 / (4\pi d)^2 \quad (3)$$

$$P_r \ (dB) = P_t - 20 \log_{10}(4\pi) - 20 \log_{10} (d) + 20 \log_{10} (\lambda)$$

While equation (4) illustrates the path loss (L_p):

$$L_p = \text{Power transmitted } (P_t) - \text{Power received } (P_r) \quad (4)$$

When substituting equation (3) in equation (4), it yields equation (5):

$$L_p(dB) = 20 \log_{10} (4\pi) + 20 \log_{10} (d) - 20 \log_{10} (\lambda) \quad (5)$$

Then substituting (λ (in km) = 0.3 / f (in MHz)) and rationalizing the equation produces the generic free space path loss formula, which is stated in equation (6):

$$L_p(dB) = 32.5 + 20 \log_{10} (d) + 20 \log_{10} (f) \quad (6)$$

B. Plane Earth Propagation Model

The free space propagation model does not consider the effects of propagation over ground. When a radio wave propagates over ground, some of the power will be reflected due to the presence of ground and then received by the receiver. Determining the effect of the reflected power, the free space propagation model is modified and referred to as the 'Plain-Earth' propagation model. This model better represents the true characteristics of radio wave propagation over ground. The plane earth model computes the received signal to be the sum of a direct signal and that reflected from a flat, smooth earth. The relevant input parameters include the antenna heights, the length of the path, the operating frequency and the reflection coefficient of the earth. This coefficient will vary according to the terrain type (e.g. water, desert, wet ground etc). Path Loss Equation for the plane Earth Model is illustrated in equation (7).

$$L_{pe} = 40 \log_{10} (d) - 20 \log_{10} (h_1) - 20 \log_{10} (h_2) \quad (7)$$

Where d represents the path length in meters and h_1 and h_2 are the antenna heights at the base station and the mobile, respectively. The plane earth model in not appropriate for mobile GSM systems as it does not consider the reflections from buildings, multiple propagation or diffraction effects. Furthermore, if the mobile height changes (as it will in practice) then the predicted path loss will also be changed.

III. EMPIRICAL PROPAGATION MODELS

Empirical propagation models will be discussed in this section; among them are Okumura and Hata models.

A. Cellular Propagation Models

The two basic propagation models (free space loss and plane earth loss) would require detailed knowledge of the location, dimension and constitutive parameters of every tree, building, and terrain feature in the area to be covered. This is far too complex to be practical and would yield an unnecessary amount of detail. One appropriate way of accounting for these complex effects is via an empirical model. There are various empirical prediction models among them are, Okumura – Hata model, Cost 231 – Hata model, Cost 231 Walfisch – Ikegami model, Sakagami-Kuboi model. These models depend on location, frequency range and clutter type such as urban, sub-urban and countryside.

B. Okumura's Measurements

Okumura carried out extensive drive test measurements with range of clutter type, frequency, transmitter height, and transmitter power. It states that, the signal strength decreases at much greater rate with distance than that predicted by free space loss, as shown in Fig. 1. [3-5].

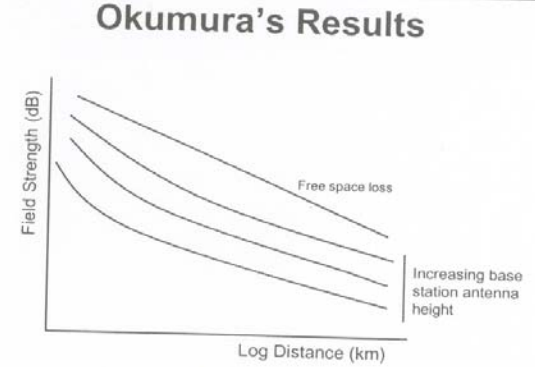

Figure 1: Okumura's Results [3]

C. *Hata's Propagation Model*

Hata model was based on Okumura's field test results and predicted various equations for path loss with different types of clutter. The limitations on Hata Model due to range of test results from carrier frequency *150Mhz to 1500Mhz*, the distance from the base station ranges from 1Km to 20Km, the height of base station antenna (h_b) ranges from 30m to 200m and the height of mobile antenna (h_m) ranges from 1m to 10m. Hata created a number of representative path loss mathematical models for each of the urban, suburban and open country environments, as illustrated in equations (8-10), respectively.

Path Loss for urban clutter:

$$L_p\,(\text{urban}) = 69.55 + 26.16\log(f) - 13.82\log(h_b) - a(h_m) + (44.9 - 6.55\log(h_b))\log(d) \quad (8)$$

$$a(h_m) = (1.1\log(f) - 0.7)h_m - (1.56\log(f) - 0.8) \quad (9)$$

Path loss for suburban clutter:

$$L_p\,(\text{suburban}) = L_p\,(\text{urban}) - 2\{\log(f/28)\}^2 - 5.4 \quad (10)$$

Path loss for the open country is :

$$L_p\,(\text{open country}) = L_p\,(\text{urban}) - 4.78\{\log(f)\}^2 + 18.33\log(f) - 40.94 \quad (11)$$

Hata model is not suitable for micro-cell planning where antenna is below roof height and its maximum carrier frequency is 1500MHz. It is not valid for 1800 MHz and 1900 MHz systems **.**

IV. Results and Discussions

TEMS tools were used to generate measurements of signal strength level for downlink and uplink at coverage areas for a cell in the road of Salalah, OMAN. However, the road of Salalah can be considered as an open area and therefore equations (8), (9) and (11) of Okumura-Hata model were used. After determining the path loss of the practical measurements for each distance, the study was carried on in order to make a comparison between the practical and theoretical values and the result is shown in Fig-2.

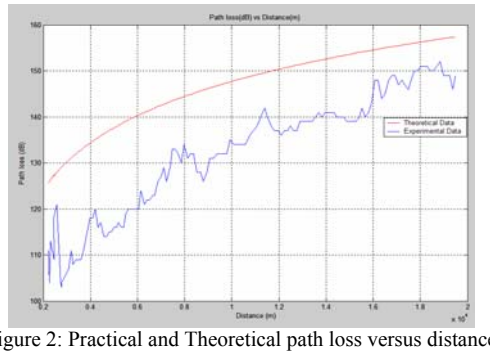

Figure 2: Practical and Theoretical path loss versus distance

From the above plot, the results clearly show that the measured path loss is less than the predicted path loss by a difference varying from 4 to 20 dB. However, there are several reasons which may cause that significant differences. First of all, in Japan there are few areas virtually satisfying the open area conditions; and if any, they are narrow. Because of that reason Okumura selected the value for urban area as standard for open area [5]. Moreover, the geographical situation of Japan is different from that in Oman. In Japan, rain which is the most effective factor that increases the path loss appears most of the time during the year, whereas in Oman most of the time the weather is clear. Therefore the radio signal propagation mechanism is different. Then, mean square error (*MSE*) was calculated between measured path loss value and those predicted by Hata model using the following equation [6]:

$$MSE = \sqrt{\left(\sum (P_m - P_r)^2 / (N-1)\right)} \quad (12)$$

Where;
P_m: Measured path loss (dB)
P_r: Predicted path loss (dB)
N: Number of Measured Data Points

The *MSE* was found 15.3148dB but the acceptable range is up to [6]. Therefore, the *MSE* is subtracted from the Hata equation for open area and the modified equation will be as following:

$$Lp_{\text{Modified}}\,(\text{open area}) = Lp\,(\text{urban}) - 4.78\{\log(f)\}^2 + 18.33\log(f) - 56.26 \quad (13)$$

The modified result of Hata equation in open area is shown in Figure 3 using modified equation and the *MSE* in this case is 5.6193dB, which is acceptable [6].

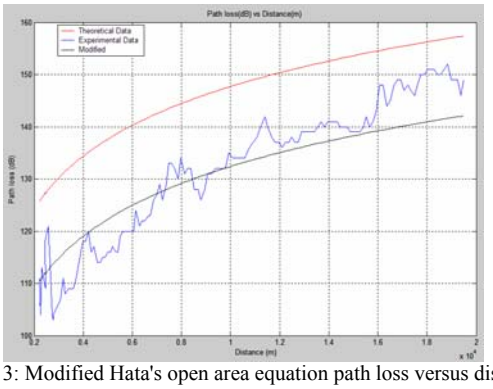

Figure 3: Modified Hata's open area equation path loss versus distance

In order to verify that the modified Hata's open area equation (13) is applicable for other open areas in Oman, another data generated from TEMS tool for another cell in the road of Salalah has been used. Therefore, based on that practical data, the propagation path loss and the distance have been determined and the result is shown in Figure 4.

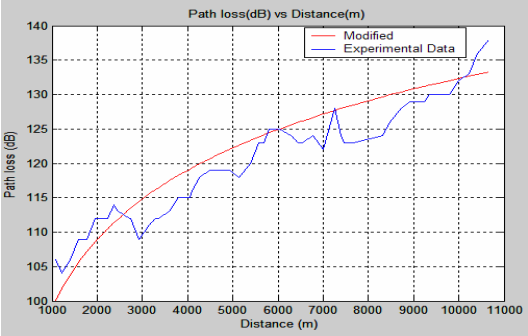

Figure 4: Modified Hata's open area equation path loss versus distance for another cell

By calculating the *MSE* for the second cell, it was found to be (3.2058dB) which is acceptable [6]. Therefore, the modified Hata's open area equation (13) was verified in order to be applicable in other open areas in Oman.

CONCLUSION

Generally, this work was focused for predicting the mean signal strength in different areas and with the signal variability as the mobile moves. However, most propagation models aim to predict the median path loss. But, existing predictions models differ in their applicability over different terrain and environmental conditions. Although there are many predictions methods based on deterministic processes through the availability of improved databases, but the Okumura-Hata model is still mostly used **[7].** That is because of the ITU-R recommendation for its simplicity and its proven reliability.

The effects of terrain situation predicted at 900MHz were analyzed. Results of radio signals propagation measurements for an open area in Oman were compared to those predicted based on Okumura-Hata model. However, the Okumura-Hata propagation model might not be fully adapted in Oman because there is no rain attenuation impact in Oman environment due to lack of rain. Therefore, further improvement of Okumura-Hata model in the open area has been suggested. This improvement was achieved by using mean square error (*MSE*) between measured and predicted path loss values in order to provide sufficient *MSE* for radio prediction The modified equation (13) was verified for a cell in another open area and the *MSE* was found to be 3.21dB which is accepted value for signal predication [6].

The measured data that provided by OmanMobile just covered the open area. Therefore, measurements for other areas (urban and suburban) should be obtained in order to compare all results (urban, suburban and open areas) with the predicted data based on Okumura-Hata model for Oman. Also, if more detailed environmental information is included in the model, better prediction results might be achieved.

ACKNOWLEDGMENT

The authors would like to express their sincere thanks to Mr Juma Al-Naabi, Head, Section of Quality Management – Network Division in OmanMobile Telecommunications Company LLC, without his help, valuable information and support this work could not be accomplished.

***Abstract*-Congestion in VDSL network occurs when congestion builds up in the outgoing network and bandwidth is finite. Shaping mechanisms attempt smooth our this traffic. We used a 'leaky bucket' to achieve traffic shaping. But leaky buckets still have a lot of non-conforming frames. The solution to this problem lies in a backpressure algorithm under which no frames are non-conforming inside a VDSL network frame when congestion has built up. Congested nodes send backpressure feedback to neighboring nodes to inform them of unavailable buffering capacity, and this stops them from forwarding another frames until sufficient buffer becomes available. The potential advantages in backpressure networks are that they do not allow frame dropping. In this paper, we have proposed a backpressure algorithm that aims at detecting violations in parameter negotiation. Evaluation and comparison of backpressure with policing mechanisms, namely Leaky Bucket (LB), has shown that VDSL frames and backpressure help to improve throughputs and non-conforming frames. Backpressure meets its quality-of-service (QoS) requirements when source traffic is at low peak rate.**

KEY WORDS
VDSL network, Traffic shaping mechanism, Backpressure and Congestion Control.

I. INTRODUCTION

The ease and deployment speed of VDSL networks make these systems an option for improving efficiency in personal area networking (e.g., cell phone, laptop, ear phone). VDSL network performance is an important element of QoS and relates to the technical part of the Quality of Service parameters. It covers planning, development, operations and maintenance of the network. This focuses on user observable effects between the service access points. Network performance is focused on technical aspects.

A drawback of VDSL networks as compared wired networks is that they are generally less efficient and unpredictable. VDSL has limited bandwidth, high packet overheads, and is more prone to environmental factors such as obstructions, interference, weather and etc. Other issues related to VDSL network, Quality of Service (QoS) have been the relatively limited bandwidth and higher frame-error rates with high frame overheads. This could potentially limit the use of VDSL networks for delivering traffic for real-time applications such as Voice over IP (VoIP) telephony and multimedia applications. End-users have not expected only the mobility to provide QoS support.

In most VDSL networks, if a network device received more frames than it can forward, the device buffers experience backlog. However, when the buffer has filled up, the device begins to drop frames. This may lead to congestion collapse. This occurs when multiple frame streams are used some of the network resources before being dropped. Subsequent retransmissions use more network resources, resulting in degraded throughput.

An alternative approach is to perform hop by hop flow control, or backpressure at every link. Hop by hop flow control combines two mechanisms. The first is a strict portioning of the available buffer space among active flows, with selective backpressure on a per flow basis. The second is fair queuing to all shared resources by flows within a single network device. The result is twofold: frames are never dropped due to congestion within the network, and the available bandwidth is fairly divided up among all competing active flows. If there is no contention for priorities, each flow has access to the entire bandwidth on each link. However, but when there is such contention, each flow can access a fair share of the bandwidth.

In this paper, we are applying backpressure algorithmic concepts to network queue and evaluating the performance using VDSL network models. There are many previous studies involving policing mechanism [1][2][3], however backpressure algorithm in congestion control over VDSL network is not mentioned. Therefore, we proposed the performance comparison between backpressure and traditional policing mechanisms.

This paper is organized as follows. Section 2 is an overview of the most significant traffic policing mechanisms outlined in the literature. In Section 3 the backpressure algorithm is proposed. In Section 4 we defined the simulation model. Section 5 contains a performance evaluation of the proposed solution and comparison to backpressure, traditional policing mechanisms are presented. In Section 6, presents conclusion and recommendation for future research.

II. DESCRIPTION AND MODELING OF TRAFFIC SHAPING

Traffic shaping allows us to control the smooth rate of traffic sent or received on an interface during the entire active

phase. It must operate in real time. The mechanisms proposed are described in the following sections.

A. Requirement for shaping mechanism

aping mechanism system wants to smooth traffic connections by compromising the performance of other connections, and significantly improves the quality of service(QoS).

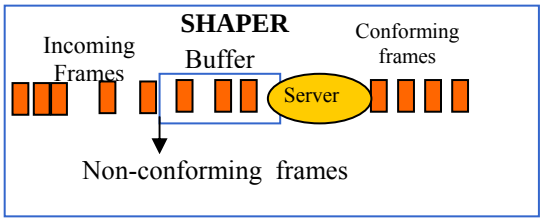

Fig. 1, Traffic shaping mechanism

Traffic shaping mechanism system allows us to ensure that there is a smooth rate of traffic data sent during the active phase and can be operated in real time. The mechanisms proposed is described in following sections.

A.1 Traffic source models

In our simulation, a single source can generate Burst/Silence traffic stream. Burst-periods and Silence-periods are strictly alternating[3].

B. Traffic shaping mechanism system

The Leaky Bucket Mechanism

The VDSL network must provide a large bandwidth and maintain the quality of service (QoS) guarantees. The Leaky Bucket (LB) mechanism (see figure 2) ensures that the source traffic does not exceed the negotiated rate. The bucket-size can be represented as a buffer with capacity N. If the buffer is filled up with frames until it is overflowing, then the frames are dropped. The server operates at a specific data rate, R. The LB is a commonly used for traffic control in high-speed networks

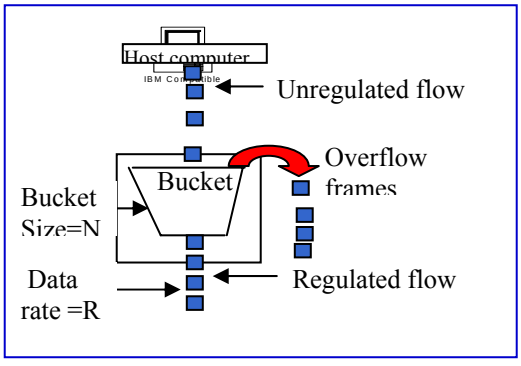

Fig. 2, Leaky bucket mechanism

III. BACKPRESSURE ALGORITHM

Traffic shaping mechanism systems can monitor traffic parameters as defined earlier, such as with peak rates (see Fig. 1). When an arriving frame is detected as being in excess of the receiving system capacity, the network monitor can mark the frame as non-conforming frames. The traffic sh

With backpressure algorithm works like a XON /XOFF techniques to prevent buffer overflows and transient congestion in network. Congestion control is invoked by triggering XON/XOFF flow control messages. The XOFF flow control message is sent upstream when buffer exceeds the upper threshold. When a server receives an XOFF signal, it temporarily stops sending frames until it received an XON signal from the same server, or until the time XOFF message expires. The XON signal is triggered when the buffer at the congested server has descended below the lower threshold.

When frames arrive to a buffer of server, the backpressure algorithm is activated. If the queue is not full and less than the threshold, then the server sends message to source hob that can send a double transmission rate to the receiver hob, and then the frame is transmitted without delay. If the buffer exceeds the upper threshold, the destination hop sends the message to source hop that can reduce it to a half transmission rate [5].

The backpressure algorithm is described as follows .

ALGORITHM

Goal: The goal is the flow control at every link. If the buffer exceeds the upper threshold, then the destination hop sends the message to source hop which can reduce it to a half transmission rate.

```
START_CHCK:
IF Simulation Time Reached THEN GOTO FINISH
ELSE
    { IF Q_DESTN  <  Q_THRESHOLD

     THEN  MARK  AS  HUNGRY FLOW

     ELSE   MARK  AS  RETARDING FLOW

 HUNGRY :  DOUBLE INPUT RATE

              GOTO START_CHECK

 RETARDING : REDUCE INPUT RATE INTO HALF

              GOTO START_CHECK
 }
```

Fig. 3, Backpressure algorithm.

IV. SIMULATION MODEL

The simulation model shown in figure 3 consists of a link processor which transmits frames into the link, and a finite buffer to hold frames. Frame arrival process is random and the inter-arrival time between frames follow a particular distribution function. Furthermore, the arriving frame is given to the link processor, which immediately starts transmitting

the frame; While the buffer is not empty, the link processor retrieves one frame at a time from the buffer in a first-in-first-out (FIFO) order, and transmits it onto the link. The link processor is never idle when there has been a frame waiting in the buffer.

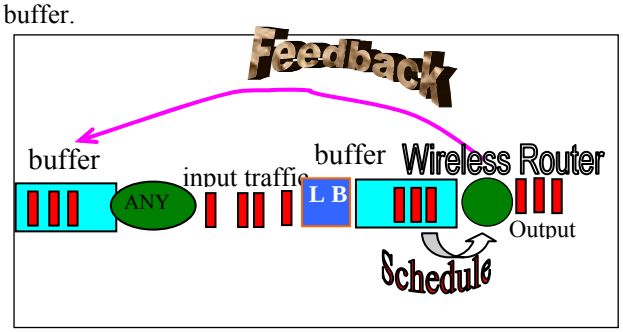

Fig.4, Simulation model

A. Input traffic

This research is mainly confined the discussion of data. Data sources are generally busty in nature whereas voice and video sources can be continuous or busty, it depends on the compression and coding techniques used.

B. Characteristics of queuing network model

There are three components with certain characteristics that must be examined before the simulation models are developed.

B.1 Arrival characteristics

The pattern of arrivals input traffic mostly is characterized as a *Poisson arrival processes*. The probability of the inter-arrival time between event t is defined by the *inter-arrival time probability density function (pdf)*. The following formula gives the resulting probability density function (pdf), where the inter-arrival time t is larger than some value x when the average arrival rate is λ events per second:

$$fx(t) = \begin{cases} e^{-\lambda t}, & for \quad t \geq 0 \\ 0, & for \quad t < 0 \end{cases}$$

$$p(t \leq x) = Fx(x) = \int_0^x e^{-\lambda x} dx = 1 - \lambda e^{-\lambda x}$$

$$p(t > x) = 1 - Fx(x) = \lambda e^{-\lambda x}$$

In this paper, we adopt the ON/OFF busty model [5], [6].

B.2 Service facility characteristics

In this paper, service times are randomly distributed by the *exponential probability distribution*. This is a mathematically convenient assumption if arrival rates are Poisson distributed. In order to examine the traffic congestion of output in VDSL downstream link (15Mbps) [7], the service time in the simulation model is specified by the speed of output link, given that a service time is 216 μs per frame where the frame size is 405 bytes [8].

V. RESULTS AND ANALYSIS

The comparison between backpressure (BP) and existing policing mechanism (LB, JW and TJW) is shown in figure 5-7.

A. The comparison between backpressure scheme and traditional policing mechanism.

This section shows simulation results from backpressure algorithms and traditional policing mechanism, and BP and LB performance are compared. The input frames (frame rate varies from 5 Mbps to 55 Mbps) with burst/silence ratio of 300:500 performed simulation results as shown in Figure 5. It clearly shows that the throughput of LB scheme is far better than the BP scheme. Throughput is one of factor of QoS to help guarantee a higher reliability of network performance. In conclusion, If source traffic is lower than the server performance (15 Mbps) then the throughput of BP is equal to LB.

In figure 6, the simulation results work in the sense that BP will produce non-conforming frames compared to traditional policing mechanism schemes. In other words, we can help conserve the conforming frames by reducing the number of non-conforming frames. A regular network may cause a poor QoS by higher non-conforming or dropped frames. The quality of telecommunication traffics non-conforming frame impact services and the efficient management of maintenance resources.

In figure 7, the simulation result determines greater utilization of backpressure algorithm comparing to traditional policing mechanisms with burst/silence ratio of 300:500. It is not problem when network congestion because the utilization is less than 80%.

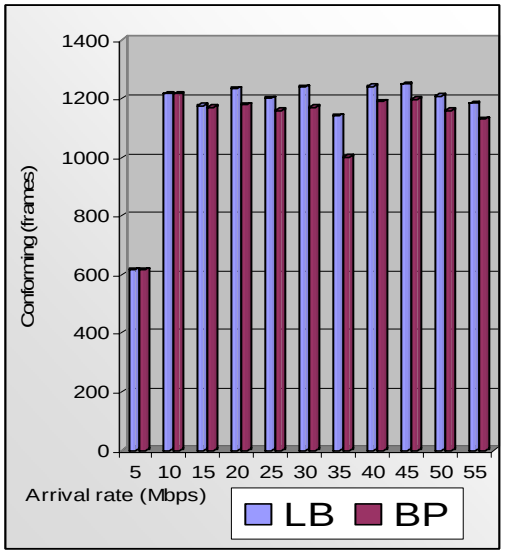

Fig. 5, illustrates comparison between conforming frame in BP and LB at burst : silence = 300:500

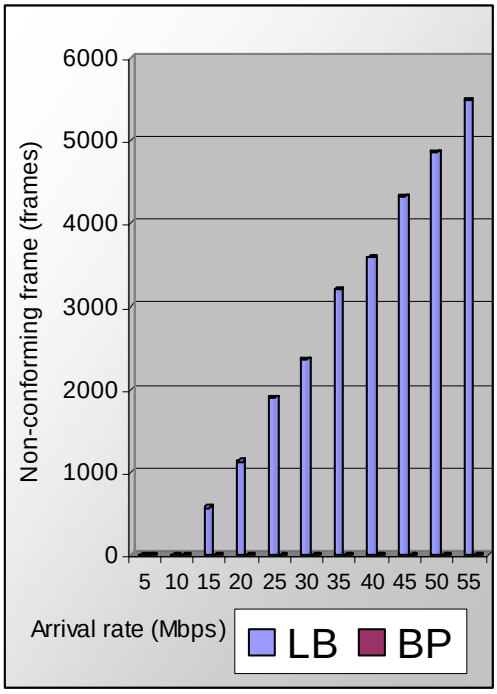

Fig. 6, illustrates comparison between non-conforming frame in BP and LB at burst : silence = 300:500

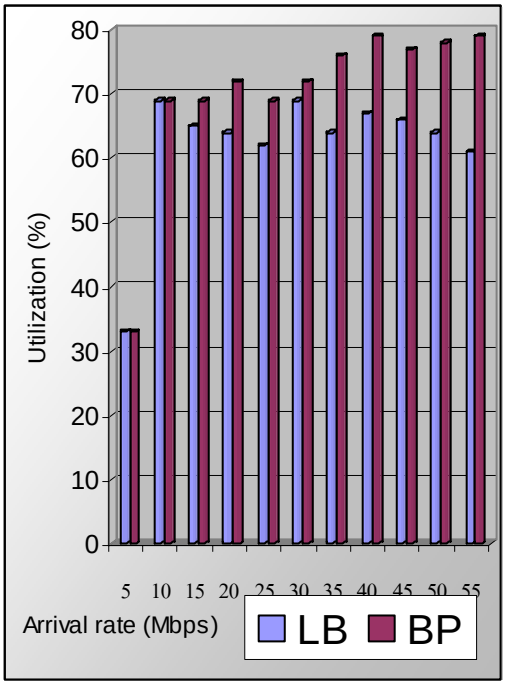

Fig. 7, illustrates the utilization comparison between BP, and LB at burst : silence = 300:500.

VI. Conclusions And Recommendations For Future Research

In this paper, we carried out a comprehensive study to investigate the performance of a backpressure scheme (BP) with a selected Leaky Bucket (LB) traffic shaping mechanism with fixed types of traffic. The study was accomplished through a simulation after developing an analytical queuing model.

We found that the BP within a non conforming frame outperforming LB. In our experience, if source traffics is lower than 20 Mbps because the data rate of server is 15 Mbps, the backpressure is the best in terms of throughput and non-conforming frames. BP is not problem about network congestion because the utilization is less than 80%.

BP meets its quality-of-service (QoS) requirements for VDSL network that have been relatively bandwidth and less delay time so it is suitable for telecommunication traffics.

In our future work, we will focus on the investigation of fuzzy control queuing systems in traffic shaping mechanisms.

Multicast Improvement Bandwidth Utilization in Inter-ring RPR Topology

Wuttichai Kwanmetakun Pisai Setthawong Surat Tanterdtid
wuttihchaikwn@au.edu pisai@ieee.org surat.t@egat.co.th
Department of Telecommunications Science, Faculty of Science and Technology
Assumption University, Thailand 10240

***Abstract*-The IEEE 802.17 Standard, or Resilient Packet Ring (RPR) [1] was standardized in September 2004. Research on inter-ring traffic in RPR is a new development for expanding of the RPR ring by using bridge for interconnection. The standard multicast traffic is treated like broadcast traffic because it is source striped so the bandwidth is wasted from the last destination to the source. This paper presents the algorithm to control the multicast in inter-ring traffic to increase the bandwidth utilization. Our algorithm handles the multicast group to collect the members and distribute the multicast packets to the members. To control the striped multicast packets on the last destination in the local or remote ring by time-to-live (TTL) from enhanced topology discovery [3]. The OMNet++ [3] is used as simulator to test the proposed method and the results are compared with the Standard RPR. The results show that the bandwidth utilization of inter-ring RPR network is improved with the proposed solution, the degree of improvement depending on the location of the multicast members.**

I. INTRODUCTION

Resilient Packet Rings (RPR) [1] is a dual ring topology in which traffic is rotated in opposite directions on each ring; the inner ring is clockwise and the outer ring is counter-clockwise. RPR supports fiber optic and multi-packet platform such as the Synchronous Optical Network (SONET) [4] and the Ethernet frames [5]. Topology discovery (TD) is an important mechanism in RPR in order to exchange the information within the ring and complete topology's table of each node in the RPR network. Topology discovery is triggered periodically or by changes in the RPR network topology. Spatial reuse is used in RPR which allows the available bandwidth of the ring to transmit unicast traffic at the same time. Spatial reuse is made possible by the use of destination striped so it is used only for unicast traffic.

Inter-ring RPR is created by using bridge to expand the standard RPR as show in Fig 1. For inter-ring RPR, the functionalities of bridge provide to support the RPR network, such as Spanning Tree Algorithm (STA) [6].

On the other hand, multicast packets are striped at the source like broadcast traffic. This is known as source striping. Previous research [8] on multicasting was developed by using destination striped to remove the packet before it reaches the source. The time-to-live (TTL) value of multicast packet, which was from the topology discovery's information, will stripe the packet at the last member of the multicast group.

The standard of RPR and the existing literatures do not provided any ideas to support efficient multicast in the inter-ring RPR network. A novel idea is needed to reduce the duplicated traffic, such as unicast traffics that transmit for receivers. Broadcasting in the inter-ring RPR network affects the bandwidth utilization because if the broadcast packet is flooded through the bridges to other rings, the bandwidth utilization is dropped by the unwanted traffic.

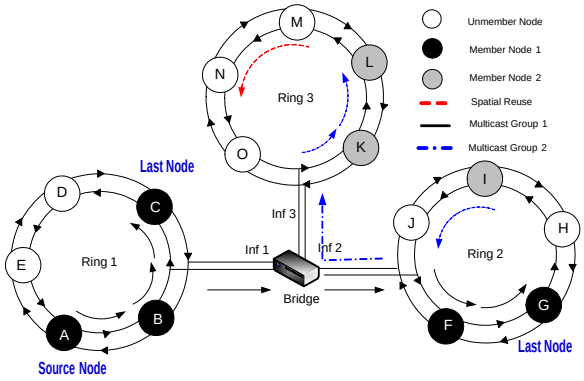

Fig 1. Node A sends the multicast packet to the members in the 3 inter-ring RPR which were connected by a single bridge.

The proposed algorithm denied the flooding from the multicast packet of the standard bridge to the rings which was no multicast member. The multicast traffic in the remote is striped at the last destination nodes of the multicast group.

The structure of this paper is organized as follows; the explanation of the multicast in the inter-ring RPR network is in the section 2. In section 3, the proposed algorithm and enhancement is illustrated using diagram. The remainder of this paper, the result and analyze of simulation, and conclusion are in section 4 and 5 respectively.

II. MULTICAST IN THE INTER-RING RPR TOPOLOGY

To implement the efficient multicast for the inter-ring RPR topology requires many developments to improve the standard of RPR and bridging. Enhanced bridging [3] is the new improvement for updating the performance of RPR to map the local address and the remote address, so the packet is forwarded directly to the remote destination. By Spatial Reuse Control Sublayer (SRCS) [7], the remote address is mapped to the local's table (bridge address) and compared to the global and local source address. The SRCS table is used to decide the next bridge in order to reach the destination bridge by using the bridge's table forward directly the destination address.

Enhanced Topology Discovery (ETD) and Enhanced Spanning Tree Algorithm (ESTA) [2] improve RPR to work more effectively. Topology Discovery is modified by adding

the bridge's indicator in the *TypeLengthValue* field for nodes to forward to other RPR rings directly. ESTA makes enhancements to the stage that information is interchanged between the bridges. By checking the best configuration for information interchange, if the ESPA message is not the last updated, the bridge will append its information and send to other bridges. When both tables are completed, STA and TD, the sender can forward the packet to destination across the bridge.

According to the IEEE 802.17 Standard [1], multicast packets use the MAC address to identify the multicast group within the destination address field. To transmit the packet in RPR, there are 2 types: 1) unidirectional multicast: the packet is transmitted on the chosen ringlet and the packet is striped at the source, and 2) bi-directional multicast: the packet is transmitted on both ringlets and the cleave point is end point for preventing the packet overlap. The RPR Media Access Control (MAC) Client sets the TTL value to control the cleave point.

For local RPR multicast [8], the best choice to use is identified from the location of the adjacent member node. If the closest node to the sender is too far, unidirectional multicast is chosen. If the gap between the adjacent members are very large, the sender can decide the node in the middle gap is the cleave point and bidirectional multicast is used.

Multicast in the Inter-ring RPR is not as simple. To apply the algorithm of the local RPR for the Inter-rings is more complicated. The nature of Multicast in Inter-ring is to increase efficiency by decreasing the unwanted traffic due to flooding from the bridges.

III. PROPOSED SOLUTION

The proposed solution focuses on increasing the bandwidth utilization for Multicasting via Inter-ring RPR. The standard multicast packet was striped at the source, so the algorithm set the priority of the striped packet depends on the TTL of last member in each ring. The TTL is limited to the last member of multicast, such that the bandwidth between the last member and the source node allows for spatial reuse.

The multicast of inter-ring RPR is more complicated because it has the bridge that uses the ETD and ESPA to improve the standard RPR to reduce the bridge's flooding. We modify the topology discovery in the *TypeLenghtValu*e (1byte) field in order to collect the multicast member's address, which is called the Registrar Massages (RM). The packet identification is set for the multicasting identification. So anytime, the source is sending the multicast packet, it has to flood the RM to collect the members. The bridge acts like the source to remote of each rings so if a ring has no members, the bridge does not forward to its interfaces on that ring.

A. Multicast Registration

Initially, the sender floods the RM to all nodes in the network. The bridge receives the packet and floods to every interface except the incoming interface. The number of the RM is set to the identities of the multicast group automatically. The interested nodes receive the packet and will respond to the sender by replying with a unicast packet.

For the nodes in the remote ring, the interested nodes reply to the bridge first. The bridge will create the bridge's forward table from the messages information by mapping the multicast and the adjacent bridge, after that it will forward to the sender.

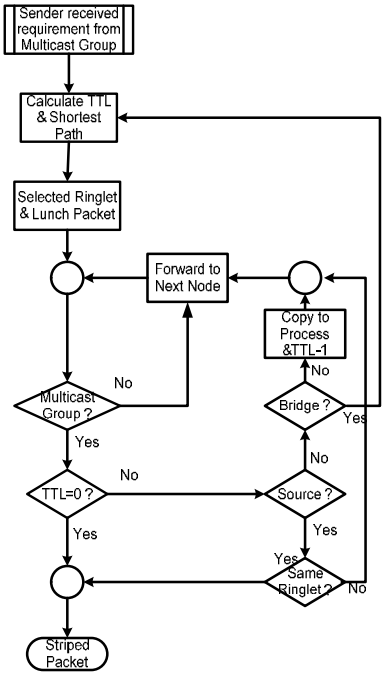

Fig 2. Flow chart of the multicast distribution is represented the proposed algorithm.

B. Multicast Distribution

The algorithm for multicast distribution is shown in Fig 2.When the multicast member's list is completed, the sender calculates the TTL to reach the last member node on the designated ringlet. The TTL of the multicast packet is decreased by each member node by 1 and the packet is copied to be processed at the MAC client layer. Other non-member nodes forward the multicast packet to the next node without decreasing the TTL. The last multicast member will decrease the TTL to zero and the packet is striped.

For Inter-ring RPR, when the bridge receives the multicast packet, it will check the destination from the bridge's forward table. The bridge will forward the multicast packet to the interface that the destination is on. After forwarding the packet to the other RRP rings, the bridge will re-calculate the TTL of the packet, by the bridge acting like the virtual source in the remote site so the same steps as the local ring can be repeated within each ring. If there are no multicast members in the remote site, the bridge will forward the packet to the next node in the local ring. The traffic in other RPR ring is not disturbed from the unwanted packet. This allows those parts of ring to create the spatial reuse traffic concurrently.

The algorithm is implemented to the nodes and the bridges to recognize the multicast group. In the case of the small network or single RPR ring, the enhanced multicast uses more

time in the registration period when it is compared with the standard multicast. On the other hand, the large network or inter-ring RPR, the enhanced multicast is very more valuable in the case of the video conference or the group distribution application because the unwanted traffic is avoided. We use the unused field of the frame format to implement so it does not require upgrading for any hardware or software.

IV. Simulation and Analysis of Proposed Solution

We conducted the OMNet++ simulator by configuring the parameters as shown in Table I.

TABLE I
CONFIGURATION PARAMETERS FOR OMNET++ SIMULATION

Parameter	Value
Link Capacities	2.4 Gbps(OC-48)
Packet Size	1,512 bytes data
Fairness Mode	Aggressive
Transit Buffer Size	6,144 bytes(4packets)
Link Delay	0.1ms

Initially, all nodes attach their information to the topology discovery message and flood to all nodes for completed topology's table and bridge's table. The topology discovery's table, includes collecting the multicasting member, is then created. In the simulation, we show the bandwidth utilization of multicast in inter-ring RPR, based on the following scenarios. Scenario 1 is measured time (ms) versus the link utilization of ring. By node A is a source node, after completed the multicast address's list, it calculated the TTL from the topology discovery's table for striped at the last destination.

For scenario 1, we measure the result of link utilization of each ring and compare with the standard multicasting. We can define the link utilization equation as:

$$Link\ Utilization = (TTL/Hop\ Count) * 100 \quad (1)$$

where *TTL* is the time-to-live of multicast, *Hop Count* is the number of passed node.

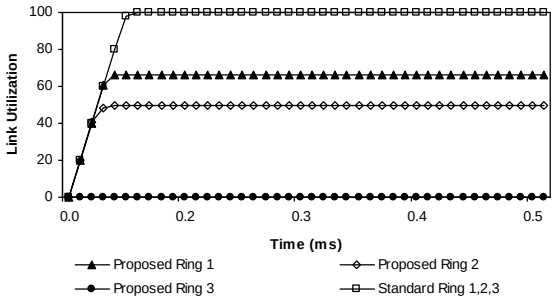

Fig 3. Graph of the link utilization in each rings for proposed multicast compare standard multicast.

The result of the simulation depends on the member's location as shown in Fig 3. The link utilization of the standard multicast in the ring 1, 2 and 3 is 100 percent from the source striped. When we applied our proposed algorithm, which was striped at destination, the graph of ring 1 will drop to approximate 66 percents from 3 members. The link utilization of the ring 2 is 50 percents from the 2 members in 5 nodes. The last ring 3 is 0 percents because no member is in the ring. When the link utilization was decreased, the bandwidth of each rings are more available to create other individual traffic so our proposed multicast use less bandwidth than standard multicast.

Next, we relocate the members in the ring 1and 2 by moving node C to D and G to I, in order to measure the link utilization and compare with the result in the previous scenario. The result of the link utilization in ring 1 and 2 increased by approximately 83.33 percent from the same number of members as in the previous scenario, as shown in Fig 4.

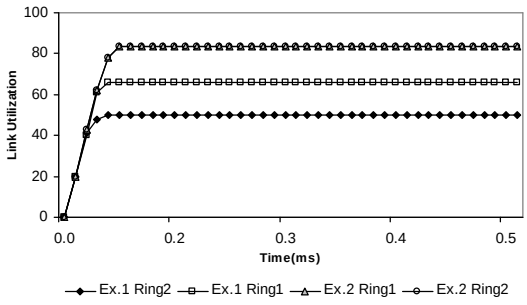

Fig 4. Graph of the link utilization, after relocation.

After we changed the node position, it affect to the link utilization which was increased, so the location of members is a major factor for the bandwidth usage.

For scenario 2, we use the topology shown Fig 1. We set the multicast group 1 as 200 Mbps, another multicast group as 400 Mbps and spatial reuse node M to N as maximum of bandwidth for testing the throughput of multicast traffic node M.

The result of the throughput at node M before applying the proposed multicast is 200 Mbps for multicast group 1's traffic, 400 Mbps for multicast group 2's traffic and the traffic of spatial reuse is 1.8 Gbps. The results of the proposed solution are shown in Fig 5. The throughput of spatial reuse is 2.4 Gbps that it is the maximum bandwidth of link capacity.

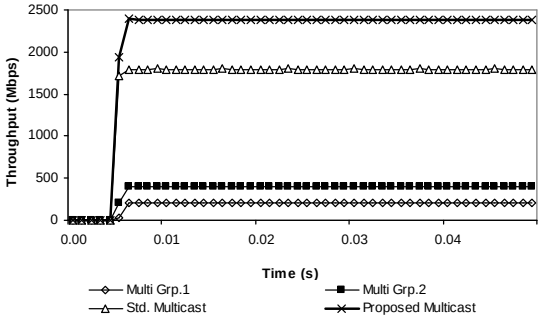

Fig 5. Graph of the throughput at node N compare the standard multicast and proposed multicast.

For scenario 3 in Fig 6, we applied the multicast traffic to the 3 inter-ring RPR with dual bridges. In this scenario, the traffic of ring 2 had to use for the route reach to the members in ring 3 so the traffic should limit less as possible and does not disturb the traffic in the ring 2.

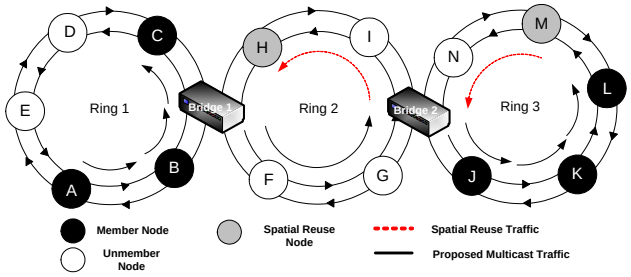

Fig 6. Node A sends the multicast packet to the members in the 3 RPR rings that were connected by dual bridges.

First, we start to transmit the multicast packet by using the standard multicast, after 0.05s, node M would transmit the spatial reuse traffic to node H. We measured the transmit rate at node H. For the results, the transmit rate of the standard multicast used full of bandwidth available but after 0.05s, the transmit rate dropped 50 percent from fairness mechanism for sharing the traffic with the spatial reuse as show at Fig 7.

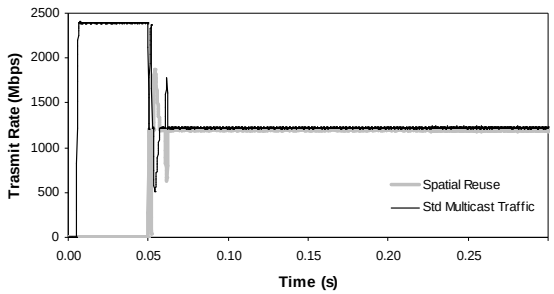

Fig 7. Graph of the transmit rate of standard multicast after the spatial reuse transmitted by measuring at node H.

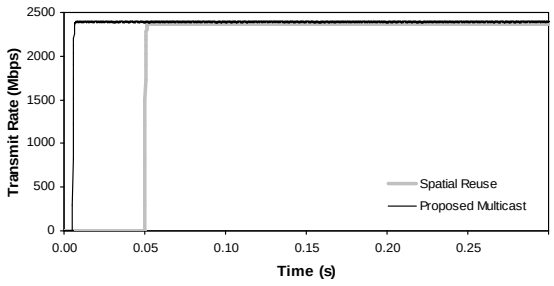

Fig 8. Graph of transmit rate of the proposed multicast after the spatial reuse transmitted by measuring at node H.

We also applied the proposed multicast instead the standard multicast and observe the transmit rate of the spatial reuse from nodes M to H. The transmit rate of spatial reuse doesn't drop during the multicast traffic as shown in Fig 8. When we compare the results of the 2 simulations, the proposed multicast avoid the multicast traffic to share the bandwidth of the spatial reuse so the transmit rate of spatial was full of bandwidth.

V. Conclusion

The simulation's results of the proposed multicast compared with the standard multicast show the increased bandwidth utilization in the inter-ring RPR from the lower link utilization and the throughput of the spatial reuse was full of link capacities during the multicasting. The proposed multicast algorithm uses less bandwidth than the standard multicast in the local and remote ring because the multicast traffic is limited at the last destination of each ring. The location of the member nodes impact the bandwidth usage of our multicast because we use only unidirectional multicast; nevertheless, it still better than the standard multicast. The cost upgrades of current RPR hardware and software is not required for implement the multicast in inter-ring RPR.

***Abstract*- We present another scheme, QoS based on Genetic Algorithms (QGAs), for finding the optimum route for wireless mesh networks. Our scheme was evaluated, based upon a critical factor as wireless channel quality, to decide whether each packet is successfully received and to define quality of service for improving the link quality and quantity in determining path. Simulation results show that our scheme outperforms with the original. Moreover, the time period of transmission by QGAs is less than the original when the packet size is higher or the population size is enlarging.**

Keywords: **Quality of Service, Genetic Algorithms, Optimum Routing, Wireless Mesh Network**

I. INTRODUCTION

Wireless mesh network (WMN) has grown considerably in popularity based on its several advantages in both metropolitan and rural applications, as showed in Fig. 1. This kind of network seeks to build a resilient and high performance infrastructure to provide users permeable Internet access. In a mesh network, each client accesses a local high speed access point (HAP), and multiple stationary HAPs communicate with one another over the wireless channel and form a multihop, wireless backbone for data delivery. This backbone ultimately forwards user traffic to a few gateway APs (GAPs) that additionally connect to the Internet via a wired connection or perhaps a WiMax link. Wireless devices have maximum utility since they can be used "anywhere at anytime".

The goal of WMNs is to process and forward packet data to other nodes and/or gateway. Therefore, a routing service is essential to WMNs applications. Much of recent work on wireless routing has been focusing on understanding the characteristics of the path performance metrics for finding the shortest path such as Dynamic Source Routing (DSR) [1], and Ad Hoc On-Demand Distance Vector Routing (AODV) [2]. Less attention has been paid to finding high-quality path in the face of lossy wireless links [3].

Nowadays, path optimum problem can be solved by many Artificial Intelligent (AI) techniques such as GAs, Tabu Search (TS), Evaluation Programming (EP), and etc [4]. As a result, a study on these AI techniques with speech recognition [5] is very interesting. GAs is chosen in this paper because (1) GAs can find nearly the optimum solution even for a large scale problem, and (2) GAs is simple to implement and understand.

In this paper, we present another scheme of the radio wireless mesh network, which is QoS metrics like desired

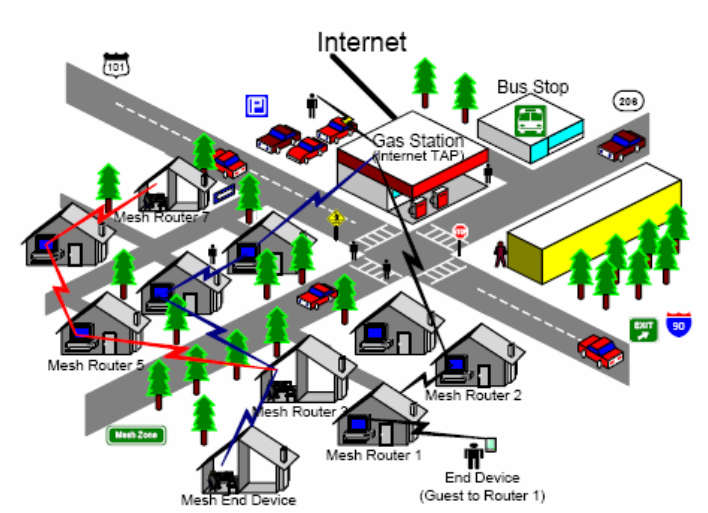

Fig.1: WMNs for metropolitan area networks

signal to noise ratio (S/N), packet loss, utilization and reliability of link in the path selection process to reduce a processing time and increase more accuracy before using GAs process to find an optimum route.

This paper is divided into 5 parts. The introduction is described in section I. The background and the system model are presented in section II and III respectively; whereas, the simulation results are presented in the section IV. Finally, our conclusion is given at the end of this paper.

II. Background

This section describes the wireless network architectures being focused on this paper, and provides a discussion of the Wireless link quality, Quality of Service, and Genetic Algorithms for wireless routing.

A. Wireless Mesh Network

Wireless mesh network is a mesh networking implemented over a Wireless LAN. This type of the Internet infrastructure is decentralized (with no central service provider), relatively inexpensive, and very reliable and resilient. Each node needs only transmission to the adjacent node. Nodes act as repeaters to transmit data from one node to another, allowing the extension of communications over distances, especially over rough or difficult terrain. Mesh networks are also extremely reliable as each node is connected to several other nodes. If one

node drops out of the network, due to hardware failure or any other reasons, its neighbors simply find another route. Extra capacity can be installed by simply adding more nodes. Mesh networks may involve either fixed or mobile devices. The solutions are as diverse as communications in difficult environments such as emergency situations, tunnels and oil rigs to battlefield surveillance and high speed mobile video applications on board public transport or real time racing car telemetry.

B. Wireless Link Quality

The signal strength received form transmitter is important for wireless systems. The loss in signal strength affected from several factor such as noise interference, fading, attenuation, and etc. Many wireless channel models have been proposed to predict the average received signal power. In this paper, we use the free space propagation model to predict received signal strength for the near sight and plane earth propagation model for the far sight. The received signal power (*Pr*) can be characterized as follow.

$$P_r = \begin{cases} \dfrac{P_t \times G_t \times G_r \times \lambda^2}{(4\times\pi)^2 \times d^2 \times L} & , \quad d \le \dfrac{4\times\pi\times H_r \times H_t}{\lambda} \\ P_t \times G_t \times G_r \times \left(\dfrac{H_r \times H_t}{d^2}\right)^2 & , \quad d > \dfrac{4\times\pi\times H_r \times H_t}{\lambda} \end{cases} \qquad (1)$$

From the equation, *Pt* is the transmitted power, *Gt* and *Gr* are the antenna gains at the transmitter and receiver, respectively, *d* is the distance between transmitter and receiver in meter, *Ht* and *Hr* are the heights of the transmitter and receiver, respectively, *L* is the system loss factor not related to propagation (In this paper, *L*=1), and λ is the wavelength in the meter.

The bit error rate (BER) of wireless link is resolute by link quality, modulation and code scheme. The link quality can be represented by signal to noise ratio (S/N) of packet at the receiver. Thus, BER of wireless channel is determined by SNR and modulation scheme or transmission rate. The modulations perform the general relationship between *BER* and *SNR* by the following equation

$$BER \; \alpha \; erfc(\sqrt{C \times SNR}) \quad , \quad SNR = 10 \times \log\left(\frac{P_r}{N}\right) \qquad (2)$$

where *BER* is bit error rate, *erfc (x)* is complementary function, *C* is constant, *Pr* is received signal power which derived from equation 1, and *N* is noise power.

The re-transmission is the factor for network performance with mention in IEEE802.11. When a transmitter send data packets to receiver and does not receive acknowledgments, the transmitter must perform re-transmission packet again. The classifications of the re-transmission have 2 modes, Hop-by-Hop Re-transmission (HHR) and End-to-End Re-transmission (EER). In this paper, we consider the HHR scheme because it is suitable for the characteristic of wireless mesh network such as having low number of packet re-transmission than the EER scheme, and implies a shortest time.

C. Quality of Service

Quality of Service (QoS) refers to the capability of a network to provide better service to selected network traffic over various technologies, including Frame Relay, Asynchronous Transfer Mode (ATM), Ethernet and 802.1 networks, SONET, and IP-routed networks that may use any or all of these underlying technologies [6]. The primary goal of QoS is to provide priority including dedicated bandwidth, controlled jitter and latency (required by some real-time and interactive traffic), and improved loss characteristics. The notion of QoS has been proposed to capture the qualitatively or quantitatively defined performance contract between the service provider and the user applications [7]. The basic function of QoS routing is to find a network path which satisfies the given constraints. In addition, our QoS routing algorithms consider the optimization of resource utilization and link reliability.

D. Genetic Algorithms

Genetic Algorithms (GAs) are adaptive heuristic random search algorithms premised on the evolutionary ideas of natural selection and genetics. The search is usually done with a group or population of binary strings, which are encoded forms of the decision variables. Each string is analogous to a chromosome and each binary bit is analogous to a gene on that chromosome. There are three operators used in the simple GA, selection, crossover, and mutation. Each having the following specific roles:

- Selection: exponentially spreads, over generations, above average fitted chromosomes by allowing them more offspring in next generations.
- Crossover: exploits genetic materials of the current population by breeding most interesting strings.
- Mutation: introduces diversity in population by flipping randomly chosen genes.

Using these operations, more fit members of the population are created over time and the population evolves to optimal or near optimal solutions.

III. System Model

In this paper, we simulate the connecting channel between source node and destination node of mesh topology over wireless communication system. The purpose is to achieve the most appropriate route for sending and receiving packet data. The proposed approach and process are as follows.

1. Individual routes of hop from QoS are determined to be utilized as candidate links prior to the process of GAs. In order to select a route for data transmission, the most important thing to be considered is the quality of the chosen route as it is able to be indicated by the following factors.

- BER: In case a route exhibits a large number of bit errors, it is considered poor quality. Additionally, more time is consumed for re-transmission.
- S/N: Signal strength received is compared to Noise power. A route exhibits low S/N value indicates the occurrence of noise interference of received data, resulted in eccentric signal.

Consequently, more time and energy are needed for re-transmission to obtain accurate data.

- Utilization: This factor considers the number of users of each route. A route with high volume of users is affected with the delay of data due mainly to the limitation of resource allocated to high utilization. Therefore, the route ought to be avoided.
- Link Reliability: This factor is considered to be significant for the selection of appropriate route owing to the fact that there are high tendencies of a route to confront with link down. As a consequence, although other factors prove effective, the opportunity of a successful transmission of data via the link is relatively low.

2. After obtaining the determined Link candidates in accordance with the defined criteria, the links, later, are evaluated to find the best route for transmission of data from source node to destination node by GAs, using Fitness Function under the condition of "minimum delay route" as shown in equation 3 as follow

$$Min\,T(L) = \sum_{i=1}^{M+N} \sum_{j=1}^{M+N} C_{ij} X_{ijk} + T_{re-tran} \qquad (3)$$

where *T(L)* is the period of time for a success of send-receive packet data from source node to destination node.

Cij is the period of time for a success of send-receive packet data between i node to j node.

$$X_{ijk} = \begin{cases} 1 & ,if\ link\ i,\ j\ is\ concluded\ in\ tour\ k \\ 0 & ,otherwise \end{cases}$$

N is number of locations to be visited

M is number of tours

$T_{re\text{-}tran}$ = time period for re-transmission

Fig. 2 shows the flow chart of the proposed QGAs algorithm. The characteristics of the algorithm are summarized as follows:

1) Set model parameter for QoS and error probability obtained from connecting channel as the initial distance, utilization and link reliability, respectively.
2) Create an initial population by randomly generating a set of feasible solution according to our scheme.
3) Determine the fitness function of each number in the population.
4) Apply GA operators to generate new population as mutation, crossover and reproduction, respectively.
5) Compare the results of all generation and choose the best ones.

IV. Simulation Results

We consider a mesh network topology with 50 nodes randomly placed over a 1000 x 1000 m^2, each node randomly positioned with communication range less than 120 meters. We perform experiments transmission packet as 1,000 packets with the sizes of data packets varying from 1,000, 2,000, 3,000 and 4,000 bits/packet. The physical radio characteristic of the transmission bit rate is 54 Mbps referred to IEEE802.11.

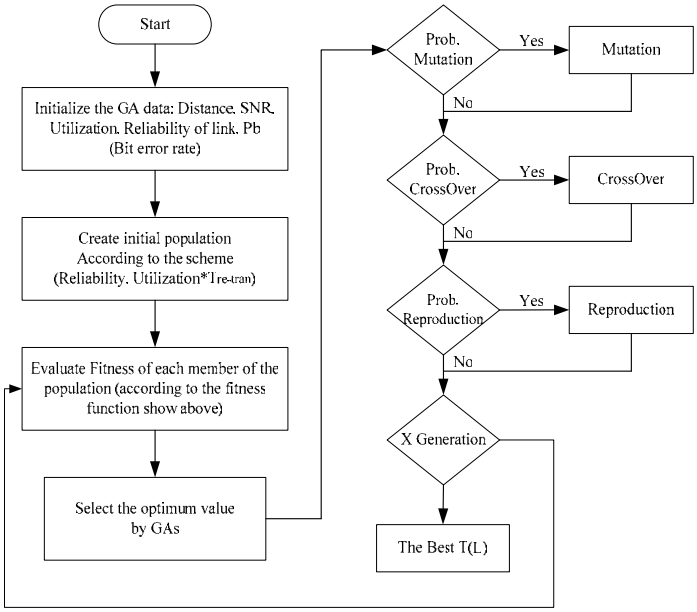

Fig. 2: Flow chart of the proposed QGAs Algorithm

In our simulated situation, we implement the link quality which uses the packet error probability to resolve whether or not each packet is received successfully based on the BER and packet length inferred by SNR at the receiver. Moreover, we consider about the QoS (Utilization and link reliability) for the path selection before using GAs process as well. The initial values of all factors are shown in Table 1.

For the GA parameters, the population size is 50, the value of parameter that optimizes the algorithm's performance as number of generation is 50, the probability of mutation and crossover are 0.5 and 0.75, respectively. The length of connections is 10 nodes.

The performance metrics that we have considered are the minimum delay routes from both of path finding time and transmission time.

Figure 3 illustrates the delay time (Fitness function) with the varied data packet sizes as 1,000, 2,000, 3,000 and 4,000 bits, respectively from both of our scheme and the original. It also shows a verifiable performance for our scenarios, especially for the 80% performance route; the link quality is affected the network connectivity. This implies that QGAs uses more number of hops to avoid the path consist of links having high

Table 1
Initial parameter in random scenario

Utilization (transaction/path)	1-54
Link Reliability (%)	0-100
SNR	0-20
Distance (m)	20-120
Simulation time (min)	2

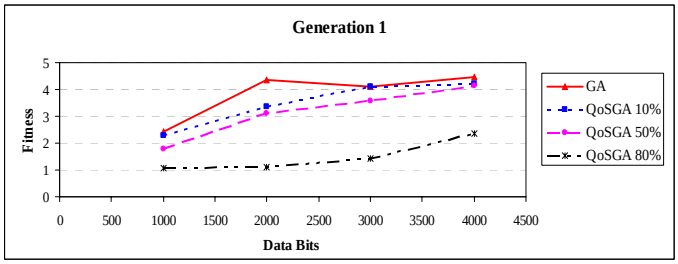

Fig.3: Comparison between original And QGAs at different packet sizes

Table 2
Simulation results in random scenario

Protocol / Metrics	GAs Original	QGAs at 10% performance link	QGAs at 50% performance link	QGAs at 80% performance link
Time period of finding route (sec)	1	1	1	1
Time period for complete transmission (sec)	1.854933	1.64921433	1.79043037	1.15131126

bit error rate and try to find the path having the least number of utilization or low possibility of link failure.

Figure 4 a) and b) reveal some of the chrematistic behaviors of both GAs and QGAs. As expected, the GAs and QGAs converge faster at lesser generation when the population is large. In fact, when the population size is 100, the GAs and QGAs reach a fitness level of 1st generation. For the population size of 50, the same GA also reaches a fitness level of 1st generation.

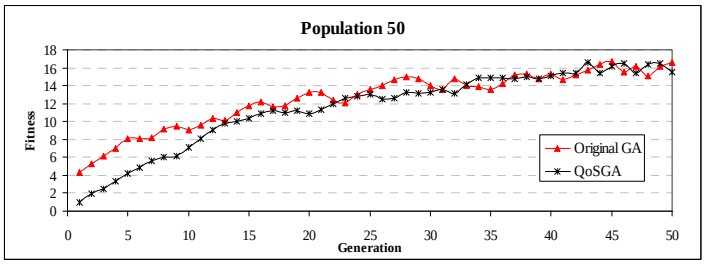
Figure 4 a) and b) show the results of our comparison when the population sizes are enlarged. The capability of QGAs in finding the optimum path for receiving – sending the data packet is better than the original algorithm.

Table 2 confirms that QGAs outperforms for finding the optimum route in wireless mesh network although the time of finding the QGAs route and the original are equal. This is due to the fact that QGAs need some time to search for the best quality route with Link reliability, utilization and chances of errors during transmission in order to reduce time period for re-transmission. From the reason, time period for complete transmission of QGAs is a lot less than that of the original.

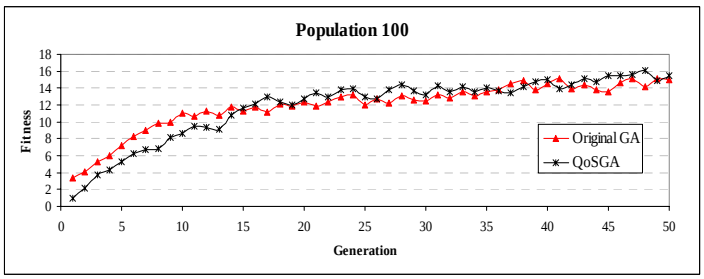
V. Conclusions

In this paper, a new QoS base-on GA scheme is presented to find the optimum route between source and destination node with the consideration of the link quality and quantity.

The simulation results illustrate that QGAs can find the best route with the accurate data transmission compared to the original, although send-receive and network sizes are enlarged. This is because QGAs have a better path finding process based on concerned factors affecting communication. Thus, the time



a)



b)

Fig.4: Comparison of between original And QGAs at different population sizes

period for sending-receiving data is less with high quality of transmission.

***Abstract*- In this paper, we revise the definition of TCP-friendliness for multicast and introduce a new design of Multi-rate Multicast Congestion Control (MR-MCC) by applying a logarithmic receiver dependent policy to the Explicit Rate Adjustment (ERA) protocol. In our design, the receiver explicitly adjusts its reception rate according to the network conditions using Packet-pair Probe. Yet, the TCP-friendliness implementation has been revised in order to give a motivation for multicast deployment. A new multicast TCP-friendly bandwidth allocation scheme is used at any individual router to be multicast-favorable without causing TCP starvation. We have also implemented our MR-MCC design into a network simulator (ns2) and demonstrate via simulations a good performance.**

I. INTRODUCTION

Due to the tremendous growth of the multipart communication applications, such as software distribution, audio/video broadcasting and video conferences, multicast transmission has become significant since it is more bandwidth efficient for one-to-many communication than multiple unicast. However, the congestion control mechanism of multicast has not yet been standardized till now. Multi-Rate Multicast Congestion Control (MR-MCC) has been accepted as a key solution of multicast congestion control for the Internet [7]. Several MR-MCC proposals (such as [10], [4], and [6]) have been made including ours, Explicit Rate Adjustment (ERA) [12, 13].

TCP-friendliness is a main fairness goal for these previous MR-MCC proposals because it is a suggestion from IETF ([9], [1]) for new congestion control protocols running in the best-effort Internet. The purpose of TCP-friendliness is to protect Transmission Control Protocol (TCP) traffic (the majority of Internet traffic) from any new aggressive traffic.

TCP-friendliness definition in [8] demands that a non-TCP flow should receive similar bandwidth shares. In order to be TCP-friendly, previous MR-MCC proposals have been designed to allocate less than or equal bandwidth for a multicast flow in comparison to a TCP flow. However, we argue that the definition of TCP-friendliness for multicast congestion control protocol should be revised. An MR-MCC may serve several receivers, while a TCP flow serves only one. Hence, the MR-MCC flow should deserve more bandwidth than a single TCP (unicast) flow. Giving more bandwidth share would be an incentive to deploy multicast instead of multiple unicast, thus saving network bandwidth. Without this incentive, the overhead of multicast (such as Internet Group Management Protocol (IGMP), complex security issues and difficulties in congestion control) would not be attractive. Most receivers would then prefer to use multiple unicast, and not move to multicast.

Hence, in this paper, we propose to revise the definiton of multicast TCP-friendliness and modify ERA (our previous MR-MCC) by applying a logarithmic receiver dependent bandwidth allocation scheme [5] together with an estimation of an explicit target rate using a *Packet-pair Probe* (PP). The new design provides a multicast congestion control mechanism with responsiveness and a motivation for multicast deployment while not causing TCP bandwidth starvation. Hence, we contribute an innovative MR-MCC framework with a more incentive TCP-friendliness definition. In addition, we have built our design into a network simulator (ns2) and undertaken performance evaluation. The results show a favourable performance.

The remainder of this paper is organized as follows. We begin in Section II by discussion of background and related work. In Section III, we describe the rationale of our new design. The framework and algorithms of new ERA are proposed in Section IV. Section V shows the performance evaluation using network simulation technique. In Section VI, we conclude and discuss the future work.

II. BACKGROUND AND RELATED WORK

A. *Multi-Rate Multicast Congestion Control (MR-MCC)*

MR-MCC is based on the ability of a source to generate the same data at different rates over multiple multicast streams (using Layer Coding Transport (LCT) [7]). The multiple multicast groups are organized into logical layers. Each layer is each multicast group. The burden of congestion control is at the receiver's side. The source has only a passive role, so this approach is called receiver-driven. A receiver tunes its reception rate by subscribing to and unsubscribing from layers according to its network condition. Different receivers may subscribe at different levels of their own subscription rates, especially when they are in different network conditions

Receiver-driven Layered Multicast (RLM) [10] is the first proposal of MR-MCC. Packet-pair Layered Multicast (PLM) [4], Wave and Equation Based Rate control (WEBRC) [6] and ERA [12] are some previous proposals of MR-MCC.

[1] A postgraduate student at Khon Kaen University, Thailand

B. *TCP-friendliness*

More than 90% of today's Internet traffic is TCP-based. To protect the majority population from aggressive traffic, the Internet community [1] suggests that new congestion control mechanisms for traffic likely to compete with best-effort TCP traffic should be TCP-friendly. TCP-friendliness (also known as TCP compatibility) is actually the inter-protocol fairness towards TCP. The TCP-friendliness definition [8] demands that a TCP flow and a non-TCP flow should receive similar steady-state bandwidth shares, if they traverse the same path and thus face similar round trip delays and packet loss rates. Previous MR-MCC protocols have been designed to provide TCP-friendliness in such a strict manner by allowing the multicast flow to use less than or equal bandwidth share to TCP.

C. *Fairness Paradigm Between Multicast and Unicast*

As mentioned previously, a multicast flow may serve more than one receiver, while a unicast flow only serves one. If we want to give a motivation to use multicast instead of multiple unicast, the fairness definition between multicast and unicast must given the multicast flow a favor. There have been a few initial studies focusing on defining a better fairness paradigm between multicast and unicast. For example, Wang et al. have defined *Bounded Fairness* or *Essential Fairness* (against the current paradigm, Absolute Fairness), as the situation in which bandwidth allocated for multicast may not be the same as bandwidth allocated for unicast. The multicast flow in this sense of fairness may be allocated more bandwidth than TCP at a certain boundary. Furthermore, Legout et al. [5] proposed that the bandwidth allocation for multicast should consider the number of downstream receivers. They demonstrated three possible schemes of bandwidth allocation, namely Receiver Independence (RI), Linearly Receiver Dependence (LinRD) and Logarithmically Receiver Dependence (LogRD). They have also shown that LogRD is the best among three.

III. RATIONALES OF THE NEW DESIGN

Two main goals of MR-MCC design are responsiveness and TCP-friendliness. ERA was one of the successful MR-MCC design, proposed by Puangpronpitag et al. in [12, 13]. It is equipped with the "explicit receiving rate adaptation" using Packet-bunch Probe and TCP-friendly algorithm to provide responsiveness and TCP-friendliness. Like other previous MR-MCC designs, ERA uses a TCP-friendliness as a fairness paradigm. So, ERA will not use the bandwidth more than TCP even in the situation that an ERA flow may serve many more receivers than a TCP flow.

Hence, we revise the definition of TCP-friendliness for multicast and interpret it in a more relaxing way by allocating more bandwidth to the multicast flow correspondent to the number of its downstream receivers. We still believe in the key idea of TCP-friendliness to protect TCP from bandwidth starvation due to aggressive traffic. So, we apply LogRD bandwidth allocation policy at every router instead of the strict TCP-friendly rate. LogRD policy has been proven to provide more bandwidth allocated to multicast without starving TCP [5]. While this implementation should be more attractive for multicast deployment, it is still TCP-friendly in a way of not aggressive towards TCP.

To provide responsiveness, we still keep the "explicit receiving rate adaptation" using Packet-bunch Probe at the receiver operation. Moreover, LCT at source operation is also kept.

IV. FRAMEWORK AND ALGORITHMS

Multicast Support at network layer: Our design assumes IP multicast at the network layer. We also assume that there is a mechanism (such as, [3], [2]) to indicate the number of downstream receivers of the multicast flow at every router.

Network-assisted congestion control: Our design proposes LogRD bandwidth allocation policy to be implemented at each router.

Layered coding and receiver-driven: Our design uses a receiver-driven layered multicast approach to provide scalability for a very large heterogeneous group of receivers.

Explicit rate adjustment: We believe that finding a simple mechanism for explicit rate adjustment would simplify the congestion control problem. According to our algorithms, the receiver adjusts its reception rate to the target rate, which is explicitly calculated as the estimated available bandwidth. The details was described in [12]).

Receiver Coordination: The coordination of the receivers under the same bottleneck link is necessary to obtain intra-session fairness. In addition, this co-ordination is significant to utilize bandwidth efficiently and handle congestion properly. ERA provides the coordination by relying on *Session Announcement Message (SAM)* and *Rate Adaptation Interval (RAI)* as follows. The source sends a *SAM* at predefined times to provide information about the transmission session. *RAI* is a part of the information provided in *SAM*. The receiver can join a transmission session only after it has received a *SAM* and will adapt its reception rate every *RAI*.

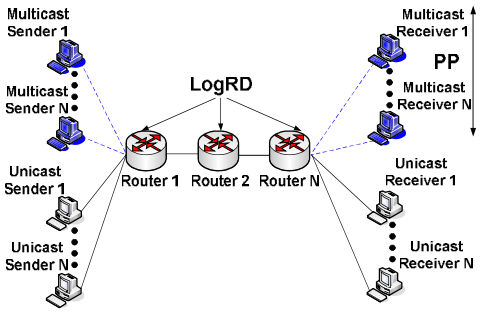

Figure 1 Modification of ERA design

Figure 1 shows the new of ERA design consisting of LogRD mechanism at the routers and Packet-bunch Probe (PP) at the receivers. The main part of ERA algorithms provided in [12]) are still same except the followings:

(1) We apply LogRD as the bandwidth allocation mechanism at each router as shown in Figure 2.

(2) The TCP-friendly rate in the old ERA's design is not used as a boundary of reception rate anymore. Yet, the LogRD bandwidth allocation (in (1)) will protect TCP from starvation while provide more bandwidth to multicast according to the number of its downstream receivers. The reception rate adaptation mechanism has been revised as follows:

LogRD algorithm at the router

Procedure LogRD (C, k, m, type) {

If type = 'UNICAST' **Then**

Return $\sum_{i=1}^{k} \frac{1}{k+(1+\ln m)} C$

Else If type = 'MULTICAST' **Then**

Return $\sum_{i=1}^{m} \frac{(1+\ln m)}{k+(1+\ln m)} C$

End If

}

when C = the available bandwidth,
k = the number of unicast flow
m= the number of multicast flow

Figure 2 LogRD algorithm

For every arrival of packet-pair, the receiver estimates the available bandwidth (R'_{pp}) using the technique mentioned in [12]. If the subscribed rate is higher than R'_{pp}, the receiver will immediately adapt its reception rate down to avoid overloading the network.

For every *Rate Adaptation Interval (RAI)*, the receiver calculates an estimated bandwidth R_{pp} as the minimum R'_{pp} during the last *RAI*. There may be a pathological case, when packet pairs are lost during severe congestion. Then, we may not have enough R'_{pp} to make a good estimation of available bandwidth (R_{pp}). In this case, we set R_{pp} to –1 to indicate severe congestion.

The receiver calculates its current subscribed rate (R_i) with respect to the number of subscribed layers (i) maintained at the receiver, and a data rate of each layer obtained from the session description.

1. The receiver then set the target reception rate (R_{TARGET}) as R_{pp}. If R_{pp}=-1, the receiver unsubscribes one layer to solve the severe congestion.
2. The receiver subscribes to or unsubscribes from layers according to the R_{TARGET} as follows:

```
If (Ri > RTARGET) Then
  Repeat Until (Ri ≤ RTARGET)
    If i > 0 Then
      Unsubscribe from a layer
      i = i -1
    Else
      EXIT the session
    End If
  Loop

Else If (Ri < RTARGET)
  Do While (Ri+1 < RTARGET)
    Subscribe to a layer
    i = i +1
  Loop
Else If (Ri = RTARGET)
  Maintain the current subscription level
End If
```

V. PERFORMANCE EVALUATION

A. Simulation Tools

We have integrated our algorithms into the ns2 network simulator [11] and conducted a performance evaluation to test our protocol extensively. Each simulation is run 20 times using a different Random Number Generator parameter. Results are averaged and quoted with respect to confidence intervals of 95%.Due to space limitation, some key simulation experiments are only sampled and summarized.

B. Simulation Scenarios & Parameters

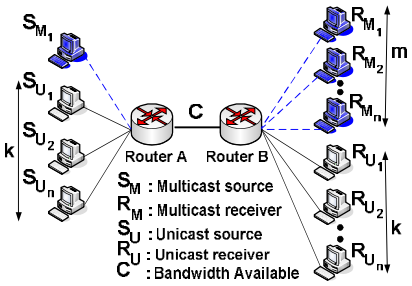

Figure 3 Simulation topologies

As shown in Figure 3, the topology used in our experiments is the dumbbell topology, having 1 multicast sender and k unicast (TCP) senders at one end and m multicast receivers and k unicast receivers at the other end as well as the bottleneck link at the middle. We randomly start the TCP source after 10 seconds and then start multicast source after 30 seconds to observe the responsiveness of the congestion control mechanism. We are interested in bandwidth allocation between TCP and multicast after increasing the number of multicast downstream receivers.

C. Experiment I : one downstream receiver

In this experiment, we use a multicast flow with one downstream receiver competing with a TCP flow. Figure 4 show the TCP-friendliness of our new ERA. So, LogRD at router can replace the function of TCP-friendly rate of the old design very well in case of one downstream receiver.

D. Experiment II: many downstream receivers

In this experiment, we use a multicast flow with several downstream receivers competing with a TCP flow. Figure 4 shows the results in case of 2 downstream receivers of multicast. From the figure, the multicast flow gains more bandwidth than the TCP flow. However, it does not starve the TCP connection. We have also run further experiments by increasing the number of multicast downstream receivers to 10 and 100 and still find that the new ERA mechanism does not starve the TCP connection. Moreover, the new ERA gains more bandwidth than TCP since it serves more receivers. This would inspire people to deploy multicast instead of multiple unicast that consumes more bandwidth.

In order to understand more about LogRD bandwidth allocation, we assume 400 Kbps of bandwidth and a multicast flow competing with a TCP flow. By increasing the number of

multicast downstream receivers, we calculate the bandwidth allocation between the multicast and TCP according to the algorithm described in Section IV. The results are shown in Table 1. From the results, it is clear that the logarithmic receiver dependent policy can give incentive to multicast deployment and does not starve the TCP connection even at 10,000 downstream receivers.

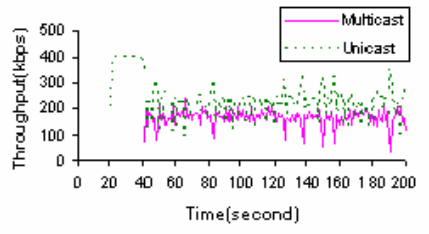

Figure 4 Experimental result I

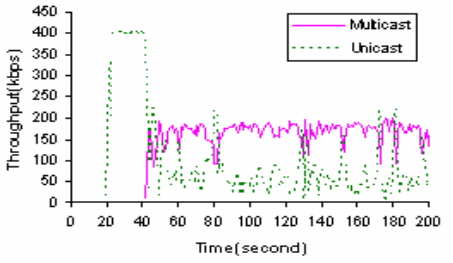

Figure 5 Experimental result II

Table 1 LogRD bandwidth allocation according to the number of multicast downstream receivers

# receivers	Multicast		TCP	
	Kbps	%	Kbps	%
1	200.00	50.00%	200.00	50.00%
2	251.47	62.87%	148.53	37.13%
3	270.91	67.73%	129.09	32.27%
4	281.88	70.47%	118.12	29.53%
5	289.18	72.29%	110.82	27.71%
6	294.51	73.63%	105.49	26.37%
7	298.63	74.66%	101.37	25.34%
8	301.95	75.49%	98.05	24.51%
9	304.70	76.17%	95.30	23.83%
10	307.03	76.76%	92.97	23.24%
100	339.44	84.86%	60.56	15.14%
1000	355.10	88.77%	44.90	11.23%
10000	364.32	91.08%	35.68	8.92%

One may argue that the TCP flow gains less bandwidth allocation. Yet, the reason is quite clear that the multicast flow must gain more bandwidth due to serving more receivers. If there is no incentive to use multicast as we proposed. The multiple unicast would be used instead. The network loads are then increased. Furthermore, in that case, the situation of the TCP flow will be even worse. For example, at 10 multicast receivers, from Table 1, we gain 307.03 Kbps for 1 multicast flow and 92.97 Kbps for 1 TCP flow. If the multicast flow is replaced with multiple unicast flows, there will be 11 unicast flows sharing 400 Kbps bandwidth. The TCP flow would gain only 36.36 Kbps instead (if the 11 unicast flows allocate bandwidth fairly). So, it would be far better to give some more bandwidth to the multicast flow when it serves more receivers.

VI. Conclusions and Future Work

Due to the strict definition of multicast TCP-friendliness, there has been no incentive to use MR-MCC. So, we have revised the definition of TCP-friendliness for MR-MCC that it should gain more bandwidth than TCP corresponding to its number of downstream receivers. Yet, MR-MCC should not starve TCP. To follow this new MR-MCC TCP-friendliness definition, our previous MR-MCC protocol (ERA) has been redesigned by changing the rate adaptation algorithm and applying a logarithmic receiver dependent policy at each router. After implementing and simulating by ns-2, the initial experimental results demonstrate that TCP is not starved due to our new protocol. Yet, our new protocol can be more attractive to be deployed as gaining more bandwidth. In the future, we plan to further experiment on our protocol to evaluate the performance extensively.

***Abstract*- In this paper, the simple structure of slot antenna fed by coplanar waveguide (CPW) is considered for dual frequency. For increasing the antenna bandwidth, the conductor stub is proposed by overstep the central conductor (signal strip) into slot antenna. By sufficient choosing shape and size of conductor stub, can be achieved the wide bandwidth 23.8% (2.22-2.82 GHz) and 86.04% (3.88-9.74 GHz), which can use in WLAN applications coverage standard of IEEE 802.11b/g (2.4-2.4835 GHz), IEEE 802.11j (4.90-5.091), IEEE 802.11a (5.15-5.35 GHz), IEEE 802.16d (5.7-5.9 GHz). The simulation results of this slot antenna are analyzed by using MoM from IE3D Software [1].**

I. INTRODUCTION

Coplanar waveguide (CPW) transmission line has increased significantly in recent years. The antennas fed by CPW have several useful properties. The properties include wider bandwidth, better impedance matching, and lower radiation losses. Also slot antennas have wider impedance bandwidth as compared to microstrip patch antennas [2]. The advantages of CPW fed slot antenna is wideband antenna which many research introduced the several shape of slot antenna for use in Wireless Local Area Network (WLAN) communications systems [3]. However, conventional the CPW fed slot antennas is not large enough bandwidth to cover the demand of Wireless LAN communications systems.

In this paper presents a CPW fed slot antenna for dual frequency of WLAN application at low frequency band 2.4 GHz and high frequency band over 4 GHz. We will begins considering the simplest and most basic configuration of CPW-fed slot antenna. Finally, we will try to maximize bandwidth by using conductor stub to keep the return loss to minimum. The simulation results of bandwidth at low frequency 2.4 GHz is 23.8% and at high frequency over 4 GHz is 86.04%

II. ANTENNA DESIGN

In this paper, IE3D software package of Zeland [2] is used to design and simulation. This antenna is designed on dielectric constant ε_r = 2.2 and a thickness h = 1.575 mm at design frequency 2.4 GHz.

In this case, the parameters of slot antenna structure are as following:

Width of antenna, W_a = 72 mm
Length of antenna, L_a = 47 mm
Width of CPW feed line, S_f = 0.3 mm
Width of signal strip, W_f = 3.0 mm
Length of CPW feed line, L_f = 25 mm

In the design of CPW-fed slot antenna, we will begins to consider the simplest basic configuration and developing for wide band by using conductor tuning stub for maximize bandwidth.

A. Design Antenna on Simple Configuration

Figure 1 (a) shown the simple structure of CPW fed slot antenna at design frequency 2.4 GHz. For match impedance with 50 ohms transmission line, the CPW feed line has a signal strip W_f = 3.0 mm, a gap width S_f = 0.3 mm, and length of CPW feed line L_f = 25 mm ($\approx \lambda_g/4$). The length of slot antenna (L_a) depends on guide wavelength λ_g, which is approximately the half of the guided wavelength ($\approx \lambda_g/2$) at frequency 2.4 GHz. The length of slot antenna is given by

$$\lambda_g = \frac{\lambda_0}{\sqrt{\varepsilon_{eff}}} \tag{1}$$

$$\varepsilon_{eff} \approx \frac{\varepsilon_r + 1}{2} \tag{2}$$

$$Z = \frac{30\pi}{\sqrt{\varepsilon_{eff}}} \cdot \frac{K'(k_1)}{K(k_1)} \tag{3}$$

$$k_1 = \frac{w_f}{w_f + 2s_f} \tag{4}$$

$$k' = \sqrt{1-k^2} \tag{5}$$

$$\frac{K(k)}{K'(k)} = \frac{\pi}{\ln\left[2\frac{1+\sqrt{k'}}{1-\sqrt{k'}}\right]} \quad \text{for } 0 \le k \le \frac{1}{\sqrt{2}} \qquad (6)$$

$$\frac{K(k)}{K'(k)} = \frac{\ln\left[2\frac{1+\sqrt{k}}{1-\sqrt{k}}\right]}{\pi} \quad \text{for } \frac{1}{\sqrt{2}} \le k \le 1 \qquad (7)$$

where λ_0 is the free space wavelength at 2.4 GHz.

λ_g is the guided wavelength at 2.4 GHz.

ε_{eff} is an effective dielectric constant.

Z is the impedance.

.

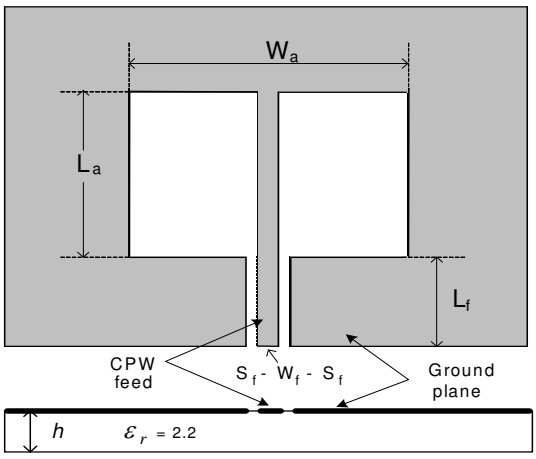
In this case, the λ_0, λ_g, and L_a are 125mm, 98.82 mm and 47 mm, respectively.

B. Design Antenna with Stub Tuning

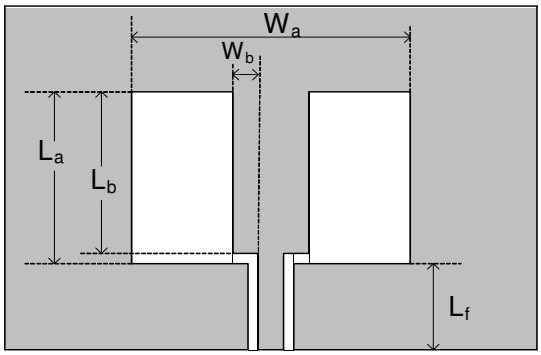
The stub tuning is proposed for maximize wide bandwidth, as shown in Figure 1(b) and 1(c). The procedure to increasing bandwidth of some frequency-band is:

1. Expanding the central conductor (strip signal) by overstepping into both side of slot antenna, Figure 1(b).
2. Next from case I, to overstepping the small conductor as shown in Figure 1 (c).

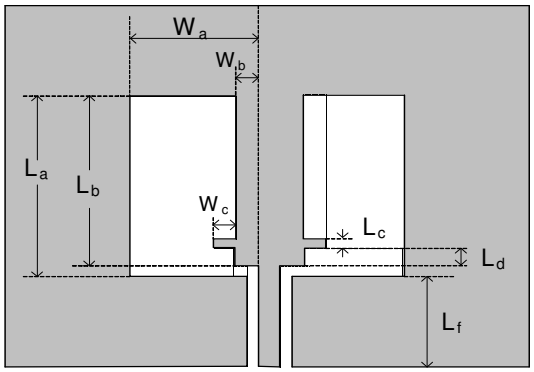
The parameters of conductor stub in Figure 1(b) are W_b and L_b which are adjusted for good matching. While Figure 1(c) adding three parameters of conductor stub, W_c, L_c, and L_d. Reasonable to maximize bandwidth, the value of W_b and L_b in case of minimum return loss is chosen. Finally, the W_c, L_c, and L_d is adjusted for wideband at high frequency.



(a)



(b)



(c)

Figure 1. Configuration of the CPW fed slot antenna. (a) basic structure (b) with tuning L_b and W_b (c) with tuning L_c, W_c and L_d.

III. RESULTS

Figure 2 shown the simulation result of return loss (S_{11}) in varying value of W_a to 47, 72 and 80 mm by fixing L_a to 47 mm which the structure of antenna as shown in Figure 1(a).

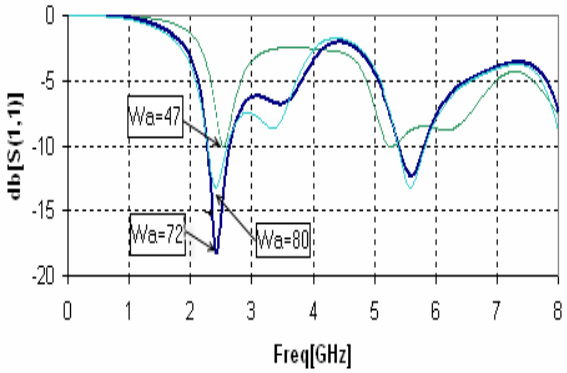


Figure 2. Simulation results of return loss by adjust W_a.

The best value of W_a for good matching is 72 mm. Thus, we will fix the value of L_a and W_a to 47 mm and 72 mm, respectively. In this case, the simulation results are shown in Table I.

TABLE I

Simulation results of Figure 1 (a) by fixed L_a = 47 mm.

W_a (mm)		47	72	80
Lower Frequency	Resonance Freq (GHz)	2.54	2.42	2.42
	Return Loss (dB)	-10.07	-18.33	-13.18
	BW (%)	0.79	13.38	12.34
Higher Frequency	Resonance Freq (GHz)	5.28	5.60	5.58
	Return Loss (dB)	-10.08	-12.31	-13.17
	BW (%)	1.51	6.77	7.48

From Figure 1(b), the central conductor is overstepped into slot antenna. The analytical affect of adjusting W_b and L_b will be considered, first analysis by fixed W_b to 8.5 mm and adjust L_b, and next choose L_b from first analysis base on return loss (S_{11}) and fixed it then adjust W_b. The simulation of return loss and bandwidth are shown in Figure 3-4 and Table 2-3, respectively.

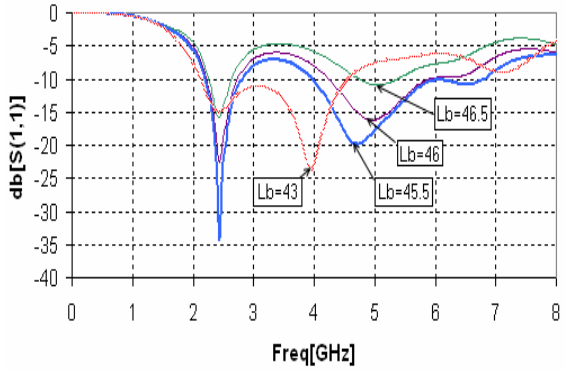

Figure 3. Simulation results of return loss by adjust L_b.

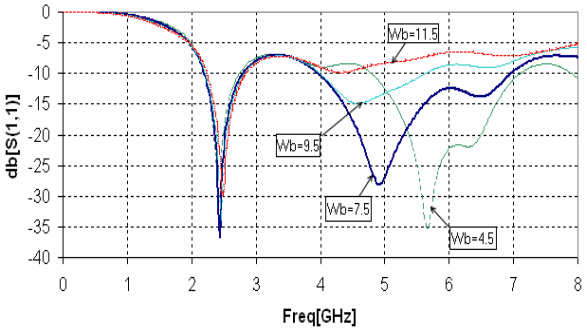

Figure 4. Simulation results of return loss by adjust W_b.

TABLE II

Simulation results of Figure 1(b), L_a=47 mm , W_a=72 mm, W_b= 8.5 mm.

L_b (mm)		43	45.5	46	46.5
Lower Frequency	Resonance Freq (GHz)	2.42	2.44	2.44	2.42
	Return Loss (dB)	-15.03	-34.35	-22.52	-15.76
	BW (%)	72.67	23.10	19.35	13.87
Higher Frequency	Resonance Freq (GHz)	3.94	4.7	4.94	5.04
	Return Loss (dB)	-23.72	-19.91	-16.18	-10.89
	BW (%)	-	52.31	32.74	12.22

TABLE III

Simulation results of Figure 1 (b): L_a=47 mm , W_a=72 mm, L_b = 45.5 mm.

W_b (mm)		4.5	7.5	9.5	11.5
Lower Frequency	Resonance Freq (GHz)	2.42	2.44	2.46	2.48
	Return Loss (dB)	-32.36	-36.79	-33.82	-30
	BW (%)	21.86	23.29	23.10	22.92
Higher Frequency	Resonance Freq (GHz)	5.66	4.92	4.6	-
	Return Loss (dB)	-35.28	-28.29	-14.93	-
	BW (%)	38.65	54.21	33.67	-

Figure 3 shown the low resonance frequency is slightly changed and high resonance frequency shift up when value of L_b is increased. Comparing between S_{11} for each value of L_b, we will choose L_b = 45.5 mm and use this value to find out W_b for better matching and wideband.

Figure 4 shown low resonance frequency is changed same as Figure 3, while high resonance frequency shift down when value of W_b is increased. In this case, the good matching can be achieved when L_b = 45.5 mm and W_b = 7.5 mm which are used to analyze for maximized bandwidth in next step.

Finally, we overstep the small conductor into slot antenna by adjust three parameters: L_c, W_c, and L_d, as shown in Figure 1(c). By sufficient choosing value of L_c = 1 mm, W_c = 5 mm and L_d= 6 mm, the simulation result of S_{11} is shown in Figure 5. In this case, we achieved the wide bandwidth at high frequency from 3.88 – 9.74 GHz (5.86 GHz or 86.04% of the center frequency 6.81 GHz) and at lower frequency from 2.22 - 2.82 GHz (0.6 GHz or 23.8%).

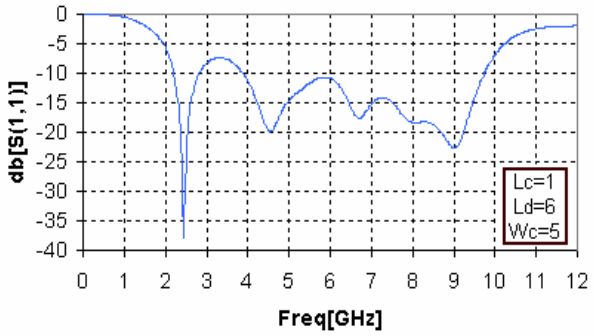

Figure 5. Simulation results of return loss by adjust L_c, W_c and L_d.

TABLE IV

Simulation results of Figure 5.

L_a = 47 mm, W_a = 72 mm, L_b = 45.5 mm, W_b = 7.5 mm, L_c = 1 mm, W_c = 5 mm, and L_d = 6 mm					
Lower Frequency			Higher Frequency		
S_{11} (dB)	Bandwidth (GHz)	Gain (dB)	S11 (dB)	Bandwidth (GHz)	Gain (dB)
-37.96	0.6	3.59	-22.69	5.86	4.43

Table IV shown the characteristic of return loss, gain and bandwidth of this slot antenna.

The radiation pattern gain xy-plane and xz-plane are shown in Figure 6-9. The antenna is obtained on center band of low frequency at 2.52 GHz and of high frequency at 6.8 GHz.

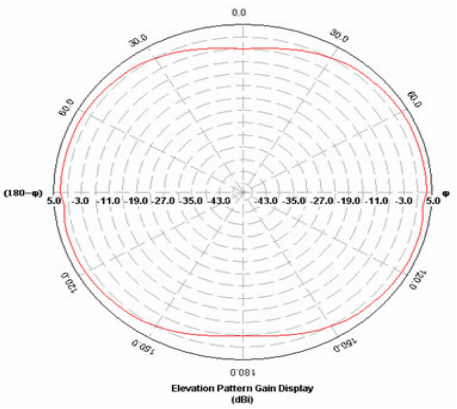

Figure 6. XZ plane at f = 2.52 GHz.

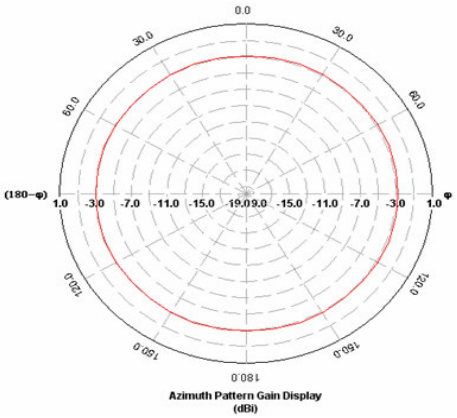

Figure 7. XY plane at f = 2.52 GHz.

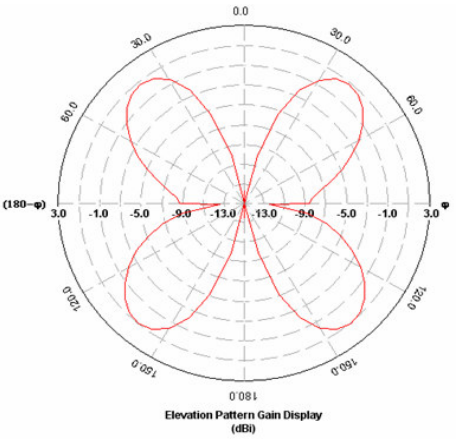

Figure 8. XZ plane at f = 6.8 GHz.

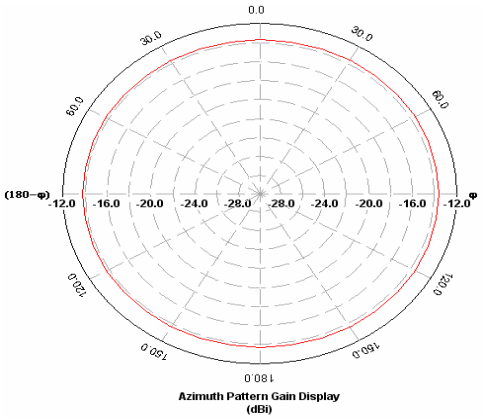

Figure 9. XY plane at f = 6.8 GHz.

IV. CONCLUSION

The slot antenna fed by CPW is designed for dual frequency 2.4 and 5 GHz bands. The stub tuning technique is proposed for wide-band which has two step tuning. By sufficient choosing size of conductor stub, can be achieved the wide bandwidth of 23.8% (2.22-2.82 GHz) and 86.04% (3.88-9.74 GHz), which can use in WLAN applications and communication system. The frequency bandwidth of the proposed slot antenna for dual frequency is large enough to coverage standard of WLAN communications systems.

***Abstract*-This paper presents the compact and wideband U-shaped cross-sectional antenna on a U-shaped ground plane for WLAN system. The antenna prototype is fabricated for testing after the geometry is analyzed by using the FDTD method. The antenna element is contributed from a piece of rectangular thin metal-sheet which is folded to form a U-shaped, then, the bottom is etched to form a cross-strip at the center by two wide-slots, respectively. It is cross-placed on the U-shaped ground plane which is folded as its element. The antenna has overall dimension of 110 x 84 x 33 mm^3 with an impedance bandwidth (2:1 VSWR) of 40%, an average gain of 8.5 dBi., front-to-back ratio and cross-polarization level in both E-and H-plane greater than 20 dB across the bandwidth, and half power beam-width in both E- and H-plane of 80º at 2.45 GHz. The proposed antenna is suitable for implementing as an access point of the WLAN under the IEEE802.11 b, g standard.**

I. INTRODUCTION

Wireless communication systems are continuously developed in both transmitting and receiving the image, voice, and data. Especially for the wireless internet, it is growing very fast as we can see from the extending of the internet service providers (ISPs). Presently, wireless networks are used in everywhere with the name of WLAN (Wireless Local Area Network), since it is convenient to install without wiring a line for connecting [1]. The problem of drilling floor/wall is also negligible. However, the system must be under the IEEE 802.11b, g standard which operated in the ISM band or the frequency range of 2.4 - 2.484 GHz. Thus, antennas for this operating are the important equipment.

Compact antennas are required because the users need to suppress access points for the installation with the causes of the great point of view, light weigh, and easily to install. In order to decrease the antenna size, it can be treated to the ground plane. For this, it directly effects to the antenna performance especially for gain and front-to-back ratio. However, the technique for treating the ground plane with enhancing the antenna performance has been proposed in [2] but it is not the decreasing of the antenna size. The useful technique for decreasing the antenna size has been proposed in [3].

This paper describes the decreasing of the antenna size for using in WLAN operation that has not been proposed before as the geometry like this. The antenna develops from the U-shaped cross-sectional antenna on a U-shaped ground plane. The advantage is not only for it is a compact structure, it also provides a wide bandwidth in addition. The wideband antenna is more flexible than the narrowband antenna because when they are fabricated, it is not seriously to tune the operating frequency makes it easily to produce in the industrial part. For this reason, the material is also easily to find in the local market and not necessary to use an expensive substrate makes the antenna is low cost as well. The antenna was designed to have a mid-band at 2.45 GHz or closed to the central operating frequency of the WLAN. The analysis of the antenna was conducted by using the Finite-difference Time-domain (FDTD) method.

II. ANTENNA DESCRIPTIONS

For the antenna structure, it is the U-shaped cross-sectional antenna on a U-shaped ground plane as shown in Figure 1 [3]. The antenna element is contributed from a piece of rectangular brass sheet that has the thickness of 0.4 mm and is folded to form a U-shaped. The dimension have the length of a = 50 mm, the width of b = 52 mm, and the height of d = 30 mm. Then, the bottom is etched to form a cross-strip at the center by two wide-slots. The cross-strip have the width of w_1 = 10 mm, free-end-strip width of w_2 = 10 mm and the length of s = 14 mm, and the connected-strips width of t = 4 mm. The free-end-strip of the cross-strip is far from its front side connected-strip of l = 26 mm. The antenna element is cross-placed with the 1 mm thickness aluminium ground plane which is folded to form a U-shaped as its element with the size of 110 x 84 x 33 mm (G_x x G_y x G_z) for the length, the width, and the height,

respectively. They are separated by space with the thickness of h = 3 mm or the layer which has the dielectric constant close to unity. The antenna is fed by a probe pass-through a transmission line in the sequence at the center of the dimension a on the front side. The transmission line have the width of w_1 = 10 mm and the length of f = 14 mm while the probe is through-holed by the 50Ω SMA connector with the length of 2 mm. All dimensions are indicated as show in TABLE I.

Prototype of the U-shaped cross-sectional antenna on a U-shaped ground plane is fabricated with the dimensions and the materials as indicated above for comparison and to confirm the accuracy of the simulation. The antenna element is supported by foam beneath for the air layer.

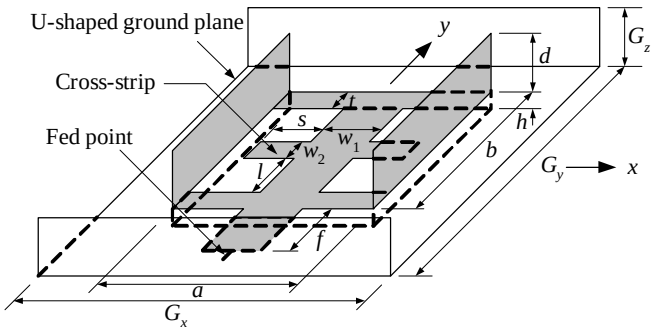

Figure 1. Structure of the U-shaped cross-sectional antenna on a U-shaped ground plane.

TABLE I
DIMENSIONS OF THE PROPOSED ANTENNA

Parameters	Dimensions (mm)
a	50
b	52
d	30
h	3
w_1	10
w_2	10
s	14
l	26
t	4
f	14
G_x	110
G_y	84
G_z	33
thickness (brass sheet)	0.4
thickness (ground-plane)	1

The analysis is carried out by the Finite-Difference Time-Domain method. This method is applied because it is simple to understand, capability, and flexibility. The detail of the FDTD theory can be found in [4] – [6]. For the simulation, a simple fed gap model is used, in which a voltage is introduced in one cell of the coaxial over a conducted plane. The return loss is obtained from the input impedance which is the ratio of the Fourier transform of the input voltage and the input current. The chosen PML is 8 grids. The virtual surfaces for the calculating of the radiation pattern are 10 grids from the outer boundary in all directions and 20 grids for the edges of the antenna components. The time step is 0.441 ps while the Gaussian half-width is 15 ps and the time delay is set to be 3 times of the Gaussian half-width. With the FDTD method, both the fed probe and the conducted material are assumed to be very thin.

The dimensions of the antenna were optimized by the simulation of the FDTD method as presented in [3]. Therefore, a and b are chosen under the assumption that they are about half of wavelength (λ_0). The width of w_1 and w_2 is defined to be nearly the 50Ω microstrip-line and the 100Ω for t which corresponded to the substrate layer height of h of the mid-band frequency (2.45 GHz). From the study, we found that the dimension of d is approximately $0.25\lambda_0$ and the width of the ground plane in the x-direction (G_x) is less sensitive to the input impedance thus it is fixed at 110 mm or $0.9\lambda_0$ in size for the good front-to-back ratio of ~20 dB and gain of ~8.5 dBi. G_z is assigned to equal with the appropriate height of d as described in [3]. Amount of s and l are used to tune the impedance matching and decreasing the cross-polarization level. To simplify the analysis, s is fixed at 14 mm while l, f, and G_y are varied for decreasing the antenna size.

III. SIMULATED AND MEASURED RESULTS

The first parameter to vary is G_y which is used for indicating the antenna size. When G_y is varied, all parameters are fixed as TABLE I except f that is also directly varied with G_y in the ratio of $\Delta G_y/2$ where ΔG_y is the differenced changing of G_y.

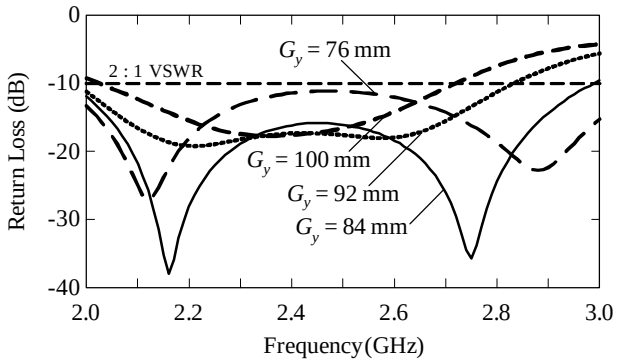

Figure 2. Simulated return losses of difference G_y.

Figure 2 shows the simulation results of the return loss of difference G_y. It is found that, G_y is mainly sensitive to the low and high frequency of the bandwidth (VSWR < 2 : 1) and slightly sensitive at the operating frequency of 2.45 GHz when G_y is decreased from 100 mm to 92 mm and to 84 mm. The impedance bandwidth is extended while the impedance matching is not change at 2.45 GHz but is greater at the low

and high frequency of the bandwidth. The resonant frequencies are clear to observe where the low resonant frequency is from the U-shaped cross-sectional antenna element and the high resonant frequency is from the U-shaped ground plane. When G_y is decreased to 76 mm, the impedance bandwidth is continuously extended but the impedance matching is become decrease. Notice that for the proposed antenna geometry with the operating frequency of 2.45 GHz, the proper size is about 110 x 84 x 33 mm^3.

The other parameter to be varied is *l*. As the varying of G_y, all dimensions are fixed as shown in TABLE I and *l* is changed between the length of 18 mm, 22 mm, and 26 mm. The simulation results of the return loss are shown in Figure 3. When *l* is increased from 18 mm to 22 mm and to 26 mm, the impedance bandwidth tends to narrow while the impedance bandwidth is better. Notice that the length of *l* can be used to tune the impedance matching. However, since the geometry of the antenna, *l* is bounded with the connected-strips.

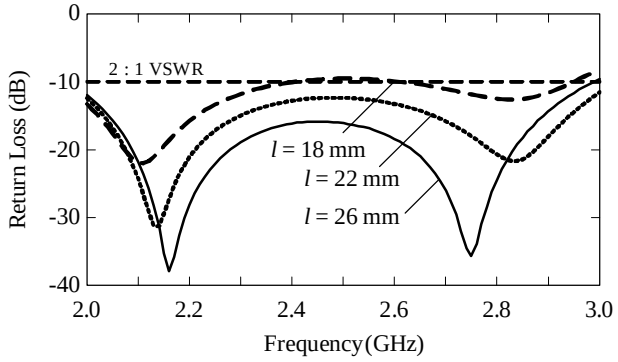

Figure 3. Simulated return losses of difference *l*.

After analysis, the appropriate parameters are chosen as in TABLE I. The simulated result of the return loss is agrees with the measured result as shown in Figure 4. The return loss of the fabricated antenna was measured using an HP 8510C Network Analyzer (50 MHz - 40 GHz) in anechoic chamber. Both simulated and measured return losses of the U-shaped cross-sectional antenna on a U-shaped ground plane provide the bandwidths of about 40% (VSWR < 2 : 1) at 2.45 GHz between the frequency range of 2.0 GHz to 3.0 GHz. Anyhow, the range of measured bandwidth is slightly narrower than the simulated one. The discrepancy is mainly due to the thickness of the constructed material of the antenna which is assumed to be very thin in the FDTD simulation but not in the practice.

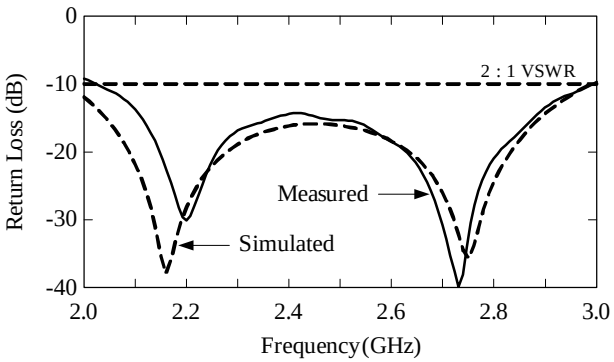

Figure 4. Measured return losses of the U-shaped cross-sectional antenna on a U-shaped ground plane.

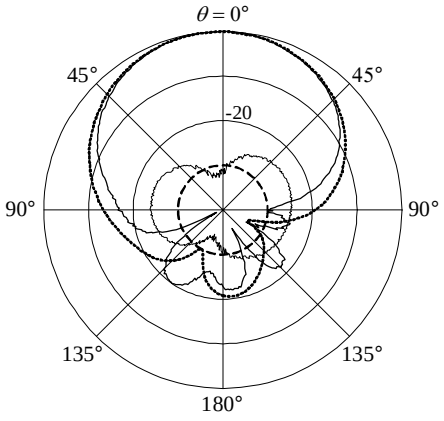
The simulated far-field radiation patterns are computed by FDTD method while the measured radiation patterns are experimented in the anechoic chamber by using an HP8530A antenna measurement system at the operating frequency of 2.45 GHz

Figure 5(a) shows the simulated E-plane co- and cross-polarization patterns compared with the measured ones while Figure 5(b) are the results of H-plane. It is found that the front-to-back ratio is about 20 dB. The half power beam-width (HPBW) on the E-plane pattern is ~82° which is slightly difference from the H-plane pattern, which has the HPBW of ~80°. Moreover, the H-plane co-polarization pattern is more symmetry than the E-plane because of the antenna geometry and the position of the fed point. For HPBW, we can adjust by varying the dimensions of *a*, *b*, G_x, or G_y.

For the radiation patterns in Figure 5(a), the simulated E-plane cross-polarization is not show because it is very low when compared with the co-polarization.



(a)

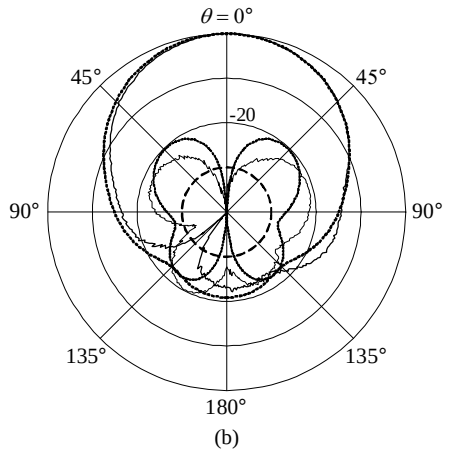


Figure 5. Measured co-polarization radiation patterns of the U-shaped cross-sectional antenna on a U-shaped ground plane at the frequency of 2.45 GHz (a) E-plane (b) H-plane

Figure 6 shows the measured antenna gains of the U-shaped cross-sectional antenna on a U-shaped ground plane across the bandwidth. Gain is high in the range of bandwidth and it is rapidly decrease out of the frequency range. The average gain is about 8.5 dBi.

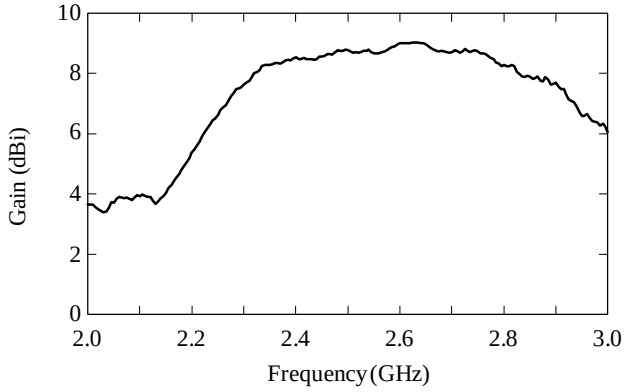

Figure 6. Antenna gain of the U-shaped cross-sectional antenna on a U-shaped ground plane between the frequency range of 2.0 - 3.0 GHz

IV. CONCLUSION

This paper presents the applying of the U-shaped cross-sectional antenna on a U-shaped ground plane with the WLAN. From the measurement, we found that the antenna has the HPBW in both E- and H-plane of ~80° and front-to-back ratio of >20 dB at the frequency of 2.45 GHz. The average gain is ~8.5 dBi. The measured return loss has a bandwidth of ~40% (2.0 GHz – 3.0 GHz). Advantages of this antenna are compact and wideband lead to benefit in constructing. The antenna is very suitable for implementing as a access point in the WLAN communication system.

***Abstract*-This paper presents an array antenna using the technique of fractal geometry. The antenna is designed to operate at the frequency 2.45 GHz, which is used in the application of wireless LAN. A single fractal antenna is created by iterating an Narrow Pulse (NP) generator model at each side of normal square patch antenna. The advantage of fractal technique is that can reduce the antenna size compared with normal square patch antenna. The array elements are equally space between edges of each element, which equally space is 0.05 λ_g. It found that the size of antenna can be reduced and the side lobe of the radiation pattern can also reduce compared with the array of normal square patch antenna. However, the radiation patterns of the proposed antenna are still identically to the normal square patch antenna array. The properties of the antenna such as return losses, radiation patterns and gain have been carried out via numerical simulation and measurement.**

I. INTRODUCTION

Nowadays, wireless communication systems are becoming increasingly popular. There have been ever growing demands for antenna designs that possess the following highly desirable attributes: compact size, low profile, multi-band, and etc. There are varieties of approaches that have been developed over the year, which can be utilized to achieve one or more of these design objectives. Recently, the possibility of developing antenna design objective has been improved properties due to use of fractal concept. The term of the fractal geometries was originally coined by Mandelbrot [1] to describe a family of complex shapes that have self-similarity or self-affinity in their geometrical structure.

In the literature review, we have found the advantages of the fractal geometries, which support the attributes of compact size, and multi-band frequency operations. Recently, the antenna design, which has the characteristic of compact size by using the fractal technique, is known as Koch monopole antenna [2]. This fractal antenna is created by iterating the initial triangle pulse through a monopole antenna. Next, a miniaturization of loop antenna using fractal was known as Minkowski square loop antenna [3]. The fractal antenna was created by using the initial square pulse (SP) to iterative at each side of loop. The extended version of miniaturization square loop antenna was found in [4], which created by using the generator for 3/2 curve fractal to increase the electrical lengths in the fit small area.

Also, the fractal geometries still have the attribution of multi-band. The Sierpinski gasket monopole antenna in [5] was introduced by Puente. This popular antenna used the self-similarity properties of the fractal shape to translate into its electromagnetic behavior. The classic Sierpinski gasket can be generated by the Pascal triangle that was introduced in [6]. However, other antennas, which have the characteristic of multi-band created by fractal geometries, are following: Slot spiral antenna [7], multiple ring monopole antennas [8], coplanar waveguide (CPW) fed circular fractal slot antenna [9] etc.

In this paper, we used the attribute of compact size in fractal properties to design the fractal array antenna. The proposed antenna is created by using the technique of parallel feeding with fractal antenna. The antenna was designed by using the initial NP generator model [10]. The characteristics of fractal array antenna will be investigated by simulation using the full wave method of moments (MoM) software package from IE3D at the operating frequency of 2.45 GHz. Especially, the radiation pattern of the proposed antenna will be investigated to observe the magnitude of side lobe.

The organization of this paper is as follows. In section 2 and 3, a brief explanation on the antenna design will be given. Simulation and measured properties of the antenna will be discussed in section 4. Results are discussed in section 5.

II. COUPLING ANALYSIS

The NP generator model, as shown in Figure 1, is introduced to explain the iteration of the proposed antenna. The iteration depth W is smaller than a/3 [3]. In the proposed paper, the iteration depth W of the NP generator model is approximately 0.222a. The details of designed fractal antenna with NP generator model are described in [10].

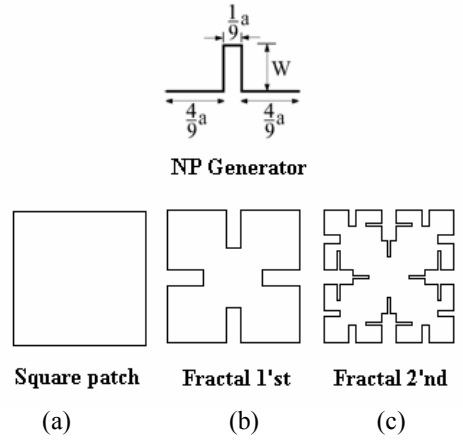

Figure 1. The NP generator model for (a) square patch, (b) first iteration, and (c) second iteration of fractal antenna.

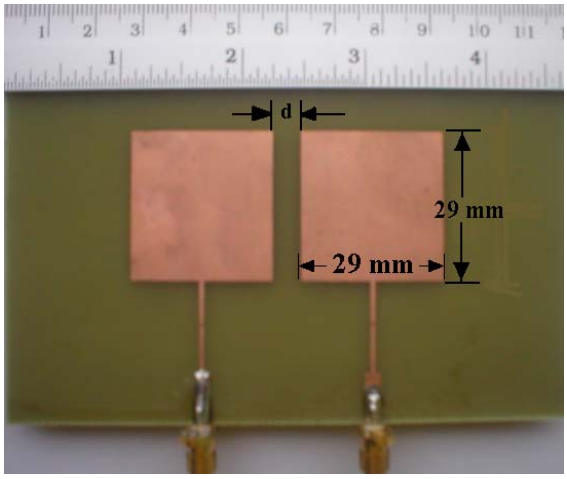
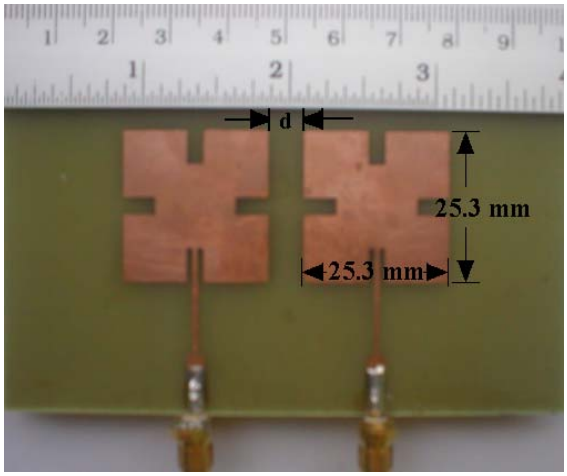
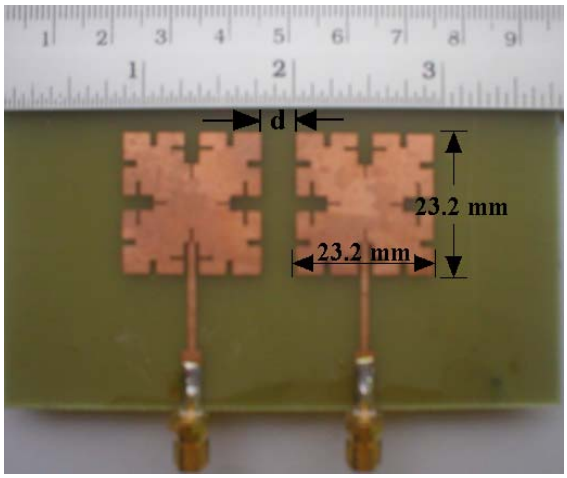


(a)



(b)



(c)

Figure 2. Experimental coupling coefficient of the antennas: (a) square patch, (b) the first iteration of fractal antenna, and (c) the second iteration of fractal antenna.

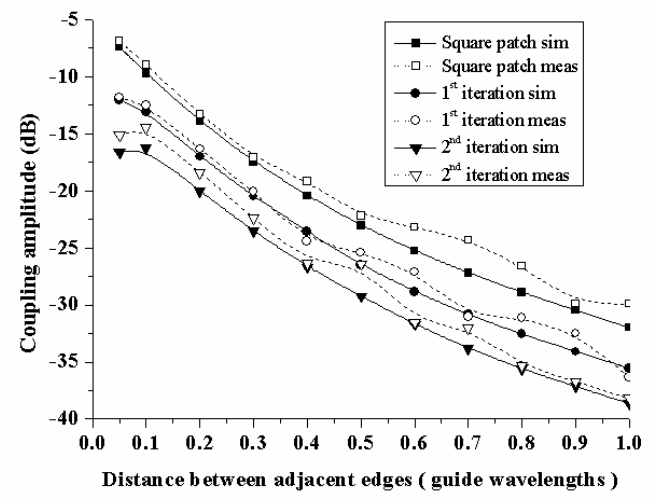


Figure 3. Coupling coefficients of all antennas.

Earlier designing the fractal array antenna, we have to investigate the coupling coefficient of the square patch antenna, 1st iteration of fractal antenna, and 2nd iteration of fractal antenna. Also, the substrate of 1.6 mm thick with dielectric constant of 4.1 was used in the experiment of coupling coefficient. The test of coupling coefficient S_{21} of the two square patch antennas, 1st iteration of fractal antennas, and 2nd iteration of fractal antennas were done with distance (d) between adjacent edges of the antennas, as shown in Figure 2. The distances (d) are following: 0.05λg, 0.1 λg, 0.2 λg, 0.3 λg, 0.4λg, until to λg.

Figure 3 shows that the simulation agrees well with the measurement. It can be clearly observed that the coupling coefficient will be reduced with the increment of the distance between adjacent edges of the antennas. The results indicate that the coupling of the fractal antennas with NP generator model is smaller than that of square patch antenna at the same distance.

III. ARRAY ANTENNA COFIGURATION

The fractal element mentioned previous section is used to create a 2x1 array antenna. The matching circuit and the array element are both on the same layer, as depicted in Figure 4. The material of the substrate is FR4 with dielectric constant 4.1, and the thickness of the substrate is 1.6 mm. The T-junction was used to design the power divider as to provide equal amplitude and in-phase feeding for each radiator. The radiator dimensions of the square patch array antenna, the 1st iteration, and the 2nd iteration of fractal array antenna, as shown in Figure 4, are 61x29 mm^2, 53.6x25.3 mm^2, and 49.4x23.2 mm^2, respectively. Also, the distance between adjacent edges of radiator is set to be 3 mm, which is 0.05λg. Therefore, the radiator dimensions of the 2nd iteration of 2x1 fractal array antenna with NP generator model is 35.21% smaller compared to the 2x1 array antenna of square patch.

Figure 6. Measured radiation pattern of 2x1 array antenna at 2.45 GHz. (a) xz-plane and (b) yz-plane.

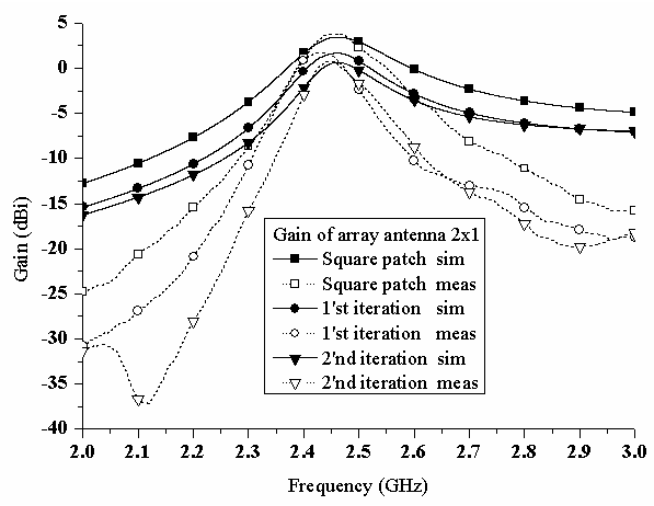

Figure 7. Simulated and Measured gain of 2x1 array antenna at 2.45 GHz.

IV. Results of Simulation and Experiment

The simulated and measured return loss of 2x1 array antennas are depicted in Figure 5. As the results show that the operating frequency of 2x1 array antennas are occurred at 2.45 GHz. Also, the simulation return losses agree well with the measured return losses. Figure 6 shows the measured radiation pattern of the 2x1 array antennas. The black lobe in the X-Z plane and Y-Z plane of 2x1 fractal array antenna with 2nd iteration NP generator model is smaller than that of the 2x1 array antenna with square patch about 5 dB. The maximum gains of radiation patterns in X-Z plane and Y-Z plane are approximately occurred at 0 degree at the resonance frequency of 2.45 GHz. Observing the results, the 3-dB beam width of the 2x1 fractal array antennas is approximately 60 degree for the measured radiation patterns. In Figure 7 depicts that the peak gains of simulation and measurement, which they occur at the operating frequency of 2.45 GHz. The peak gains of simulation are similar to that of measurement. In the simulation and measurement, the peaks gain of 2x1 array antenna with square patch, 1st iteration and 2nd iteration of fractal antenna are approximately 3 dB, 2 dB, and 1 dB, respectively.

V. Conclusion

In this paper, the experimental of the 2x1 fractal array antennas with the NP generator model have been investigated. The dimensions of the proposed antenna are approximately 35.21 % smaller than the 2x1 array antenna using square patch. The back lobe of 2x1 array antennas with square patch can be reduced approximately 5 dB, as using 2nd iteration of NP generator model. The radiation pattern of fractal array antennas are still similar to the direction radiation pattern, which have peaks gain about 2 dB, and 1 dB, respectively, for the 1st iteration and 2nd iteration of NP generator model. The 3-dB beam width of 2x1 fractal array antennas are approximately 60 degree larger than that of 2x1 array antenna with square patch.

***Abstract*— In this paper, a new compact planar inverted-F antenna (PIFA) applicable to WLAN 802.11 b/g and bluetooth applications is proposed. The proposed antenna is a CPW-fed slot antenna with inverted-F shaped tuning stub on a FR-4 substrate, which is compact, cost-effectively and precisely to manufacture, with an omni-directional pattern and a sufficient bandwidth for all of above mentioned WLAN and bluetooth standards. The experimental results of the constructed prototype are presented, and are also compared with commercial software tool.**

I. INTRODUCTION

The use of the 2.4 GHz industrial, scientific, and medial (ISM) band is be coming an important means of wireless communications including WLAN 802.11 b/g and buletooth applications. These demands have stirred significant renewed interest in antenna design particularly at the ISM bands. Therefore, the development of appropriate antenna designs is imperative. Many antenna structures for ISM bands have been presented. [1]-[2]. An antenna printed on a substrate has some advantages compared to other antennas, like the planar inverted-F antenna (PIFA). It is usually cheaper and more precisely to manufacture.

In recent years, the demand for compact handheld communication devices has grown significantly. Devices having internal antennas have appeared to fill this need. Antenna size is a major factor that limits device miniaturization. In the past few years, new designs based on PIFA antennas have been used for handheld wireless devices because these antennas have low-profile geometry and can be embedded into the devices. Several antennas for mobile and WLAN communications devices are based on PIFA [3]-[6]. These kinds of inverted-F antennas printed on a dielectric substrate are shorted to the ground plane on the other side of the dielectric substrate. In this case, such inverted-F strip antennas can not be easily integrates in the printed circuit board of the system.

In this paper, a slot antenna with inverted-F shaped tuning stub printed on a FR-4 dielectric substrate and fed by a coplanar waveguide line is proposed. By using the inverted-F shaped tuning stub in a single layer, the proposed antenna no via hole is required in short circuiting the inverted-F strip to the ground plane. Furthermore, the opened and shorted sections of inverted-F tuning stub are fed toward center by feed line, which decreases the required area for the proposed design. Details of the design considerations of the proposed antenna and experimental results of the constructed prototype are presented.

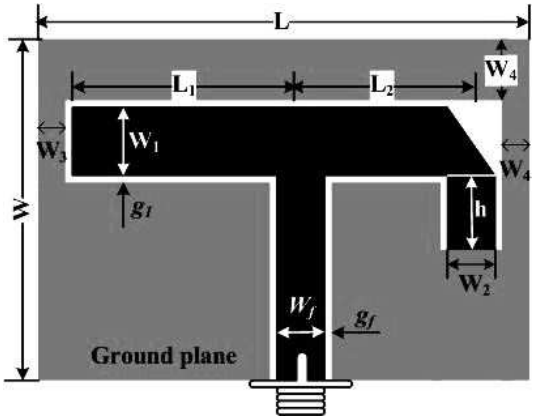

Fig. 1. Geometry of the proposed CPW-fed slot antenna with inverted-F shaped tuning stub.

II. ANTENNA DESIGN AND DISCUSSION

The configurations of the new compact CPW-fed slot antenna with inverted-F shaped tuning stub are depicted in Fig. 1. In this study, an inexpensive FR-4 substrate of thickness 1.6 mm and relative permittivity 4.4 was used for the dielectric substrate. The inverted-F tuning stub has a width of W_1, a length of L_1 for open section, and consists of a vertical shorting strip width and length of W_2 and h, respectively. A 50-Ω CPW feed line, having a signal strip of width W_f and a gap of distance g_f, is used to excite the slot. The spacing between the inverted-F tuning stub and edge of the ground plane is g_1. The miter of shorting strip is used to avoid right angle microstrip bend, which results in a poor current flow on tuning stub. The antenna has overall dimensions (W×L) of 28.3 mm× 30.1 mm.

In the study, the antenna of the proposed design for application in the WLAN 2.4 GHz band was studied. The design center frequency was chosen at 2.45 GHz, the center frequency of the WLAN 2.4 GHz band (2400-2483.5 MHz) or about 84

TABLE I

RESONANT FREQUENCY, INPUT IMPEDANCE, AND BANDWIDTH CHARACTERISTICS AS A FUNCTION OF THE GEOMETRICAL PARAMETERS

Parameters	$W_1\uparrow$	$W_2\uparrow$	$W_3\uparrow$	$W_4\uparrow$	$L_1\uparrow$	h↑
Resonant Frequency	↓	↓	↑	↑	↓	↓
Input impedance	↑	↑	↓	↓	↑	-
Bandwidth	-	↑	-	↓	↑	-

MHz. With the desired center operating frequency known, the total length L_1+ L_2+h of the inverted-F tuning stub can be first determined to be approximately one-quarter wavelength of the center operating frequency. For this reason, the total length of the inverted-F tuning stub was adjusted to be 21.04 mm. Also note that, in this design, the length of the shorting strip was selected to be 3.29 mm only (about 0.027λ) to achieve a lower height for the proposed antenna. Then, by the tuning the length L_1 of the open section of the inverted-F tuning stub and adjusting the width W_1, good impedance matching over wide frequency range can be achieved for the proposed design.

To achieve the best matching and enhance bandwidth performance, the length, width, and height of the inverted-F tuning stub and ground plane parameters are optimized. The trend of resonant frequency, input impedance, and bandwidth characteristics of each frequency is analyzed as a function of geometry parameters, as given in Table I. By observing from Table I the influence of various parameters on antenna performances, it can be seen that all parameters affect the resonant frequency of the antenna. As W_1, W_2, L_1, and h increased, the resonant frequency decreased, and vice versa. This was expected, since the height, h, and the length L_1, affect the total length of the PIFA. On the other hand, as W_4 increased, the resonant frequency so increased. Three parameters of the antenna including W_2, W_4, and L_1 affect the bandwidth of the proposed antenna. The size of the ground plane (W, L, W_2, W_3, and W_4) to a great extent also affects the resonant frequency, impedance matching, and radiation patterns. In addition, the calculated dimensions were also obtained by IE3D simulation software. The proposed antenna can be further enhances by adjusting those parameters.

The optimized design parameters for the proposed antenna are W_f = 2.73 mm, W = 28.3 mm, L = 30.1 mm, W_1 = 5.6 mm, W_2 = 3 mm, W_3 = 2.1 mm, W_4 = 1.5 mm, L_1 = 18.18 mm, L_2 = 2.86 mm, h = 3.29 mm, g_f = 0.3 mm, and g_1 = 0.6 mm.

III. SIMULATION AND EXPERIMENTAL RESULTS

In the study, a prototype of the optimal design for application in WLAN/bluetooth band was constructed as shown in Fig. 2. The characteristics impedance of the antenna were measured by an HP8510C network analyzer. Fig. 3 presents the comparison of the measured and simulated return loss S_{11} against frequency. From the obtained results, it is clearly seen that the bandwidth for WLAN 2.4 GHz band is obtained. We can see a very good agreement of the simulation and measurement results. The measured 10-dB bandwidth is about 100 MHz from 2400 to 2500 MHz.

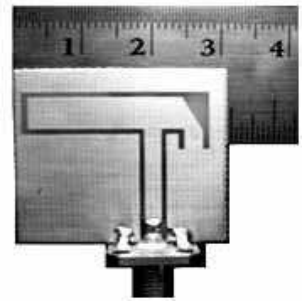

Fig. 2. Photograph of the fabricated prototype antenna.

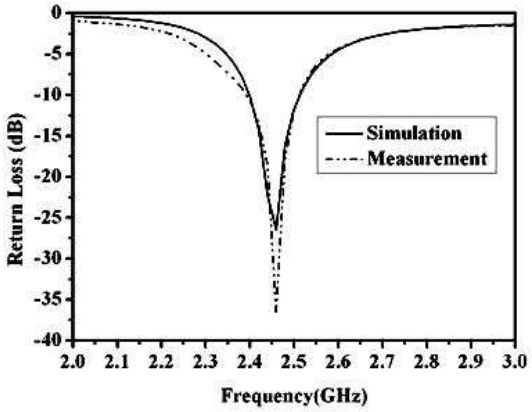

Fig. 3. Measured and simulated return losses for the proposed antenna with W_f = 2.73 mm, W = 28.3 mm, L = 30.1 mm, W_1 = 5.6 mm, W_2 = 3 mm, W_3 = 2.1 mm, W_4 = 1.5 mm, L_1 = 18.18 mm, L_2 = 2.86 mm, h = 3.29 mm, g_f = 0.3 mm, and g_1 = 0.6 mm.

The radiation characteristics of the proposed antenna have also been studied. Fig. 4 and 5 plot the simulated radiation patterns at 2.45 GHz. It is noted that the pattern in the azimuthal plane is omni-directional, which makes the proposed antenna have large radiation coverage in practical applications. The simulation results show that it is possible to build the proposed antenna, which does not only a compact size but furthermore fulfills the demand on bandwidth, impedance and radiation pattern. Other radiation pattern parameters of the proposed antenna as simulated are presented in Table II. The measured antenna gain for oprating frequencies within the WLAN band is also presented in Fig. 8. The proposed antenna shows a peak antenna gain of 2.55 dBi at 2.45 GHz.

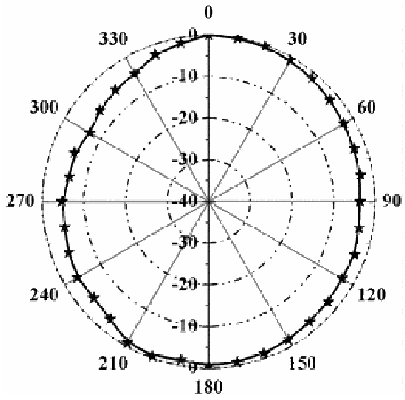

Fig. 7. Measured radiation pattern of the proposed antenna at 2.45 GHz in azimuth plane.

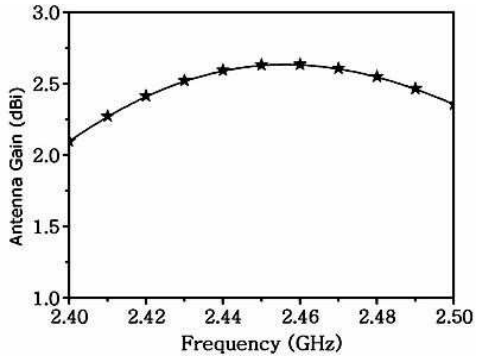

Fig. 8. Measured antenna gain for operating frequencies within the WLAN band.

IV. Conclusion

In this paper, a new compact CPW-fed slot antenna with inverted-F shaped tuning stub that covers the WLAN 802.11 b/g and bluetooth applications is proposed. And a prototype suitable for WLAN/bluetooth applications has also been constructed and studied. The constructed prototype meets the bandwidth requirement of the WLAN/bluetooth 2.4 GHz band, and good radiation characteristics have also been observed. In addition, the proposed antenna is compact, efficient, easy and cost-effective to manufacture.

***Abstract*-This paper presents the throughput for wireless local area network (WLAN) used orthogonal diversity antenna, vertical and horizontal polarization, and improved signal by multiuser detection of slow frequency hopping/multicarrier direct sequence-code division multiple access (SFH/MC DS-CDMA) technique over Nakagami fading channel. The numerical results presence in the number of path, number of carrier, Nakagami-m fading factor and number of user. The throughput of WLAN with Nakagami fading is analyzed. The throughput improvement of the SFH/MC DS-CDMA system. We have considered two type of antenna, including vertical polarization, horizontal polarization, and have analyzed their throughput versus offer load. We also found the vertical polarization is better than the horizontal polarization for throughput in all of the results.**

I. INTRODUCTION

More and More stations connect to wireless local area network (WLAN) and demand for various wireless services, which support data, voice, and video, has rapidly increased. The costs for installation and relocation for cable LAN's cable have increased. However, wireless LAN's offer many advantages in installation, maintenance, and relocation from the view point of cost and efficiency.

One of important research issues in wireless LAN is the design and analysis of MAC protocols or signal or antenna for high speed data bit rate. MAC protocols or orthogonal diversity for wireless communication have been widely studied[1-2]. There are also many for MAC protocols in fading channel. In this paper, we present analytical approach for the channel throughput by slow frequency hopping multicarrier direct-sequence code division multiple access (SFH/MC DS-CDMA) for two types of antenna: vertical polarization, horizontal polarization. We analyze and compare the throughput with each other.

II. CSMA/CA PROTOCOL

In the CSMA/CA protocol, a packet generated at a user terminal is transmitted to the access point after the carrier sensing becomes "idle." The CSMA/CA timing as shown in figure 1.

Here, when the expectation time length of a "busy" period as defined as $\overline{B}$ and the expectation time length of an "idle" period is defined as $\overline{I}$, and the expectation time length in which no collision occurs and packets are successfully transmitted is defined as $\overline{U}$, the throughput S is give by

$$S_{CSMA/CA} = \frac{\overline{U}}{\overline{B}+\overline{I}} \tag{1}$$

We obtain the sum of the expectation of useful transmission time as [3]

$$\overline{U} = \frac{M\left[1-(1-g)\right](1-g)^{M-1}}{1-(1-g)^{M}} + \left(\frac{1}{(1-g)^{(TP/a)M}}-1\right).\sum_{n=1}^{M}\left\{\left[np(1-p)^{n-1}+\left(np(1-p)^{n-1}(1-g)^{M-n}+(1-p)^{n}(M-n)g(1-g)^{M-n-1}\right).\frac{(1-p)^{n}(1-g)^{M-n}}{1-(1-p)^{n}(1-g)^{M-n}}\right]\cdot\binom{M}{n}\left[1-(1-g)^{(TP/a)}\right]^{n}(1-g)^{(TP/a)(M-n)}\right\} \tag{2}$$

and the expected value of the busy and the idle period as [3].

$$\overline{B}+\overline{I} = f\left[1-(1-g)^{M}\right]+1+a+\frac{a}{1-(1-g)^{(TP/a)M}}\left\{\left[1-(1-g)^{(TP/a)M}\right](1+a+f)+\left[a.\left(\sum_{k=1}^{\infty}\left\{(1-p)^{k}-(1-g)^{(TP/a)}\left[(1-p)^{k}-(1-g)^{k}\right]\right\}^{M}-(1-g)^{(TP/a)M}\right).\sum_{k=1}^{\infty}(1-g)^{kM}\right)\right]\right\}+\frac{a}{\left[1-(1-g)^{M}\right]} \tag{3}$$

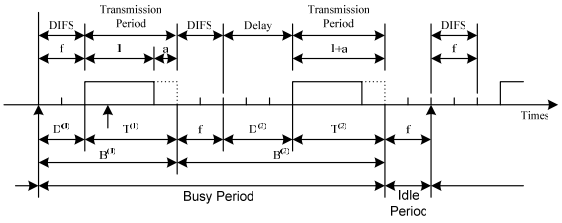

Figure1. Basic CSMA/CA Protocol

III. SYSTEM DESCRIPTION

A. *Transmitter Model*

The original bit stream having a bit duration of T_b is first serial-to-parallel (S-P) converted, as seen in the schematic, yielding U_k parallel stream. The assignment of bits to the activated subcarrier is controlled by the constant-weight code. Depending on the specific aims of the system design, we can

assign every $U_k - th$ bit to the same subcarrier and in this parallel system the bit-duration is hence extended to $T = U_k T_b$. This assists in mitigating the inter-symbol-interference (ISI) in a high-bit rate transmission scheme. Alternatively, the proposed parallel system can be used to maintain $T = T_b$ in each subchannel, hence assisting in high-rate or variable-rate transmission upon employing a different number of subcarriers, as well as highlight duration our further discourse. Theoretically, Q number of different information rate can be generated by changing the weight of code. The direct-sequence (DS) spread, transmitted signal of orthogonal diversity for the k[th] user can be formulated as

$$s_v(t) = \sum_{i=0}^{\infty}\sum_{k=1}^{K}\sum_{uk=1}^{Uk}\sqrt{\frac{2Eb_{uk}}{T}}b_{uk}^{(k)}(t)\cdot e^{j2\pi f_{v,uk}^{(k)}t}s_{uk}^{(k)}\left(t-iT_c\right) \quad (4)$$

$$s_h(t) = \sum_{i=0}^{\infty}\sum_{k=1}^{K}\sum_{uk=1}^{Uk}\sqrt{\frac{2Eb_{uk}}{T}}b_{uk}^{(k)}(t)\cdot e^{j2\pi f_{h,uk}^{(k)}t}s_{uk}^{(k)}\left(t-iT_c\right) \quad (5)$$

The DS spreading waveform the subcarrier frequency set and the phase angles introduced in the carrier modulation process. Let T_c the chip duration of the DS spreading waveform and $N = T_b/T_c$ of the symbol duration. We assume the FH interval is T_h and the number of data bit $N = T_b/T$, transmitted per hop is a positive integer, which is strictly larger than 1, implying slow FH

B. Nakagami Channel Model

We consider a frequency-selective multipath channel [4], whose complex low-pass impulse response for subcarrier u_k of user k is given by

$$h_{uk}^{(k)}(\tau) = \sum_{l=0}^{L-1}\alpha_{uk,l}^{(k)}e^{-j\phi_{uk,l}^{(k)}}\delta(t-lT_c) \quad (6)$$

Where l_pT_c is the relative delay of the $l_p - th$ path of user k with respect to the main path, the $\left\{\phi_{u_k,l_p}^{(k)p}\right\}$ are independent identically distributed (iid) random variables uniformly distributed in the interval $(0,2\pi)$, whilst the L_p tap weights $\left\{\alpha_{u_k,l_p}^{(k)}\right\}$ are independent Nakagami-m random variables of orthogonal diversity with a pdf of

$$P_{\alpha_l}(\alpha_l) = \frac{2m_l^{m_l}\alpha_l^{2m_l-1}}{\Omega_l^m\Gamma(m_l)}\exp\left(-\frac{m_l\alpha_l^2}{\Omega_l}\right) \quad (7)$$

Where $\Gamma(\cdot)$ represents the gamma function, and m is the Nakagami-m fading parameter. The parameter $\Omega_{u_k,l_p}^{(k)}$ is the second moment of $\alpha_{u_k,l_p}^{(k)}$

C. Receiver Model

In the traditional orthogonal diversity system, vertical and horizontal are used as an independent transmission channel. It means that the data streams transmitted in both antennas are uncorrelated

Let the user be the user-of-interest and consider the conventional matched filter base correlating receiver with maximum ratio combining (MRC). Upon exploiting the knowledge of the FH patterns, detection can be implement by demodulating only the U_k active subcarreir , or alternatively, all Q subcarrier can be always demodulated, while only U_k MRC output are according ti the FH patterns used for detection. The kth user employs BPSK modulation to transmit equal probability data bit $b_k(i)\in\{\pm 1\}$, at a common bit rate $1/T$. The number of matched filter in fig. are matched to the reference user's CDMA code used for spreading in the subband associated with the Q number of subcarrier, and assume to have achieved time synchronization. If we assume perfect estimates of channel tap weight and phase are variable, in order to synchronize the L number of path signals used correlating receiver for vertical polarization and horizontal can be expressed as

$$r_v(t) = \sum_{i=0}^{\infty}\sum_{k=1}^{K}\sum_{uk=1}^{Uk}\sum_{l=1}^{L}\sqrt{\frac{2E_{b_{uk}}}{T}}b_{uk,l}^{(k)}\alpha_{uk,l}^{(k)}e^{j2\pi f_{uk,l}^{(k)}(t)}.s_{uk,l}^{(k)}\left(t-iT-\tau_{uk,l}^{(k)}\right)+n(t) \quad (8)$$

$$r_h(t) = \sum_{i=0}^{\infty}\sum_{k=1}^{K}\sum_{uk=1}^{Uk}\sum_{l=1}^{L}\sqrt{\frac{2E_{b_{uk}}}{T}}b_{uk,l}^{(k)}\alpha_{uk,l}^{(k)}e^{j2\pi f_{uk,l}^{(k)}(t)}.s_{uk,l}^{(k)}\left(t-iT-\tau_{uk,l}^{(k)}\right)+n(t) \quad (9)$$

where $\alpha_{u_k,l_p}^{(k)}$ are independent Nakagami-m random variables of orthogonal diversity, horizontal and vertical, for horizontal polarization can be express as[5]

$$\alpha_h = \frac{\sin\gamma-\left(\kappa-j60\lambda\sigma-\cos^2\gamma\right)^{1/2}}{\sin\gamma+\left(\kappa-j60\lambda\sigma-\cos^2\gamma\right)^{1/2}} \quad (10)$$

and for vertical polarization[5]

$$\alpha_v = \frac{(\kappa-60\lambda\sigma)\sin\gamma-\left(\kappa-j60\lambda\sigma-\cos^2\gamma\right)^{1/2}}{(\kappa-60\lambda\sigma)\sin\gamma+\left(\kappa-j60\lambda\sigma-\cos^2\gamma\right)^{1/2}} \quad (11)$$

where $\kappa=\varepsilon/\varepsilon_0$ is the relative permittivity of the earth. σ is conductivity of the earth (good earth)[8].

IV. THROUGHPUT ANALYSIS

In this section, we consider multi-user detection of slow frequency hopping multicarrier direct sequence code division multiple access (multi-user detection of SFH/MC DS-CDMA) technique for vertical and horizontal polarization over Nakagami fading channel. The frequency hopping pattern are controlled by a set of constant-weight code $C(Q,U_k)$. A set of U_k number of active FH subcarrier frequencies from the Q outputs of the frequency synthesizer.

The average bit error probability for multi-user detection of SFH/MC DS-CDMA can be expresses as[4].

$$\overline{P_e} = \sum_{x=0}^{X-1} \binom{X-1}{x_h} . P_h^{x_h} \left(1-P_h\right)^{X-1-x_h} . P_b\left(x_h\right) \qquad (12)$$

where $0 \le x_h \le X-1$ and P_h is the probability of a hit from an interfering signal, which can be expressed as.

$$P_h\left(x\right) = \frac{U_k}{Q} \qquad (13)$$

where U_k represents the weight of constant - weight code employed. The multi-user detection of SFH/MC DS-CDMA designed supporting data, voice, and video service. We assume furthermore that each user transmits independently. Then average probability of a hit can be expressed as

$$P_h = \frac{1}{QM} \sum_{i=0}^{M} U_i \qquad (14)$$

Q-function can be represented as

$$Q\left(x\right) = \frac{1}{\pi} \int_0^{\frac{\pi}{2}} \exp\left(-\frac{x^2}{2\sin^2\theta}\right) d\theta \qquad (15)$$

the latter Q-function representation has the advantage of having finite integration limits that are independent of the argument x. Hence (15) allows us to obtain a convenient analytical BER expression for the scenario, where the multipath channel output are not identically distributed. In this paper, $\overline{\gamma}$ represents the average received signal-to-noise ratio (SNR) given by:

$$\overline{\gamma} = \left[\frac{q\left(L_p,\eta\right)}{2N_p}\left(\frac{L_p-1}{L_p}\right) + \frac{K_h, q\left(L_p,\eta\right)}{3N_p} + \left(\frac{2\Omega_0 E_b}{N_o}\right)^{-1}\right]^{-1} \qquad (16)$$

each received signal magnitude are same. The received signal magnitude $\gamma_l = \Omega_{q,l}^2 / \Omega_0$ represents by probability density function (pdf) over Nakagami fading channels for number of path L[th] are

$$P_{\gamma_{u_k}}\left(\gamma\right) = \frac{m^m \gamma_l^{m-1}}{\overline{\gamma}_l^m \Gamma\left(m\right)} \exp\left(-\frac{m}{\overline{\gamma}_l}\gamma_l\right) \qquad (17)$$

the average bit error probability over Nakagami fading channel for number of path L[th] can be expressed as.

$$P_b = \frac{1}{\pi} \int_0^{\frac{\pi}{2}} \prod_{l=1}^{L} \left(\frac{\sin^2\theta}{\sin^2\theta+1}\right)^{mL} d\theta \qquad (18)$$

according to the analysis of Alouini and Goldsmith [5] can be expressed in a closed -form as

$$P_b\left(x_h\right) = \sqrt{\frac{\gamma}{1+\gamma}} \frac{\Gamma\left(mL+\frac{1}{2}\right)}{\Gamma\left(mL+1\right)} \bullet {}_2F_1\left(1, mL+\frac{1}{2}; mL+1; \left(1+\gamma\right)^{-1}\right) \qquad (19)$$

where ${}_2F_1\left(a,b;c;z\right)$ is the hypergeometric function defined as[4].

$${}_2F_1\left(a,b;c;z\right) = \sum \frac{a_k b_k z^k}{c_k k!} \qquad (20)$$

Finally, the throughput of CSMA/CA protocol by multiuser detection of SFH/MC DS-CDMA technique for orthogonal diversity over Nakagami fading channel, we can be calculate throughput by (1) and (12) defined as

$$S = S_{CSMA/CA}\left(1-\overline{P_e}\right)^L \qquad (21)$$

for (21) L is the number of bit per packet to transmission.

V. NUMERICAL RESULT

The numerical results are shown and the throughputs of two types of polarization diversity (vertical polarization and horizontal polarization in the good earth's condition) are compared in this section. Figure2. plots the throughput versus offer load of the orthogonal diversity of the proposed SFH/MC DS-CDMA system with respect to the number of path $l_p = 1, 2, 3, 4, 5$. Note that as the number path increase, the throughput does increase a lot but the throughput does decrease when the offer load is high. Figure3. shown the throughput versus offer load are compared for two types of polarization diversity. We note that throughput increase when number of carrier increase $Q = 1, 2, 4, 8, 16$ in low-offered traffic while the throughput decreases in high-offered traffic. Figure4. Note that curves in presented, the throughput over Nakagami fading channel increase if offered load is low traffic, while the throughput in Nakagami fading channel model decrease when traffic increase. Figure5. Note that curves in presented, the throughput versus offer load with number of user, the throughput decrease in high user and high offered load. Finally, we note that the vertical polarization is more appropriate than the horizontal diversity in CSMA/CA by multiuser detection of SFH/MC DS-CDMA for wireless LAN system.

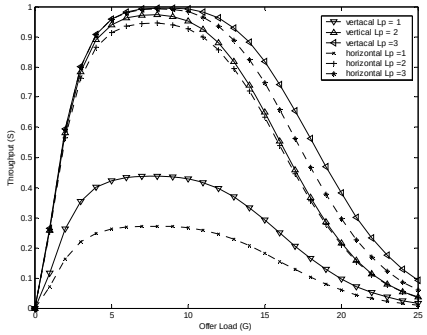

Figure 2. Throughput versus offer load for varying of the number of path (L_p=1,2,3 m=1 Q=1 User=32 SNR=15 dB)

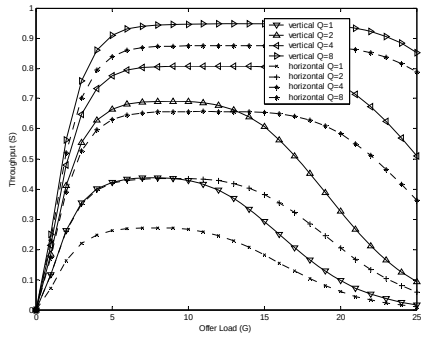

Figure 3. Throughput versus offer load for varying of the number of carrier (L_p=1 m=1 Q=1,2,4,8 User=32 SNR=15 dB)

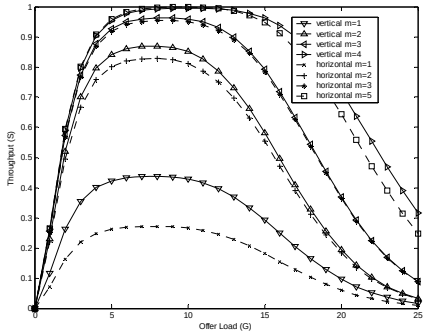

Figure 4. Throughput versus offer load for varying of the Nakagami-m fading factor (L_p=1 m=1,2,3,4 Q=1 User=32 SNR=15 dB)

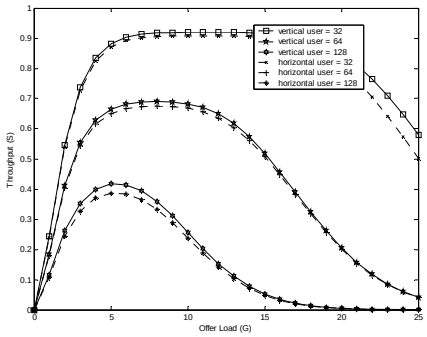

Figure 5. Throughput versus offer load for varying of the number of User (L_p=1 m=1 Q=4 User=32,64,128 SNR=15 dB)

VI. CONCLUSION

This paper presents the throughput for wireless local area network (WLAN) for orthogonal diversity antenna (vertical and horizontal polarization) by multiuser detection of SFH/MC DS-CDMA technique over Nakagami fading channel. The numerical results presence in the number of path, number of carrier, Nakagami-m fading factor and number of user. The throughput of WLAN with Nakagami fading is analyzed. The throughput improvement of the SFH/MC DS-CDMA system. We have considered two type of antenna, including vertical polarization, horizontal polarization, and have analyzed their throughput versus offer load. We also found the vertical polarization is better than the horizontal polarization for throughput in all of the results.

The main contributions of this are twofold: 1.the improvement of an analytical for the throughput of MAC protocol using multi-user detection SFH/MC DS-CDMA system for wireless LAN over Nakagami fading channel. 2.the throughput channel comparison for two types of antenna, vertical and horizontal polarization.

***Abstract*-This paper proposes the Multi linear chirp frequency hopping (MLC/FH) technique for GSM system to increase the user capacity. Simulation used Rayleigh fading channel model for performance compare between GH-GSM and MLC/FH-GSM. From result shows that highest user capacity can increase up to 48 times to compare with conventional GSM system and also up to 6 times to compare with FH-GSM system.**

I. INTRODUCTION

The Global System for Mobile Communication (GSM) is very popular in the world. The number of GSM users increased very quickly, so providers have to increase number of base station more that system to increase the investment. Frequency Hopping (FH) [1] used to increase the GSM users capacity. This method can increase number of users more than GSM 8 times. The frequency allocations are defined to be used in different function as shown in Figure 1. In each frequency band, FDMA technique was employed to divide the whole bandwidth into sub-carrier frequency bandwidth of 200 kHz and each carrier frequency will be divided by using TDMA technique into 8 timeslots, and Ts_0 timeslot is used for signaling [2]. GSM system set time duration of each channel is 577 μs and hop to other frequency before through next frame. FH-GSM consisted of 2 types is Cyclic hopping and Pseudo random hopping as shown in Figure 2[3].

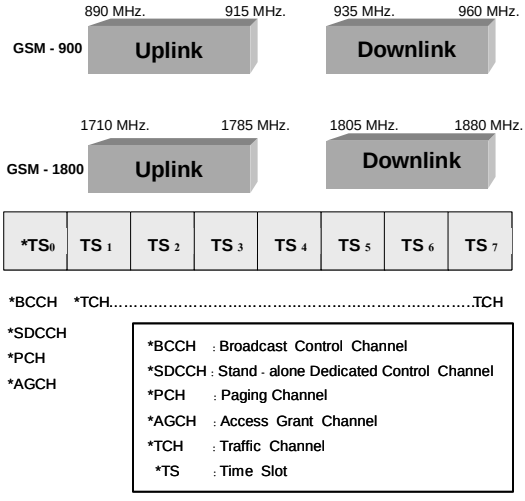

Figure 1.Frequency allocation and channel configuration of GSM

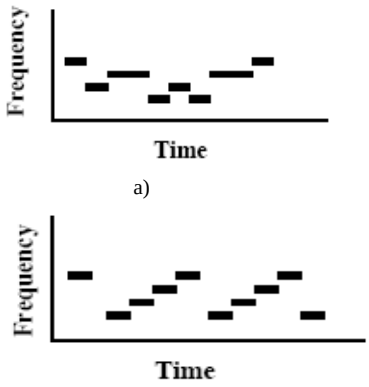

Figure 2.Hopping pattern of FH–GSM
a) Cyclic hopping b) Pseudo random hopping.

Pseudo-random hopping used random frequency hop, it have problem of frequency collision between hop. In causes from 2 users hop at the same time by accident and also in at that time it has synthesized at the same frequency thus it cannot detect user. The result is probably of data error that is affect to this system because the causes are happen always. Cyclic hopping can be solved for frequency collision but not good for the security. From [4] proposed technique prevents a collision problem. This paper used Pseudo-random hopping scheme for GSM because this scheme is good security and solved the collision problem by MLC technique. MLC/FH technique not only prevents a collision problem, it can be increase number of user per time slot and performance.

II. PRINCIPLE AND THEORY

A. FH – GSM System

In FH–GSM transmitted data in pattern of TDMA frame [1]. GSM base station will transmit frequency of each time duration channel (577 μs) and a frequency will hop to next channel after that. Uplink and downlink used the same frequency.

FH-GSM hopped 64 sequences. The type of hopped is Mobile Allocation Index Offset (MAIO) and Hopping Sequence Number (HSN).

MAIO have many data in sequence of frequency and also it can initial of hopped frequency. HSN has 64 sequences that function informed index of sequence. Actually frequency will

be changed as random when HSN not equal zero (0). If HSN equal zero (0), the system will be hopped in cyclic mode.

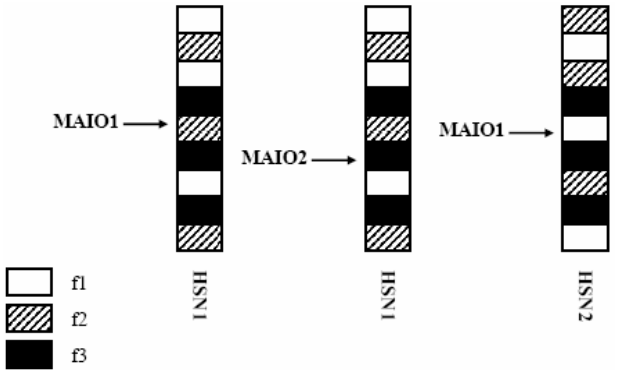

Figure 3.Hopping patterned with 3 MAIO frequencies for each HSN.

Advantage of hopped pattern in Figure 3 is set condition with different MAIO. It haven't problem about collision from hopping such as the frequency hopped of HSN is difference and MAIO is the same value. In case of HSN is same value both frequency and time channel. It will occur the interference at $1/n$ of burst signal, where n is the different value of hopped frequency sequence. It can decrease the performance of system as follow Figure 4.

Disadvantage of system is reduce one of channel because used one channel for BCCH (Broadcast Control Channel) which the base station use this channel for BSIC (Base Station Identification Code) and frequency decoding. Thus the system can be served the lower amount of users.

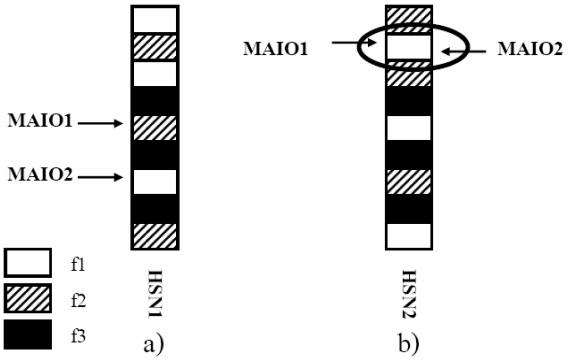

Figure 4.Hopping patterned with 3 MAIO frequencies in case the same of HSN a) No collision problem b) Collision problem.

III. PROPOSED SYSTEM

Transmitter and receiver block diagram of propose system as shown in Figure 5and Figure 6 respectively.

Figure 5 shows information of each user is passed to MLC modulator with parallel channel and multiplied with hopper. After that the data will sum in order to send Tx. Signal in the same antenna. MLC modulate signal as follow [4].

$$s_{mc}(t) = s_f(t) + s_b(t) \tag{4}$$

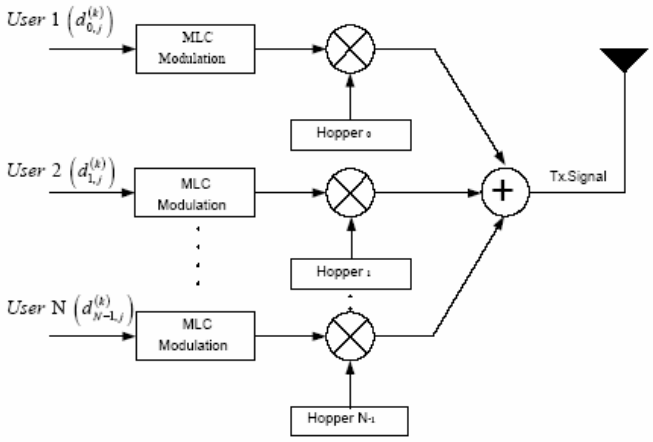

Figure 5.Block diagram of MLC/FH–GSM transmitter .

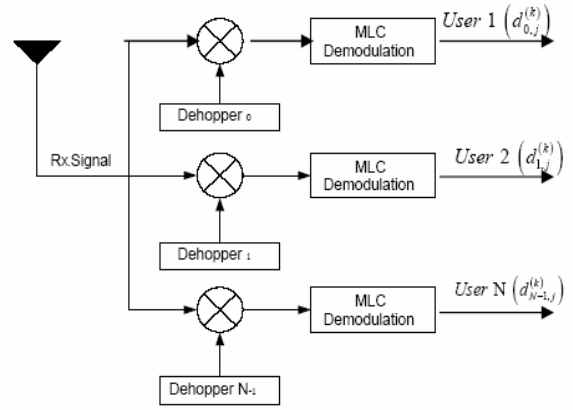

Figure 6.The block diagram at receiver side of MC – FH – GSM system.

And adjust center frequency value of f_{ch} as follow.

$$f_{ch} = f_{ch1} + (l_m - 1)W_d, \quad l_m = 1, 2, ..., L \tag{5}$$

$$L = 2^k \tag{6}$$

Where l_m is the hop level of user m
L is the number of all hop level
f_{ch} is center frequency of hop band
f_{ch1} is the center frequency of first(1^{st}) hop

From (5) can be write MLC/ FH –GSM signal for every user as follow [4,5,6].

$$\sum_i \sum_{l=0}^{N-1} \sum_{n=-\infty}^{\infty} \sum_{m=1}^{M} d_{l,i}^{(m)} s_{mf}(t)\, p_{T_h}(t - nT_h) \tag{7}$$

$$s_{mf}(t) = s_{mff}(t) + s_{mfb}(t) \tag{8}$$

$$s_{mff}(t) = A\cos\Big[2\pi\big(f_{ch1} + (l_m - 1 - b(t)/2)W_d\big)t + b(t)\mu_{fm}\pi t^2\Big], 0 \le t \le mT_c \tag{9}$$

$$\mu_{fm} = \frac{(M+1-m)\Delta f}{mT_c} \tag{10}$$

$$s_{mfb}(t) = A\cos\Big[2\pi\big(f_{ch1} + (l_m - 1 + b(t)/2)W_d - b(t)m\Delta f\big)(t - mT_c) + b(t)\mu_{bm}\pi(t - mT_c)^2\Big], \quad mT_c \le t \le T_h \tag{11}$$

$$\mu_{bm} = \frac{m\Delta f}{(M+1-m)T_c} \tag{12}$$

$$T_c = \frac{T_h}{(M+1)} \tag{13}$$

$$\Delta f = \frac{W_d}{(M+1)} \tag{14}$$

$$b(t) = \begin{cases} 1 & \text{Up Chirp} \\ -1 & \text{Down Chirp} \end{cases}, 0 \le t \le T_h \tag{15}$$

Where μ_{fm} is front chirp slope of user m^{th}

μ_{bm} is back chirp slope of user m^{th}

m is user sequence

T_h is hop bit duration

T_c is total time

$p(t)$ is unit amplitude pulse of duration T_c period

$d_{l,i}^{(m)}$ is the binary sequence of user m^{th}

l is the sequence of bit

i is the amount of bit

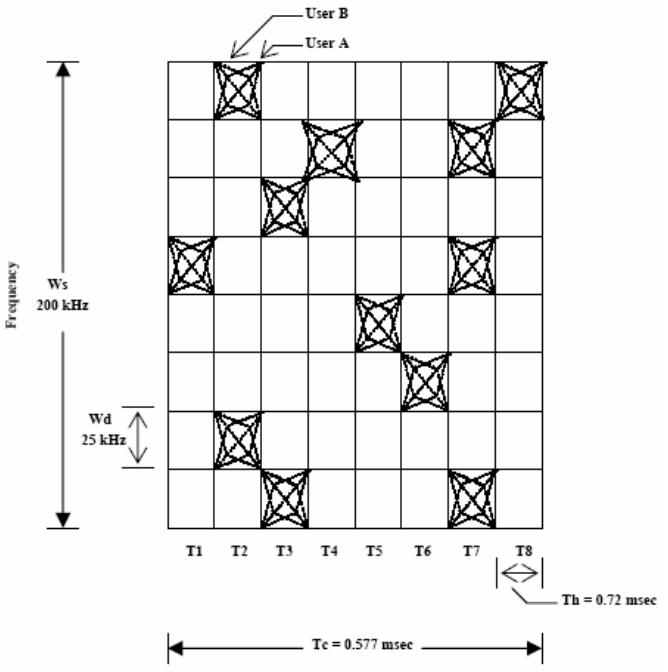

Figure 7 Solution for frequency code collision problem of users A and B in MLC/FH-GSM system

Receiver used dehopper for alternatives hopper process and MLC demodulator which correlator circuit used compared receive signal with reference signal. Figure 7 shows MLC/FH-GSM transmit signal in time–frequency domain of two users which has the same frequency as same as figure 4. It can see that occurred frequency collision of user A and user B will be different frequency characteristic. MLC demodulator can be separated the collision signal of each user and does not occur the error signal in users A and B. Figure 7.shows dispreading signal convert to data modulate band. This signal will compare and analyze of each bit in MLC demodulator. It can be decrease the error probability in MC-FH-GSM system.

IV. Experiment And The Results [7,8,9]

Simulate model of MC/FH-GSM detail of frequency and time bit duration as figure 8. Simulation result of performance and number of user compared between FH-GSM and MLC/FH-GSM as shown in figure 8, 9, 10 and 11.

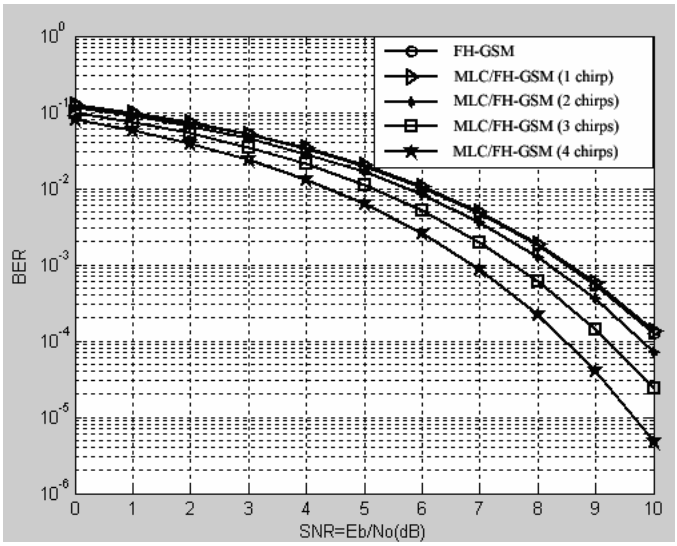

Figure 8.Performance comparative between MLC/FH-GSM and FH-GSM.

Figure 8 Show the experimental result from setting the number of user at 48. By vary SNR parameter that the BER value of FH-GSM system has the highest values when compare with MLC/FH-GSM system because of the FH-GSM system was defined frequency channel less than MLC/FH-GSM system.

Figure 9 shows performance as increase the number of user. When number of user increased continuously, FH-GSM system cannot support this amount of user because this system limited by number of hop. This result shows chirp modulation will make the system can serve the increase number of users. Because of chirp modulation will decrease the causes of data collision. Figure 10 can be estimated maximum of chirp rate which use in system not more than 12 chirps.

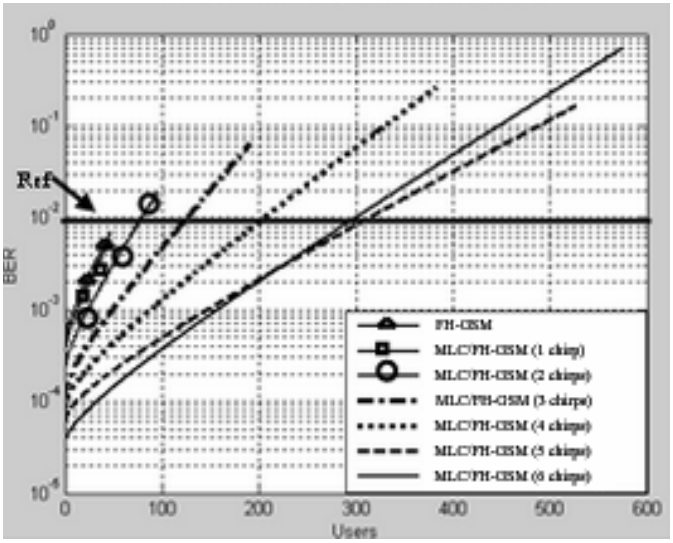

Figure 9.BER and Number of user compare between FH-GSM and MLC/FH-GSM system (Ideal channel).

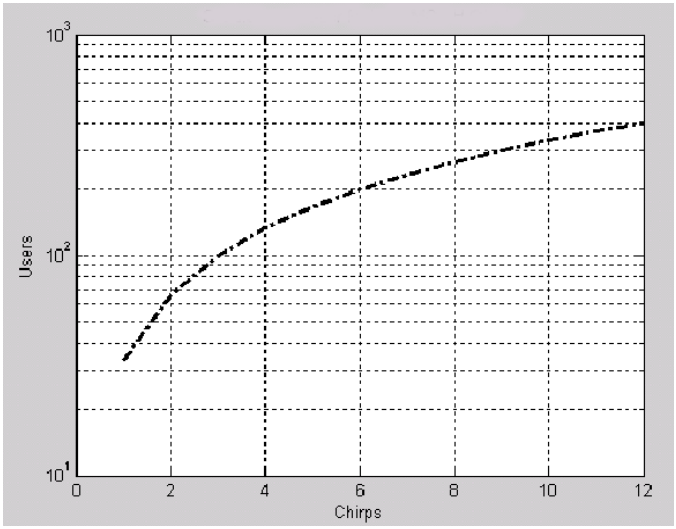

Figure 10.Comparative between number of GSM user and number of chirp.

Figure 10 shows comparative between maximum number of users and chirp rate. The initial period the trend of graph slope is increased. When the chirp rate is increased the slope will reduce continuously because number of user nearly upper bound.

Figure 11 shows performance of FH-GSM and MLC/FH-GSM over Rayleigh fading channel model. Performance of FH-GSM and MLC/FH-GSM system have lower value than experiment result in figure 9, because will have more signal distortion in system.

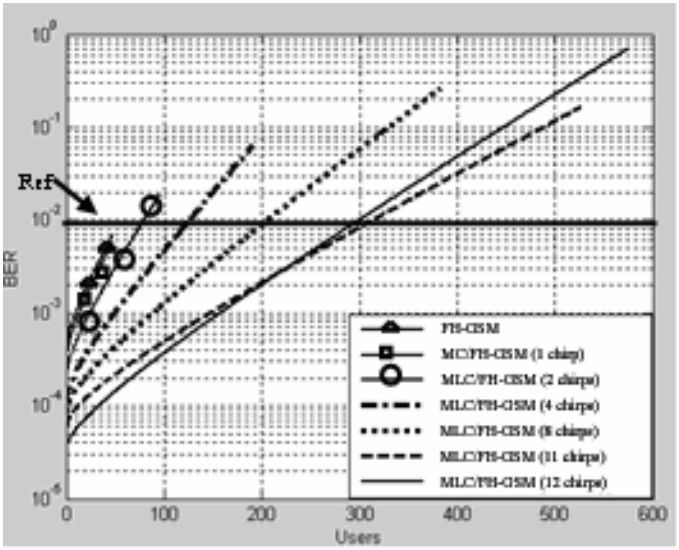

Figure 11.BER and number of user comparative between FH-GSM and MLC/FH-GSM system over Rayleigh Fading Channel model.

V. CONCLUSION

This paper proposes MLC/FH-GSM technique to solve collision problem and increase the performance greater than Pseudo random hopping FH-GSM system. Also this technique can serve the increasing of users. From result the chirp rate not more than 12 chirps. For voice service as BER 10^{-2}, the MLC/FH-GSM user capacity up to 6 times to compare with FH-GSM system.

Abstract— **The major drawback of orthogonal frequency division multiplexing (OFDM) is large Peak-to-Average Power Ratio (PAPR) of its time domain signal. To overcome the PAPR problem on OFDM signal, various PAPR reduction methods have been proposed up to today. The most of PAPR reduction methods such as PTS and SLM methods require the side information which causes the degradation of transmission efficiency and complexity of transmitter and receiver. In this paper, we propose a novel PAPR reduction method which can improve the PAPR performance without side information. The feature of proposed method is to use the common weighting factor over a frame including preamble and data symbols in which the common weighting factor is multiplied to the frequency domain signal over a frame so as to reduce the PAPR performance. The data symbols in one frame can be demodulated at the receiver by using the estimated common weighting factor. The common weighting factor can be estimated together with the channel frequency response by using the preamble symbol located at the start of every frame. This paper presents various computer simulation results to verify the effectiveness of proposed method in the multi-path fading channel.**

I. INTRODUCTION

Recently the OFDM technique has been received a lot of attentions especially in the field of wireless communications because of its efficient usage of frequency bandwidth and robustness to the multi-path fading. From these advantages, the OFDM has already been adopted as the standard transmission techniques in the wireless LAN systems and the terrestrial digital broadcasting system [1-2]. The OFDM technique is also considering as one of the candidate transmission techniques for the next generation of wireless communications systems. One of the limitations of using OFDM technique is the larger peak to averaged power ratio (PAPR) of its time domain signal as compared with the conventional single carrier transmission techniques [3]. The larger PAPR signal would cause the severe degradation of bit error rate (BER) performance due to the inter-modulation noise occurring in the non-linear amplifier.

From the above background, the PAPR reduction method is recognized as one of the essential research topics for the OFDM method employed in the wireless communications sytems. Up to today, various kinds of PAPR reduction methods were proposed including the selected mapping method (SLM) [4] and partial transmit sequence method (PTS) [5-6]. Although both methods can achieve the better PAPR performance by controlling the phase of data sub-carriers, these two methods are required to inform the phase information controlled for the data sub-carriers to the receiver as the side information (SI). Since the side information is required to inform the receiver symbol by symbol by using the data or control channels with the higher signal quality for the correct demodulation of data information at the receiver, the transmission efficiency would be degraded relatively and the system complexity would be increased. The size of side information depends on the number of clusters and discrete phases employed in the SLM or PTS methods. To improve the PAPR performance, the larger number of clusters and discrete phases are required which lead the proportional increasing of side information size.

To overcome the problem for the conventional PAPR reduction methods with using the side information, we propose a novel PAPR reduction method which is required no side information. The feature of proposed method is that the PAPR performance can be improved by multiplication of common weighting factor over one frame including preamble and data symbols. The original data can be recovered by multiplying the inverse of common weighting factor employed at the transmitter. In the proposed method, the inverse of weighting factor can be estimated by using the preamble symbols which are usually used in the conventional OFDM system to establish the synchronization of received signal and to estimate the channel frequency response of fading channel.

In the following of this paper, Section II presents the system model to be used in the following evaluations. Section III presents the proposed PAPR reduction method. Section IV presents the various computer simulation results to verify the effectiveness of the proposed method, and we draw some conclusions in Section V.

II. SYSTEM MODEL

In the OFDM system, the modulated signal in the frequency domain is converted to the time domain signal by using *IFFT*. The time domain signal for *l-th* symbol at *k-th* sample is given by the following equation.

$$y_{(l,k)} = \frac{1}{\sqrt{N}} \sum_{n=0}^{N-1} X_{(l,n)} e^{j\frac{2\pi kn}{N}} \quad (1)$$

where N is the number of *IFFT* points and $X_{(l,n)}$ is the modulated data for *l-th* symbol at *n-th* sub-carrier. Here the PAPR performance for the sampled time domain signal can be given by,

$$PAPR(dB) = 10\log_{10}\left(\frac{\max_{k=0\sim N-1}\left[\left|y_{(l,k)}\right|^2\right]}{E\left[\left|y_{(l,k)}\right|^2\right]}\right) \quad (2)$$

where $E[\ ]$ represents the average power of signal. The time domain OFDM signal given in (1) is input to the non-linear amplifier after adding the guard interval (GI). The output of non-linear amplifier can be expressed by the following equation.

$$s_{(l,k)} = F[\left|y_{(l,k)}\right|]e^{j\{\arg(y_{(l,k)})\}} \quad (3)$$

where, $F[\ ]$ represent the AM/AM conversion characteristics of non-linear amplifier. The non-linear amplifier assumed in this paper is the Solid State Power Amplifier (SSPA) of which input and output relationship is modeled by the following equation.

$$F[\rho] = \frac{\rho}{[1+(\rho/A)^{2r}]^{1/2r}} \quad (4)$$

where, ρ is the amplitude of input signal, A is the saturated output level, and r is the parameter to decide the non-linear level. The phase conversion of the non-linear amplifier is assumed to be linear in the following evaluation. Figure 1 shows the AM/AM conversion characteristics of SSPA when changing the parameter of r in (4).

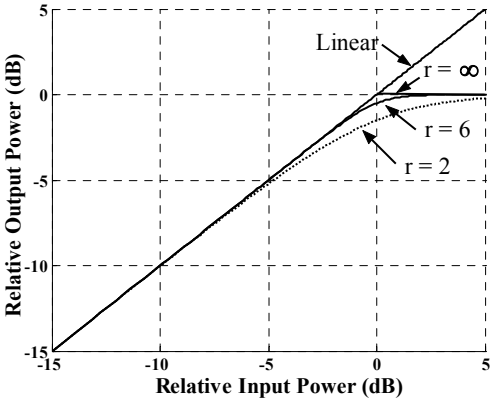

Figure. 1. Input-output relationship of SSPA.

III. PROPOSAL OF PAPR REDUCTION METHOD

A. Transmitter

Figure 2 shows the burst frame format to be used in the proposed OFDM system. In Fig. 2, two preamble symbols are inserted before the transmission of data symbols, which are used in the synchronization of received signal and the estimation of channel frequency response including the common weighting factor multiplied over a frame at the transmitter so as to reduce the PAPR performance. Fig.3 (a) shows the structure of proposed transmitter. By reoffering this figure, the following presents the detail of proposed method.

In the proposed method, the transmission time domain signal for *l-th* symbol of *k-th* sample at *i-th* iteration is given by the following equation.

$$\begin{aligned}\bar{y}_{(l,k)}^{(i)} &= \frac{1}{\sqrt{N}}\sum_{n=0}^{N-1}\left(X_{(l,n)}^{(i-1)}\cdot e^{j\theta_n^{(i)}}\right)e^{j\frac{2\pi kn}{N}} \\ &= \frac{1}{\sqrt{N}}\sum_{n=0}^{N-1}X_{(l,n)}^{(i)}\cdot e^{j\frac{2\pi kn}{N}}\end{aligned} \quad (5)$$

where $e^{j\theta_n^{(i)}}$ is the common weighting factor for *n-th* sub-carrier at *i-th* iteration, which is decided so as to reduce the PAPR performance. Here it should be noted that the common weighting factor at *n-th* sub-carrier has the same value over one frame. In the proposed method at the next *(i+1)-th* iteration, the new weighting factor for each symbol will be independently decided so as to obtain the better PAPR performance than the previous iteration. After the determination of weighting factor for all symbols including the preamble symbols, the new common weighting factor over one frame will be decided by taking the ensemble average of weighting factor obtained for all symbols.

As for the method to decide the weighting factor for each symbol, this paper employs the basic concept of time-frequency domain swapping algorithm [7]. In this algorithm, the error signal is calculated by the following equation in which the sampled time domain signal is detected as the error signal only when its amplitude level is greater than a certain reference level of *S*.

$$e_{(l,k)}^{(i)} = \begin{cases}\bar{y}_{(l,k)}^{(i)} & if\ \left|\bar{y}_{(l,k)}^{(i)}\right| \geq S \\ 0 & if\ \left|\bar{y}_{(l,k)}^{(i)}\right| < S\end{cases} \quad (6)$$

where the reference level *S* is decided on the basis of the average power of time domain signal. Here, the error signal is the composite signal in the time domain which includes all the larger amplitude level than the reference level of *S*. To determine the weighting factor for each sub-carrier, the time domain error signal given by (6) is converted to the frequency domain signal by *FFT*, which is given by the following equation.

$$E_{(l,n)}^{(i)} = \frac{1}{\sqrt{N}}\sum_{k=0}^{N-1}e_{(l,k)}^{(i)}\cdot e^{-j\frac{2\pi kn}{N}} \quad (7)$$

The weighting factor for *l*-th symbol at *n*-th sub-carrier can be obtained by subtracting the phase of error signal given in (7) from the phase of original signal. Then, the frequency domain signal to be used at the next iteration $(i+1)$ is given by the following equation.

$$X_{(l,n)}^{(i+1)} = \left|X_{(l,n)}^{(i)}\right|e^{j\arg\left\{X_{(l,n)}^{(i)}-E_{(l,n)}^{(i)}\right\}} \quad (8)$$

The weighting factor of *n*-th sub-carrier for *l-th* symbol can be given by,

$$\theta_{(l,n)}^{(i+1)} = \arg\left\{X_{(l,n)}^{(i+1)}\right\} - \arg\left\{X_{(l,n)}^{(i)}\right\} \quad (9)$$

After finishing the above procedures over all symbols, the common weighting factor for *n-th* sub-carrier at the *(i+1)-th* iteration can be obtained by taking the ensemble average for the weighting factors obtained for all symbols, which is given by,

$$\theta_n^{(i+1)} = \arg\left\{\sum_{l=1}^{L}e^{j\theta_{(l,n)}^{(i+1)}}\right\} \quad (10)$$

where L is the frame length including preamble and data symbols. By using (10), the transmission time domain signal at the *(i+1)-th* iteration can be given by,

$$\begin{aligned}\overline{y}_{(l,k)}^{(i+1)} &= \frac{1}{\sqrt{N}}\sum_{n=0}^{N-1}\left\{X_{(l,n)}^{(i)}\cdot e^{j\theta_n^{(i+1)}}\right\}\cdot e^{j\frac{2\pi kn}{N}} \\ &= \frac{1}{\sqrt{N}}\sum_{n=0}^{N-1}X_{(l,n)}^{(i+1)}\cdot e^{j\frac{2\pi kn}{N}}\end{aligned} \tag{11}$$

In the proposed method, the procedures from (5) to (11) are repeated up to reach either the predetermined target PAPR performance or predetermined number of iterations.

B. Receiver

Figure 3 (b) shows the structure of receiver for the proposed method. The received signal $r_{(l,k)}$ for *l-th* symbol at *k-th* sample after down converter (D/C) and Analog to Digital converter (A/D) as shown in Fig.3 (b) can be given by the following equation.

$$r_{(l,k)} = \overline{y}_{(l,k)}^{(P)} \otimes h_{(l,k)} + n_{(l,k)} \tag{12}$$

where $s_{(l,k)}$, $h_{(l,k)}$ and $n_{(l,k)}$ show the transmitted OFDM signal, impulse response of multi-path fading channel and Additive White Gaussian Noise (AWGN) for *l-th* symbol at *k-th* sample, respectively. In (12), P is the number of iterations which provides the best PAPR performance at the transmitter. The received signal as given in (12) is converted to the frequency domain signal by using *FFT* which is expressed by the following equation.

$$R_{(l,n)} = X_{(l,n)}^{(P)}\cdot H_{(l,n)} + N_{(l,n)} \tag{13}$$

where, $R_{(l,n)}$, $X_{(l,n)}^{(P)}$, $H_{(l,n)}$ and $N_{(l,n)}$ show the received signal, transmitted signal, channel frequency response and noise component in the frequency domain, respectively.

When assuming the operation environments such as the radio LAN system, the time variance of channel frequency response can be assumed as sufficiently slow because of very lower terminal moving speed. From this fact, the channel frequency response over one frame can be considered as static. Accordingly, the channel frequency response estimated by using two known preamble symbols inserted at the start of every frame can be used in the equalization of data symbols over one frame. The channel frequency response which is improved the estimation accuracy by taking the ensemble average over two preamble symbols, can be obtained by the following equation.

$$\begin{aligned}\hat{H}_n &= \frac{1}{2}\sum_{l=1}^{2}\left\{X_{(l,n)}^{P}\cdot H_n + N_{(l,n)}\right\}/X_{(l,n)} \\ &= H_n\cdot e^{j\psi_n} + N_{(l,n)}/X_{(l,n)}\end{aligned} \tag{14}$$

where $\hat{H}_n$ is the estimated channel frequency response affected by the common weighting factor and noise component. Here, $e^{j\psi_n}$ can be given by following equation.

$$\psi_n = \sum_{i=1}^{P}\theta_n^{(i)} \tag{15}$$

From (14), it can be observed that the common weighting factor can be estimated in the frequency domain by using preamble symbols. By using (14), the original data signal can be demodulated by employing the same manner as the conventional frequency domain equalization method in which the common weighting factor multiplied at the transmitter and the multi-path fading multiplied in the channel can be removed from the received signal.

IV. Performance Evaluation

This section presents the various computer simulation results to verify the performance of proposed method. The modulation method is assumed by 64QAM with coherent detection method. The multi-path fading is modeled by 16 delay paths having the exponential power delay profile with -1 dB decay constant. In the following simulations, the synchronizations both for the symbol timing and frequency offset are assumed to be established ideally by using two preamble symbols. The simulation parameters to be used in the following evaluations are shown in Table 1. In the simulations, the number of *FFT* points (N=256) is taken by 4 times larger than the number of sub-carriers (M=64) to evaluate the PAPR performance with higher accuracy.

TABLE I
SIMULATION PARAMETERS

Modulation	64QAM
Demodulation	Coherent
Allocated bandwidth	5MHz
Number of *FFT* points	256
Number of sub-carriers	64
Symbol duration	12.8us
Guard interval	1.28us
Non-linear amplifier	SSPA
Non-linear parameter of SSPA	r=2
Number of data symbols in one frame	12
Number of preamble symbols in one frame	2
Multi-path fading model	
Power delay profile	Exponential
Number of delay paths	16
Decay constant	-1 dB

Figure 4 shows the averaged PAPR performance both for the conventional OFDM and proposed methods when changing the number of iterations. The frame length is 12 symbols including 2 preamble symbols. From the figure, it can be seen that the proposed method can achieve the best PAPR performance when the number of iterations is larger than 8. The proposed method shows the better averaged PAPR performance than the conventional OFDM by 1.4 dB. From the results, the number of iterations is assumed by 8 in the following evaluations.

Figure 5 shows the PAPR performance for the conventional OFDM and proposed methods when the frame length is 12 symbols. The PAPR performance is evaluated by using the Complementally Cumulative Distribution Function (CCDF). From the figure, it can be observed that the proposed method can achieve the better PAPR performance than conventional OFDM about 1.9 dB at 10^{-1}. Here it should be noted that the degradation of BER performance of OFDM signal in the non-linear channel would be dominated by the PAPR performance at the CCDF larger than 10^{-1}.

Figure 6 shows the BER performances for the proposed and conventional OFDM methods in the multi-path fading channel when the input back-off (IBO) of non-linear amplifier is taken by -6 dB and -8 dB. From the figure, it can be observed that the proposed method can achieve much better BER performance than conventional OFDM method in the channel including the non-linear amplifier and multi-path fading.

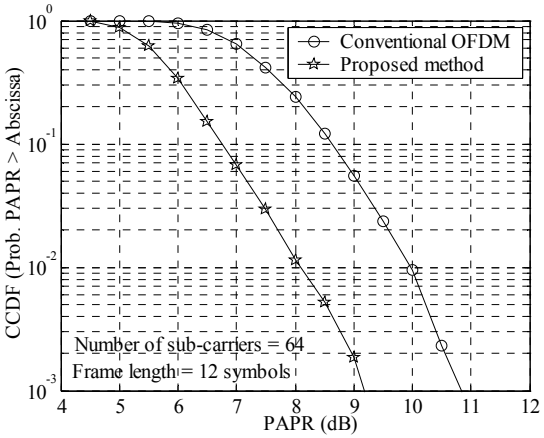

Figure. 5. PAPR performance for proposed method.

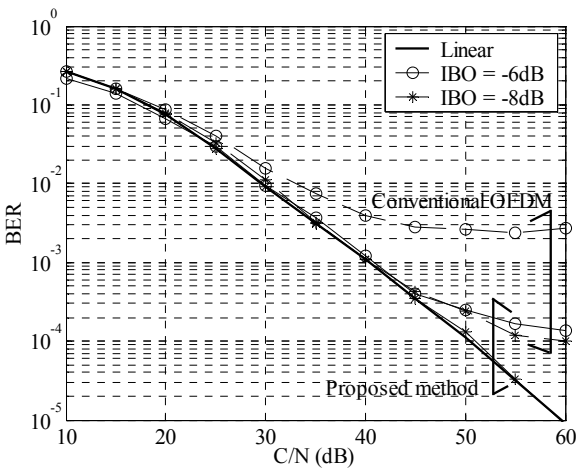

Figure. 6. BER performance of proposed method.

V. CONCLUSIONS

This paper proposed the PAPR reduction method for the OFDM signal without degradation of transmission efficiency. The feature of proposed method is to use the common weighting factor over one frame including the preamble symbols so as to improve the PAPR performance. In the proposed method, the time-frequency domain swapping algorithm is employed in the determination of common weighting factor. The common weighting factor can be removed from the received data symbols by using the frequency domain equalization. In the proposed method, the common weighting factor can be estimated together with the channel frequency response by using preamble symbols. Form this fact, the proposed method can achieve the better PAPR performance without loss of transmission efficiency. From the various computer simulation results, we confirmed that the proposed method can achieve the better PAPR performance and better BER performance than the conventional OFDM in the channel including non-linear amplifier and multi-path fading.

***Abstract*- This paper proposes BER comparison between cdmaOne (IS-95B) and CDMA2000 for voice and WWW service over Nakagami fading channel model. The change of transmission data rate which direct effect to the quality of service (QoS). The performance in case perfect power control and imperfect power control is considered. Result shows the performance can be improve with maximum ratio combining (MRC) technique at the RAKE receiver. This technique can be increased performance by increase number of antenna and finger.**

I. INTRODUCTION

Mobile service is very popular in the world, developed of digital cellular from 2G to 3G for support voice and multimedia service. IMT-2000 was provide Mbps data rate for demand application such as broadband internet access, with most countries supporting one of two competing standard asCDMA2000 and Wideband-CDMA. CDMA2000 standard builds on cdmaOne to provide an evolution path to 3G [1]. The cdmaOne consist of 2 versions as IS-95A and IS-95B (2.5G) for higher data rate. Some techniques of CDMA2000 that consisted of cdmaOne have the ability of all data transmission at the same time.

In wireless communication system, the environment effect, such as reflection, diffraction and distortion from buildings or other obstacles, resulted to be the fading of transmitted signal. This fading effect can be described according to Nakagami Fading Model.

This paper considers the bit error rate between cdma2000 with IS-95B 3 channels and cdma2000 with 1 channel by studying the data rate changing which directly affects to the quality of service.

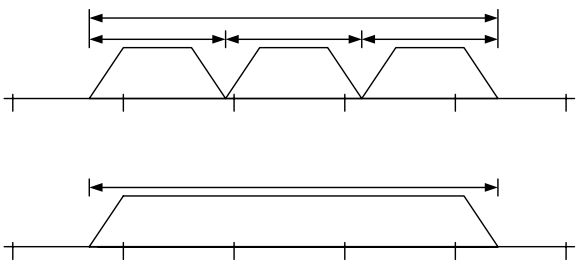

Figure 1. Frequency allocation Band of IS-95B and cdma2000 standard.

II. SYSTEM MODEL AND ANALYSIS OF SIGNAL TO INTERFERENCE SIGNAL RATIO

CDMA cellular system cell layout model consists of 19 cells for investigated interference [2] as shown in figure 2 and base station installed at the center of each cell.

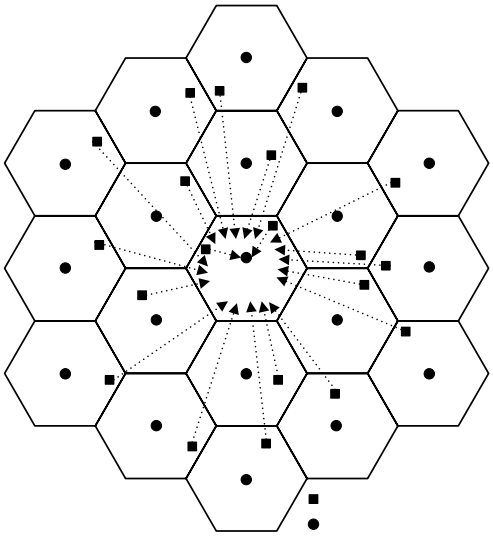

Figure 2. Model of 19 cells layout.

A. Transmitter Model

Figure 2 shows signal propagation path from the mobile subscribers to the base station and this paper assigned radius of cell is defined as 1 unit. There are k users which used the system in each cell at the same time. IS-95B and CDMA2000 transmitter uses BPSK modulation, as follow:

$$s_k(t) = \sqrt{2P}\, b_k(t)\, c_k(t) \cos(\omega_c t + \phi_k) \tag{1}$$

Where $s_k(t)$ is the transmitted of user k, P is the power of each user, ω_c is angular velocity of carrier, ϕ_k is the phase angle of user k carrier as uniform distribution at $[0, 2\pi]$

$$b_k(t) = \sum_{j=-\infty}^{\infty} b_{jk}\, p_{T_b}(t - jT_b) \quad ; b_{jk} \in \{-1, +1\} \tag{2}$$

$$c_k(t) = \sum_{j=-\infty}^{\infty} c_{jk}\, p_{T_C}(t - jT_c) \quad ; c_{JK} \in \{-1, +1\} \tag{3}$$

$b_k(t)$ is data sequence of user k which is binary pulse amplitude $(-1,+1)$ with same probability, $c_k(t)$ is code sequence of user k which is binary pulse amplitude $(-1,+1)$ with same probability, $P_{T_b}(t)$ and $P_{T_c}(t)$ is square waves with 1 unit height and pulse width equal to T_b (for bit sequence) and T_c (for chip sequence). G_p is the processing gain is equal to T_b / T_c.

B. Channel Propagation Model

By using frequency selective Nakagami-*m* fading channel [3], the model has the complex low pass equivalent impulse response for parallel signal u of user k^{th} as follow.

$$h_k^{(u)}(t) = \sum_{l=1}^{L_p} \beta_{kl}^{(u)} \exp(j\phi_{kl}^{(u)})\,\delta(t-\tau_{kl}^{(u)}) \tag{4}$$

The attenuation $\beta_{kl}^{(u)}$ in (4) has the probability density function (PDF), as follow.

$$p(\beta_{kl}^{(u)}) = M(\beta_{kl}^{(u)}, m_{kl}^{(u)}, \Omega_{kl}^{(u)})$$

$$M(R,m,\Omega) = \frac{2m^m R^{2m-1}}{\Gamma(m)\Omega^m} e^{-(m/\Omega)R^2} \tag{5}$$

Where $\Gamma(.)$ is Gamma function, m_{kl} is the Nakagami– m fading parameter of user k^{th} at signal path l and L is total number of signal paths.

C. Receiver Model

Transmit signal from each user will pass though the fading channel model. The channel consists of the amplitude attenuation (α) and delay time (from $d(t)$ to $d(t-\tau)$). The receive signal from any user, both internal and external cell stations are determined as (6).

$$r^{(q)}(t) = \sqrt{2P}\sum_{k=1}^{K}\sum_{l-0}^{L_k-1}\left\{\begin{array}{l}\alpha_{l\,k}^{(q)} c_k(t-\tau_{lk}^{(q)}) \\ b_k(t-\tau_{lk}^{(q)})\cos(\omega_c t+\varphi_{l\,k}^{(q)})\end{array}\right\} \tag{6}$$

$$+\sqrt{2P}\sum_{m=1}^{M}\sum_{l=0}^{L_k-1}\sum_{i=1}^{K}\left\{\begin{array}{l}\alpha_{l\,i}^{(q)}\left(\frac{d_{m,i}}{d_{0,i}}\right)^{\beta} c_i(t-\tau_{l\,i}^{(q)}) \\ b_i(t-\tau_{l\,i}^{(q)})\cos(\omega_c t+\varphi_{l\,i}^{(q)})\end{array}\right\} + n(t)$$

$r^{(q)}(t)$ is the received signal, P is power signal of each user from mobile subscriber to base station, $a_{lk}^{(q)}$ is amplitude attenuation of user k with branch l, τ_{lk} is delay time of user k with branch l, $\varphi_{lk}^{(q)} = \phi_k + \theta_{lk} - \omega_c \tau_{lk}^{(q)}$ is carrier phase with uniform distribution $[0, 2\pi)$, β is propagation path loss exponent (this paper is 4), $d_{0,i}$ distance from user i to home cell, $d_{m,i}$ $d_{0,i}$ distance from user i in cell m to home cell.

The receiver uses number of antenna as ξ branches, as shown in figure 3. Each branch uses the rake receiver [4] with MRC technique over J finger, as shown in figure 4 [5] and output signal as (7). From (7), the first term is the desire signal,

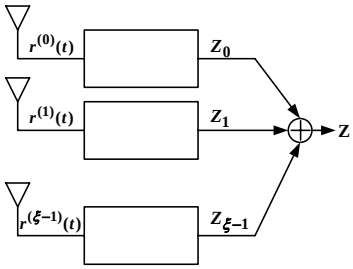

Figure 3. Receiver model at each antenna branch

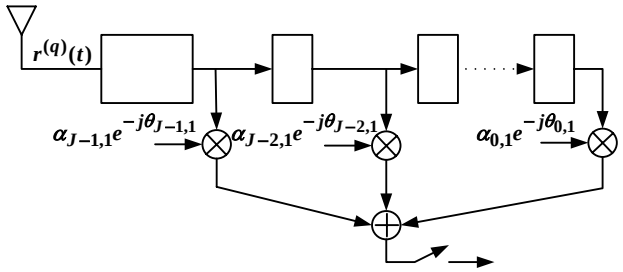

Figure 4. RAKE receive

second term is the self interference signal, third term is the interference signal from other users in cell, forth term is the interference signal from other users from the adjacent cell and the last term is AWGN(additive white Gaussian noise).

$$Z = \sum_{q=0}^{\xi-1} Z_q = \frac{\sqrt{2P}}{2}\sum_{q=0}^{\xi-1}\sum_{j=0}^{J-1} T b_0^1 \left[\alpha_{j1}^{(q)}\right]^2$$

$$+\frac{\sqrt{2P}}{2}\sum_{q=0}^{\xi-1}\sum_{j=0}^{J-1}\alpha_{j1}^{(q)}\sum_{\substack{l=0\\ l\neq j}}^{L_1-1}\left\{\begin{array}{l}\alpha_{l1}^{(q)}\cos(\varphi_{j\,l,1}^{(q)}) \\ \left[b_{-1}^1 R_{l1}(\tau_{jl}^{1,(q)}) + b_0^1 \hat{R}_{l1}(\tau_{jl}^{1,(q)})\right]\end{array}\right\} \tag{7}$$

$$+\frac{\sqrt{2P}}{2}\sum_{q=0}^{\xi-1}\sum_{k=2}^{K}\sum_{j=0}^{J-1}\left\{\begin{array}{l}\alpha_{j1}^{(q)} \\ \sum_{l=0}^{L_K-1}\left\{\begin{array}{l}\alpha_{l\,K}^{(q)}\cos(\varphi_{j\,l,1}^{(q)})\lambda \\ \left[b_{-1}^k R_{lk}(\tau_{jl}^{k,(q)}) + b_0^k \hat{R}_{lk}(\tau_{jl}^{k,(q)})\right]\end{array}\right.\end{array}\right\}$$

$$+\frac{\sqrt{2P}}{2}\sum_{q=0}^{\xi-1}\sum_{m=1}^{M}\sum_{i=1}^{K}\sum_{j=0}^{J-1}\left\{\begin{array}{l}\lambda\alpha_{j1}^{(q)} \\ \sum_{l=0}^{L_k-1}\left\{\begin{array}{l}\alpha_{li}^{(q)}\left(\frac{d_{m,i}}{d_{1,i}}\right)^{\beta}\cos(\varphi_{j\,l,1}^{(q)}) \\ \left[b_{-1}^i R_{li}(\tau_{jl}^{i,(q)}) + b_0^i \hat{R}_{li}(\tau_{jl}^{i,(q)})\right]\end{array}\right.\end{array}\right\}$$

$$+\int_{jTc}^{T+jTc} n(t)\alpha_{j1}^{(q)} c_1(t-jTc)\cos(\omega_c t+\varphi_{l1}^{(q)})dt$$

Analysis of signal to interference ratio (SIR) in this paper is consisted of 2 cases as perfect and imperfect power control.

D. Perfect power control SIR

Complete power control (V=0) is controlled power signal between mobile subscriber and base station, example of power

control by position of users is near or far from base station, SIR is calculated by

$$SIR = \frac{P_{Signal}}{\sigma^2_{Total}} \tag{8}$$

$$\sigma^2_{Total} = \sum_{q=0}^{\xi-1}\sum_{j=0}^{J-1}\left\{(E(I^2_{SI,j})+E(I^2_{MAI,j})+E(I^2_{OCI,j})+E(I^2_{NI,j})\right\} \tag{9}$$

$$= \sum_{q=0}^{\xi-1}\sum_{j=0}^{J-1}\left(\alpha^{(q)}_{j1}\right)^2\left\{\begin{array}{l}\dfrac{\left(\sqrt{2P}\right)^2T^2}{4}\dfrac{\sum_{l=0,l\neq j}^{L_1-1}\left(E(\alpha^{(q)}_{l1})^2\right)}{2Gp} \\ +\dfrac{\left(\sqrt{2P}\right)^2T^2}{4}\dfrac{\sum_{k=2}^{K}\lambda\sum_{l=0}^{L_k-1}\left(E(\alpha^{(q)}_{lk})^2\right)}{3Gp} \\ +\dfrac{\left(\sqrt{2P}\right)^2T^2}{4}\dfrac{1}{9}\dfrac{\sum_{m=1i=1}^{M}\sum^{K}\lambda\sum_{l=0}^{L_k-1}\left(E(\alpha^{(q)}_{li})^2\right)}{3Gp} \\ +\dfrac{N_oT}{4}\end{array}\right\}$$

For perfect power control, average power of each user is equal to $\left(\sqrt{2P}\right) = A$. First term in (7), can get the desire signal. Then take (9) in (8) to get (10) as

$$SIR_{per} = \frac{\sum_{q=0}^{\xi-1}\sum_{j=0}^{J-1}\left(\alpha^{(q)}_{j1}\right)^2}{\Omega_0\left\{\begin{array}{l}\sum_{l=0}^{L-1}e^{-l\delta}\dfrac{1}{2Gp}+\dfrac{(K-1)\lambda}{3Gp}\sum_{l=0}^{L-1}e^{-l\delta} \\ +\dfrac{K\lambda}{3Gp}\dfrac{M}{9}\sum_{l=0}^{L-1}e^{-l\delta}+\dfrac{No}{2Eb\Omega_0}\end{array}\right\}} \tag{10}$$

E. Imperfect power control SIR

From (10), if signal level from each user is not equals to A level and changed to A_k level. The probability density function [5] as follow:

$$p(A_k) = \frac{1}{2V}, \qquad A-V \le A_k \le A+V \tag{11}$$

Where V is maximum signal level of A_k. So the SIR value in (10) is:

$$SIR_{imper} = \frac{\sum_{q=0}^{\xi-1}\sum_{j=0}^{J-1}\left(\alpha^{(q)}_{j1}\right)^2}{\Omega_0\left\{\begin{array}{l}\sum_{l=0}^{L-1}e^{-l\delta}\left(1+\dfrac{V^2}{3A^2}\right)\dfrac{1}{2Gp} \\ +\sum_{l=0}^{L-1}e^{-l\delta}\dfrac{(K-1)\lambda}{3Gp}\left(1+\dfrac{V^2}{3A^2}\right) \\ +\sum_{l=0}^{L-1}e^{-l\delta}\dfrac{K\lambda}{3Gp}\dfrac{M}{9}\left(1+\dfrac{V^2}{3A^2}\right)+\dfrac{N_0}{2E_b\Omega_0}\end{array}\right\}} \tag{12}$$

$$Y = \frac{1}{\Omega_0}\sum_{j=0}^{J-1}\left(\alpha^{(q)}_{j1}\right)^2 \tag{13}$$

$$H = \frac{\xi}{\left\{\begin{array}{l}\sum_{l=0}^{L}e^{-l\delta}\left(1+\dfrac{V^2}{3A^2}\right)\dfrac{1}{2Gp}+\sum_{l=0}^{L}e^{-l\delta}\dfrac{(K-1)\lambda}{3Gp}\left(1+\dfrac{V^2}{3A^2}\right) \\ +\sum_{l=0}^{L}e^{-l\delta}\dfrac{K\lambda}{3Gp}\dfrac{M}{9}\left(1+\dfrac{V^2}{3A^2}\right)+\dfrac{N_0}{2E_b\Omega_0}\end{array}\right\}} \tag{14}$$

III. Analysis of Average Bit Error Rate

The cellular CDMA system performance analysis in this paper can be used the probability of error [3].

$$P_e(\sqrt{HY}) = \frac{1}{2}erfc(\sqrt{HY}) \tag{15}$$

$$erfc(x) = \frac{2}{\sqrt{\pi}}\int_x^{\infty}e^{-t^2}dt \tag{16}$$

Y_j is the attenuation from multipath signal which is Nakagami distribution power 2 and normalized as:

$$Y_j = \frac{\alpha_j^2}{\Omega_0} \tag{17}$$

The PDF of Y_j is,

$$P_{y_j}(Y_j) = \frac{Y_j^{(m-1)}}{\Gamma(m)}\left(\frac{m}{\lambda_j}\right)^m e^{(-m/\lambda_j)Y_j}, \quad Y_j \ge 0 \tag{18}$$

Assumed Y_j is not depend on statistic value, so

$$P_{y1,y2,.....,y_j}(Y_1,Y_2,.....Y_j) = \prod_{j=1}^{J}p_{y_j}(Y_j) \tag{19}$$

From (19), considering each channel in case of cdma2000 with N=3, bandwidth = 1.25 MHz and code rate = 1.2288 Mcps (3 x IS-95B) as:

$$P_{e(total)} = P_{e(f1)} + P_{e(f2)} + P_{e(f3)} \tag{20}$$

$P_{e(total)}$ is the statically independent event

$$\begin{aligned}P_{e(3\times IS-95B)} &= (P_{e(f1)} + P_{e(f2)} + P_{e(f3)}) \\ &-(P_{e(f1)}\bullet P_{e(f2)})-\left(P_{e(f1)}\bullet P_{e(f3)}\right) \\ &-(P_{e(f2)}\bullet P_{e(f3)}) \\ &+(P_{e(f1)}\bullet P_{e(f2)}\bullet P_{e(f3)})\end{aligned} \tag{21}$$

Incase of cdma2000 with one channel, 5 MHz bandwidth and code rate 3.6864 Mcps:

$$P_{e(cdma2000)} = \frac{1}{\pi}\int_0^{\frac{\pi}{2}}\prod_{j=1}^{J}\left(\frac{m\sin^2\theta}{He^{-\sigma(L-1)}+m\sin^2\theta}\right)^m d\theta \tag{22}$$

IV. Simulation and Result

Simulation for average BER is considered (21) and (22) with the system performance impact from the parameters changing with voice (8kbps) and WWW service (16kbps) These parameters is E_b/N_0, the number of user (K), signal attenuation rate (δ), the transmitted power control (V), the number of user in adjacent cell (M), voice activity factor (λ), number of signal path (L), Number of finger (J) and number of antenna (ξ), as shown in table 1.

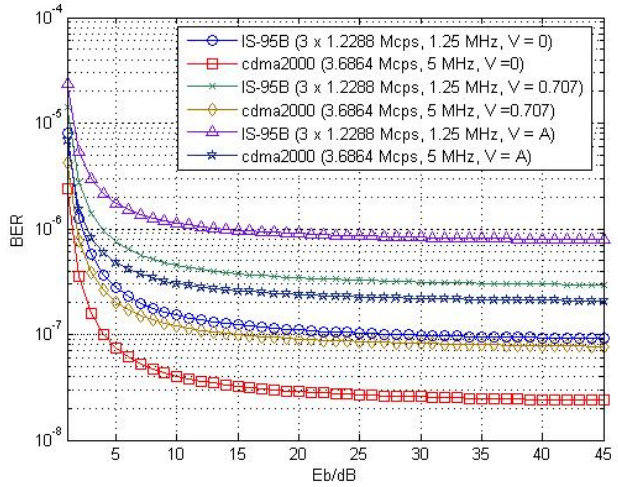

Figure 6. BER comparison between 3 x IS-95B and CDMA2000 for J=10, M=18, data rate 8 kbps (voice) and number of antenna 1 and 2 (perfect and imperfect power control)

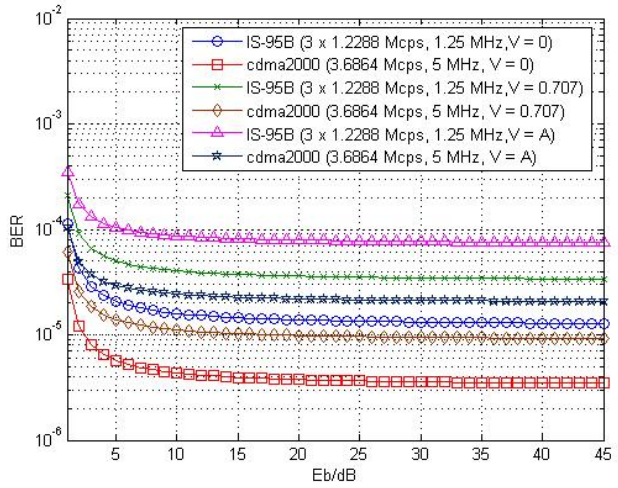

Figure 7. BER comparison between 3 x IS-95B and CDMA2000 for J=10, M=18, data rate 16 kbps and number of antenna 1 and 2 (perfect and imperfect power control)

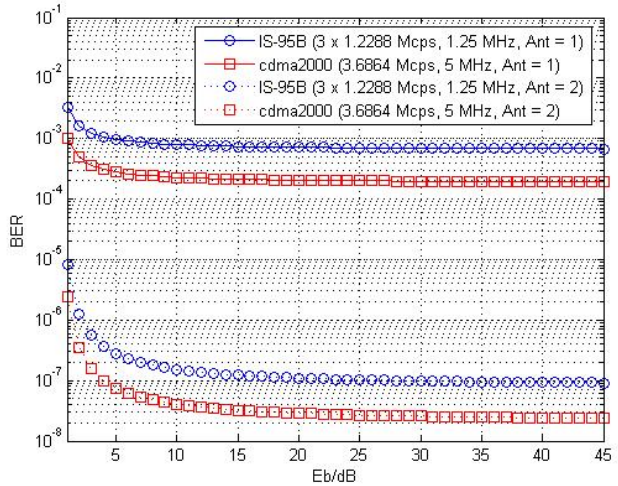

Figure 7. BER comparison between 3 x IS-95B and CDMA2000 for J=10, M=18, data rate 16 kbps and number of antenna 1 and 2 (perfect power control)

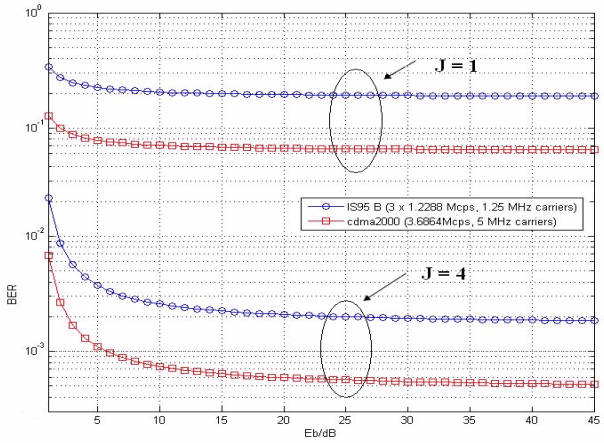

Figure 8. BER comparison between 3 x IS-95B and CDMA2000 for J=1 and 4

TABLE II
SIMULATION PARAMETER

Paremeter	IS-95B (f1)	IS-95B (f2)	IS-95B (f3)	CDMA 2000
Number of signal path	10	10	10	10
Data input	8,16kpbs	8,16kpbs	8,16kpbs	8,16kpbs
Voice activity	3/8	3/8	3/8	3/8
Maximum weighting	1	1	1	1

Result of simulation shows in figure 5, 6, 7 and 8. Figure 5 and 6 shows performance of perfect power control is better than imperfect power control. Performance of CDMA 2000 is better than 3xIS-95B in the same band with and data rate will increased, the performance will be decreased.

Figure 7 and 8 shows performance can be improve by increase number of antenna and number of finger.

V. CONCLUSION

The analysis of average BER on both systems shows the difference by using 5 MHz frequency bandwidth. Performance increases when compared to IS-95B, which uses 3 channels. Because of the interference between adjacent channel in IS-95B, in practice the system must be loose some bandwidth to reduce the adjacent interference.

Anyway the system investment can be reduced by improving the IS-95B performance close to CDMA2000 since it is the existing system. The performance can be compensation with the increasing of the number of finger and the number of antenna which leads to the adjacent interference reduction.

***Abstract*—This paper reports the measurement techniques of transmissions from ultra wideband (UWB) devices summarized in ITU-R task group (TG) 1/8 to study the compatibility between ultra-wideband (UWB) devices and radiocommunication services. The author has published a paper with the similar title in September 2005 [1] based on the discussion of TG 1/8 until October 2004. As TG 1/8 has concluded the discussion and compiled the recommendation in October 2005, this paper provides the updated information on the background idea behind the measurement methods, as ITU-R recommendation does not contain any citations to the references, nor any "educational" description of the theoretical background.**

I. Introduction

To avoid the harmful interference of the ultra wideband (UWB) transmissions to the existing radio services, the transmission limit of the UWB devices shall be restricted. It is essential to define the transmission level of the UWB devices by the measurements. However, it is not so straightforward to measure the transmission characteristics of the UWB devices.

In the International Telecommunication Union Radiocommunication sector (ITU-R), task group (TG) 1/8 had been established in July 2002 to study the compatibility between ultra-wideband devices and radiocommunication services. TG 1/8 had been divided into four working groups (WGs), i.e. characteristics in WG 1, compatibility in WG 2, spectrum management framework in WG 3, and measurements in WG 4. The standard measurement techniques of emissions from UWB devices had been discussed in TG 1/8 WG 4.

The activity of TG 1/8 had been completed in October 2005 with four draft new recommendations (DNRs) and one draft new report submitted to study group (SG) 1 for spectrum management. After the approval of SG 1, member administrations (countries) have also approved these DNRs to be new recommendations (NRs) by letter ballot. Finally they are issued as NRs in May 2006 [2], [3], [4], [5].

This paper provides the update information to the previous paper [1] to describe the measurement techniques presented in the measurement recommendation [2]. Since ITU-R recommendation does not contain any citations to the references, nor any "educational" description of the theoretical background. Therefore, the paper provides the background idea behind the measurement methods, which is not available on the recommendation. To avoid the overlap, the changes from the previous paper [1] are more emphasized.

II. Philosophies of Measurements

Considering that the aim of the ITU-R recommendation is to provide the sufficient technical information to the administrations, it is not always necessary to provide the precise measurement method with tremendous cost and time. The regulatory or the compliance measurement procedure shall be simple enough to complete within a feasible period by using the off-the-shelf instruments. The measured value shall be reasonably meaningful from the view points of compatibility and/or coexistence with other radio systems, but it is not necessary that the measured value is completely identical to the real physical quantity.

III. Power Spectral Density

The UWB transmission is quantitatively evaluated by the power spectral density (PSD), of the power contained within a specified segment of spectrum, instead of the total power in the full frequency band. This is a reasonable criterion from the viewpoint of the impact of UWB transmission to other radiocommunication systems.

Three PSD values are used for different purposes; peak PSD, average PSD, and quasi-peak PSD.

Peak PSD mainly influences the RF front end of the receiver, e.g. the saturation of the low noise amplifier. Therefore, it is not necessary to evaluate the total peak power in the whole bandwidth, but the peak power within the sufficiently wide bandwidth that corresponds to the RF filter of the victim receiver. In the recommendation, the bandwidth of 50 MHz is used.

Average PSD is a measure of the interference to the victim system. To roughly estimate the effect of the interference, the interference signal power can be treated as the increase of the noise level.

Quasi-peak PSD is applicable in the frequency below 1000 MHz, which is a kind of weighted peak. This value is fully compatible with the unwanted emission [6].

Equivalent isotropic radiated power (EIRP) is used to evaluate the emission level. It is the product of the power supplied to the antenna and the antenna gain in a given direction relative to an isotropic antenna. EIRP is a direct measure of the emission, but it is a function of both direction and frequency, and it is rather difficult to find the maximum value.

IV. Spectral Emission Mask

The UWB transmission is spread over a very large frequency range and overlaps several frequency bands allocated to radio services. Therefore, it is a reasonable approach that the transmission level shall be restricted by the spectral transmission mask [4], just like the unwanted emission limit of unintentional emitters for electromagnetic compatibility (EMC). Although the emission limit itself is not the matter of the measurement, Appendix describes the conflicts of emission masks for communication and non-communication devices. Note that the mask value has the impact on the specification and the configuration of the instruments.

V. Frequency Domain vs Time Domain Measurement Approaches

Section 1.1 of recommendation [2] describes about two alternative approaches for the measurements.

One approach is the time domain measurement of the signal. The time domain data are transformed into the frequency domain data via the digital signal processing (DSP), such as the discrete Fourier transform (DFT). The second approach is a direct measurement of the UWB spectral characteristics in the frequency domain. There are equipment limitations that must be considered with respect to either of these measurement approaches.

The state-of-art single-end oscilloscope can measure a single-event waveform up to 20 GHz, while the quantization bits of A/D converter is limited to 8 bits. It is suitable for the peak PSD measurements with wider resolution bandwidth (RBW) that can not be achieved by the spectrum analyzer. Contrary, the relatively narrow dynamic range prevents the measurements of the low level emission outside the UWB bandwidth.

The IF-swept spectrum analyzers are typically designed to measure conventional narrow-band signals. The IF bandwidth of the spectrum analyzer is significantly smaller than the bandwidth of the UWB waveform, and is even smaller than the 50 MHz reference bandwidth for the peak power measurement. It is necessary to convert the narrow band measurement results into the estimate of the power within wider RBW. In addition, conventional spectrum analyzer is not so sensitive as to detect UWB signals at the very low emission limits applicable in specific frequency bands.

As is mentioned in Section 1.10 of the recommendation [2], the noise level of the spectrum analyzer is about -47 dBm/MHz at 1 GHz. Therefore, it is necessary to use a low noise amplifier (LNA) together with the appropriate RF preselection filter for the low level transmission measurement.

VI. Measurement Conditions

Section 1.4 of the recommendation [2] describes the measurement environments. A semi-anechoic chamber is suggested below 1000 MHz, while an anechoic chamber is recommended for above 1000 MHz.

As to the rotation of the equipment under test, the angular resolution of the measurement is not quantitatively specified but simply suggested as to "take sufficient measurements both in azimuth and elevation to ensure the maximum value has been recorded."

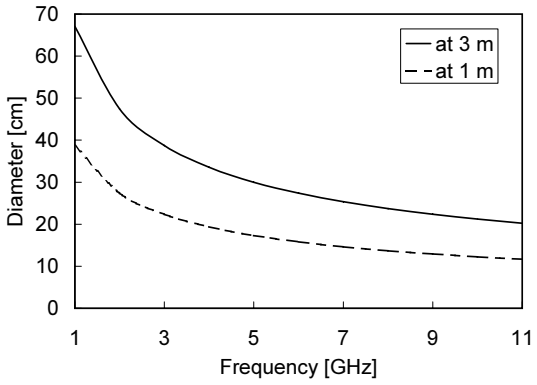

Fig. 1. Maximum UWB device size to satisfy far field condition.

Section 1.7 of the recommendation [2] describes the measurement distance. The distance of 3 m is normally recommended. It can be decreased to 1 m or less in case the signal is too weak, with taking care of the far field condition.

Figure 1 shows the maximun size (diameter) of the UWB device that satisfies the far field condition at 3 m and 1 m, which is derived by

$$r = \frac{2D^2}{\lambda}, \tag{1}$$

where r is the measurement distance, λ is the wavelength and D is the diameter of the sphere to enclose the device under test. For the high frequency, far field condition is more difficult to achieve in reality.

VII. Frequency Domain Measurements

Chapter 2 of the recommendation [2] describes the frequency domain measurements of PSD. First of all, the UWB bandwidth should be determined. Then, average and peak PSD measurements follow.

In the state-of-art IF-swept spectrum analyser, IF output is sampled at the constant frequency, e.g. 20 MHz. Within one frequency bin, the measurement is conducted during the period equal to the sweep time divided by the number of frequency bins in a sweep, to obtain the series of samples within a single frequency bin. The r.m.s. and peak detectors in the spectrum analyzer are digitally implemented to output the root-mean-square and the peak of the samples within the frequency bin for one sweep. The display function of max-hold trace mode is to trace the maximum values of all the frequency bins with respect to the multiple sweeps.

A. Determination of -10 dB bandwidth

Section 2.1 of the recommendation [2] describes the determination of -10 dB bandwidth. First, f_M is defined as the frequency with the maximum peak PSD. The spectrum analyser should be set up with 1 MHz resolution bandwidth

(RBW) and 1 MHz or greater video bandwidth (VBW), as well as with the max-hold trace mode. The lowest frequency below f_M and the highest frequency above f_M with the peak PSD 10 dB below the peak PSD at f_M are defined as f_L and f_H respectively. The UWB transmission is bounded by f_L and f_H, and the -10 dB bandwidth B_{-10} is defined as $f_H - f_L$.

B. Average PSD

Section 2.4 of the recommendation [2] describes the average PSD measurement.

Average PSD is measured by r.m.s. detector with the RBW of 1 MHz and the measurement period per frequency bin of 1 ms. In general, the maximum value of the average PSD tends to be smaller for impulsive signals with a low duty cycle when the measurement period becomes larger. Therefore, the measurement period is upper-bounded. Alternative measurements using zero span and power integration are also presented in the recommendation.

Moreover, the use of LNA and the radiometric measurement for the low level emissions are provided in sections 2.5 and 2.6, respectively.

C. Peak PSD

Section 2.7 of the recommendation [2] describes the peak PSD measurement.

The peak PSD of a UWB transmissions is defined as the peak power in a Gaussian filter with a bandwidth of 50 MHz. However, only the resolution bandwidths of 3 MHz or less can closely approximate the ideal Gaussian filter characteristics on the spectrum analysers. Therefore, the following scaling equation is used.

$$\mathrm{Limit}_{\mathrm{RBW}} = \mathrm{Limit}_{\mathrm{BW}} + 20\log_{10}\frac{\mathrm{RBW}}{\mathrm{BW}} \tag{2}$$

The measurement is made using a peak detector and max hold.

In fact, this equation is applicable for an impulsive signal, and it gives a conservative scaling of the peak PSD limit in general. When the signal appears to be noise-like, the complementary cumulative distribution function (CCDF) mode is used to test whether $10\log$ law can be applicable. If the CCDF falls within ± 2 dB error from the CCDF of a Rayleigh distribution in the range from 1 % to 99 %, the following scaling is applicable.

$$\mathrm{Limit}_{\mathrm{RBW}} = \mathrm{Limit}_{\mathrm{BW}} + 10\log_{10}\frac{\mathrm{RBW}}{\mathrm{BW}} \tag{3}$$

D. Conducted Measurements

Section 2.9 of the recommendation [2] describes the conducted measurements.

In case of the conducted measurement, the EIRP value is obtained by

$$\mathrm{e.i.r.p.}(f) = P(f) + G(f) \tag{4}$$

where $\mathrm{e.i.r.p.}(f)$ is the EIRP in dBm at the frequency f, $P(f)$ is the power in dBm measured at frequency f and at the antenna terminal, and $G(f)$ is the antenna gain in dBi measured at the frequency f in a given direction.

It is noted that the conducted measurement became only the measurement method approved in Japan. The major reason is described in Appendix.

VIII. Time Domain Measurements

Chapter 3 of the recommendation [2] describes the time domain measurements of PSD.

As is shown in Ref. [1], it is insufficient to use the oscilloscopes for the purpose to measure low emission levels due to the insufficient dynamic range. The time domain measurements by using oscilloscopes are only adequate to measure the highest emission limit. In particular, the peak PSD measurement with 50 MHz Gaussian filter is only possible in the time domain measurement.

Section 3.3 of the recommendation [2] presents the post processing of the time domain data. The complex antenna factor (CAF) of the measuring antenna is needed to reconstruct the electric field waveform from the antenna terminal voltage. In the frequency domain, the CAF $F_c(f)$, the complex electric field $E(f)$ and the terminal voltage with the matched impedance $V_0(f)$ are related as

$$F_c(f) = \frac{E(f)}{V_0(f)}. \tag{5}$$

By using discrete Fourier transform and its inverse, the filtered electric field strength can be reconstructed from the measured terminal voltage. The detail is presented in Ref. [7].

Section 3.4 of the recommendation [2] presents an alternative apparatus for peak power measurement. It combines a spectrum analyser with an oscilloscope. The spectrum analyser is used as the frequency down-converter together with the IF filter. The spectrum analyser IF output is an input to the oscilloscope. The IF output of the spectrum analyser is wide but its center frequency is much lower than the original RF signal. Therefore, the requirement for the sampling frequency of the oscilloscope is much relaxed. The Gaussian filtering is performed with digital signal processing without any phase distortion that would result from an analogue RBW filter.

IX. Conclusion

This paper has described the measurement techniques of the UWB emission, based on the ITU-R recommendation on the UWB measurement [2] to provide the updated background idea behind the measurement methods, in addition to the preceding paper [1].

Acknowledgement

This paper describes the personal opinion of the author himself, and does not represent the opinion of any party including NICT, ITU-R, or Ministry of Internal Affairs and Communications Japan. However, the author thanks all the members in NICT UWB Institute, NICT UWB Consortium, and ITU-R TG 1/8 WG 4, for their helpful discussions, suggestions, debate and encouragement.

APPENDIX: CONFLICT OF INTENTIONAL AND UNINTENTIONAL EMISSION MASKS

When UWB devices are permitted in United States, the average spectral mask level in the main UWB band 3.1–10.6 GHz has been chosen as −41.3 dBm/MHz [8]. It is noted that this emission level includes everything, i.e. UWB transmission and other emission. In the author's personal opinion, it was a challenge toward the existing conflict between two international regulations.

Any intentional emission of the radio is regulated by ITU-R, while unintentional emission of the radio is regulated by CISPR (Comité International Spécial des Perturbations Radioélectriques; International Special Committee on Radio Interference). Specifically, the ITU-R recommendation of the impact of UWB devices on the existing radiocommunication systems [5] and the CISPR standard on the radio disturbance characteristics of the information technology equipments [9] are to be compared. In CISPR [9], the upper limit of the unintentional average emission level in 3–6 GHz is 54 dBμV/m at 3 m for the reference bandwidth of 1 MHz, which is equal to −41.3 dBm/MHz e.i.r.p. although the recommended measurement method is slightly different from ITU-R [2]. However, much lower values are recommended for the transmission of UWB signal in the ITU-R recommendation [5]. Although ITU-R and CISPR have some contacts to each other, these two bodies decide the upper limits almost independently. As ITU-R should consider all the individual existing radiocommunication services, more conservative mask levels should be applied to the intentional emission.

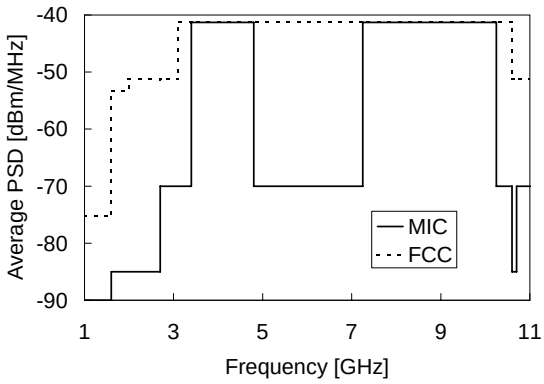

Fig. 2. Emission masks of average PSD of FCC indoor and MIC.

Considering the attitude of FCC that the regulation about the spectrum is basically the domestic matter as far as there is no interference outside US, it seems to the author rather natural that FCC chose more aggressive value, since the communication and non-communication signals can not be distinct with respect to the interference.

In Japan, however, the existing users of the radiocommunication services were not satisfied with the UWB devices to transmit up to the non-intentional emission limit. Ministry of Internal Affairs and Communications (MIC) finally approved the UWB systems in the Ordinance for Regulating Radio Equipment in August 2006 [10]. The spectral mask for the average PSD is presented in Fig. 2 in comparison with FCC indoor mask. For the compliance with the existing Japanese radio regulation, the UWB device should not be measured separately but should be integrated into the equipment such as PC. In case, PC itself may emit the power up to the limit of unintentional emission, and it is very difficult for the whole equipment to satisfy the UWB regulation. Therefore, the conducted measurement is needed to measure only the intentional transmission from the UWB device. In addition, it is not so easy to find the direction and frequency of the maximum transmission in the radiated measurement, since the antenna radiation pattern changes according to the frequency, and the measurement need tremendous time. They are the major reasons why the conducted measurement is only considered in Japan.

***Abstract*— This paper present the transmission gain of UWB system based on the extended Friis' transmission formula. The template waveform is considered at the receiver side to maximize the SNR for evaluation. An experimental evaluation of the antenna transfer function needs the three types of broadband antennas. The technique gives very accurate results and is very useful for design and evaluation of UWB impulse radio transmission systems, especially for the evaluation of waveform distortion effects.**

Keywords: **UWB, link budget, transmission gain, Friis' transmission formula**

I. INTRODUCTION

The propagation channel is in line of sight (LOS), Friis' transmission formula cannot be directly applied to the UWB radio as the bandwidth of the pulse is extremely wide. Furthermore, simple comparison between waveforms of transmitter and receiver is not significant because of the distortion of the waveform caused by the frequency response of the antenna.

In this paper, we discuss the free space link budget and transmission gain evaluation scheme for UWB impulse radio systems. This scheme is based on the Friis' transmission formula, adapted for UWB, in the sense that we would like to derive the equivalent antenna gain for UWB impulse radio systems. The transmission waveform and the receiver template waveform are keys for the extension of the Friis' transmission formula to UWB transmission signal.

II. THOERY

In this study, we focus on the link budget evaluation for UWB impulse radio system in free space.

A. Extension of Friis' Transmission Formula for UWB transmission System

The Friis' transmission formula [1] has been widely used, and can be applied to the calculation of these LOS channels.

$$G_{\text{Friis}}(f) = \frac{P_{\text{r}}(f)}{P_{\text{t}}(f)} = G_{\text{f}}(f)G_{\text{r}}(f)G_{\text{t}}(f), \tag{1}$$

where G_{r} and G_{t} are Rx and Tx antenna gain,

$$G_{\text{f}}(f) = \left(\frac{\lambda}{4\pi d}\right)^2 \tag{2}$$

is the free space propagation gain (less than unity in practice), $\lambda = \dfrac{c}{f}$ is the wavelength, c is the velocity of the light, f is the operating frequency, and d is the separation between transmitter and receiver antennas.

It is noted, however, that Eq. (1) is satisfied only at some certain frequency, and is not directly applicable to UWB systems. The Friis' transmission formula shall be extended to take into account the transmission signal waveform and its distortion as well [2].

Input signal $v_{\text{i}}(t)$ at the transmitter port is expressed as the convolution of an impulse input and the pulse shaping filter $h_{\text{i}}(t)$ as

$$v_{\text{i}}(t) = E_{\text{i}}\delta(t) * h_{\text{i}}(t), \tag{3}$$

where

$$\int_{-\infty}^{\infty} h_{\text{i}}^2(t)\mathrm{d}t = \int_{-\infty}^{\infty} |H_{\text{i}}(f)|^2 \,\mathrm{d}f = 1. \tag{4}$$

Friis' formula is extended taking into account the transmission waveform as

$$H_{\text{e-Friis}}(f) = \frac{V_{\text{r}}(f)}{E_{\text{i}}} = H_{\text{f}}H_{\text{i}}\mathbf{H}_{\text{r}} \cdot \mathbf{H}_{\text{t}}, \tag{5}$$

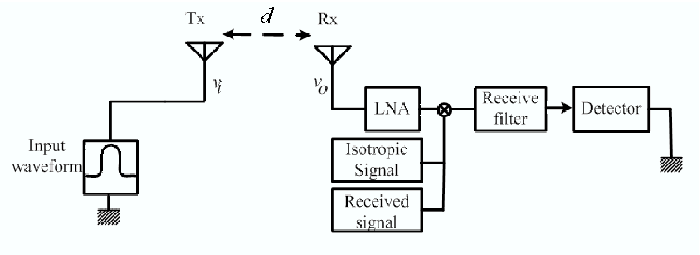

Fig. 1. Block diagram of transmission system for the extension of Friis' transmission formula to treat UWB signal.

where

$$\begin{aligned}\mathbf{H}_a &= \mathbf{H}_a(\theta_a,\ \varphi_a,\ f) \\ &= \hat{\boldsymbol{\theta}}_a H_{a\theta}(\theta_a,\ \varphi_a,\ f) + \hat{\boldsymbol{\varphi}}_a H_{a\varphi}(\theta_a,\ \varphi_a,\ f) \quad (6) \\ a &= \text{r } \textit{or } \text{t},\end{aligned}$$

is a complex transfer function vector of the antenna relative to the isotropic antenna,

$$H_{\mathrm{f}} = \frac{\lambda}{4\pi d}\exp(-\mathrm{j}kd), \quad (7)$$

is the free space transfer function where

$$k = \frac{2\pi}{\lambda}, \quad (8)$$

is the propagation constant.

B. Correlation Receiver

Let us consider a correlation receiver shown in Fig. 1. The output SNR is dependent on the choice of the template waveform. The correlator output $v_{\mathrm{o}}(\tau)$ is therefore expressed as

$$v_{\mathrm{o}}(\tau) = \int_{-\infty}^{\infty} v_{\mathrm{r}}(t) h_{\mathrm{w}}(t-\tau)\mathrm{d}t, \quad (9)$$

where $v_{\mathrm{r}}(t)$ is the receiver input waveform which is inverse Fourier transform, and $h_{\mathrm{w}}(t)$ is the template waveform. τ corresponds to the timing of the template waveform, and the optimum timing τ_{o} is chosen as

$$\tau_{\mathrm{o}} = \arg\max_{\tau} v_{\mathrm{o}}(\tau). \quad (10)$$

Hereafter $h_{\mathrm{w}}(t)$ is normalized as

$$\int_{-\infty}^{\infty} |h_{\mathrm{w}}(t)|^2 \mathrm{d}t = 2B, \quad (11)$$

where B is the signal bandwidth, so that the output noise power is constant as $N_0 B$, where $\frac{N_{\mathrm{o}}}{2}$ is power spectral density of AWGN.

Under the constraint of Eq. (11), $h_{\mathrm{wm}}(t)$ maximizes $v_{\mathrm{o}}(\tau_{\mathrm{o}})$ when $h_{\mathrm{wm}}(t)$ is a time-reversed and scaled version of $v_{\mathrm{r}}(t)$, i.e.

$$h_{\mathrm{wm}}(t) = \frac{\sqrt{2B}\, v_{\mathrm{r}}(\tau_{\mathrm{o}} - t)}{\sqrt{\int_{-\infty}^{\infty} |v_{\mathrm{r}}(t)|^2 \mathrm{d}t}}, \quad (12)$$

where τ_{o} is usually chosen so that $h_{\mathrm{wm}}(t) = 0$ for $t < 0$ to satisfy the causality. $h_{\mathrm{wm}}(t)$ is called the optimum template waveform hereafter. It is noted that the link budget evaluation is identical to that in Ref. [5] when $h_{\mathrm{wm}}(t)$ is used as the receiver template.

C. Isotropic Correlation Receiver

It is obvious from Eq. (12) that the optimum template waveform is not the simple time-reversed version of the transmitter waveform, but the channel characteristics including the antennas and the free space propagation. Therefore, it is not always feasible to adapt the template waveform to the angular-dependent antenna characteristics, since the waveform shall be generated at the clock rate of tens of gigahertz. Therefore, we consider a canonical template waveform $h_{\mathrm{wc}}(t)$. In this paper we have chosen $h_{\mathrm{wc}}(t)$ that is optimum for the isotropic and the constant gain antennas, i.e.

$$h_{\mathrm{wc}}(t) = \frac{\sqrt{2B}\, v_{\text{r-iso}}(\tau_{\mathrm{o}} - t)}{\sqrt{\int_{-\infty}^{\infty} |v_{\text{r-iso}}(t)|^2 \mathrm{d}t}}, \quad (13)$$

where

$$v_{\text{r-iso}}(t) = \int_{-\infty}^{\infty} H_{\mathrm{f}}(f) V_{\mathrm{t}}(f) \exp(\mathrm{j}2\pi f t)\mathrm{d}f \quad (14)$$

is the receiver input voltage for isotropic antenna including. The difference between the optimum and the isotropic templates indicates quantitatively the distortion of the waveform.

III. UWB Antenna Transfer Function Measurements

A. UWB waveform Transmission

The effect of the waveform distortion is more obvious when the bandwidth is wider. We considered the impulse

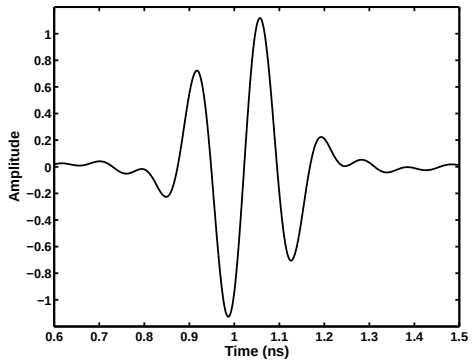

Fig. 2. The transmission waveform of UWB signal.

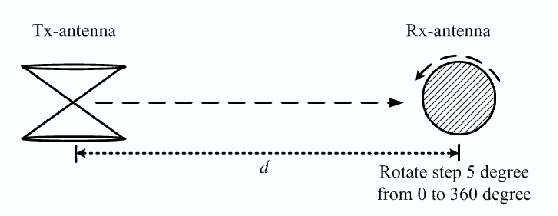

Fig. 3. Top view antenna setting.

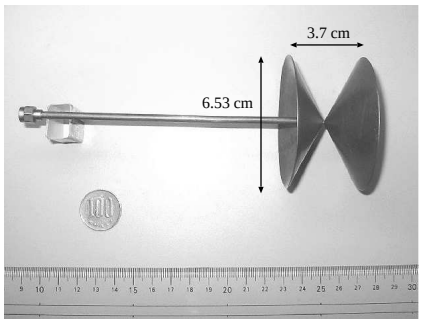

Fig. 4. Biconical antenna structure.

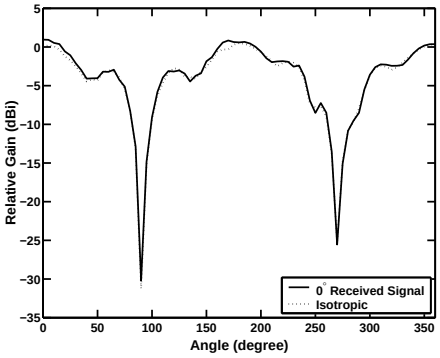

Fig. 5. Normalized UWB transmission gain for biconical–biconical link.

radio signal that fully covers the FCC band [4], i.e., $3.1 \sim 10.6$ GHz. The center frequency and the bandwidth were therefore set to be $f_0 = 6.85$ GHz and $f_\mathrm{b} = 7.5$ GHz, respectively. The transmit waveform assumed in the simulation was a single ASK pulse with the carrier frequency f_0. To satisfy the bandwidth requirement of f_b, the pulse length was set to be $\frac{2}{f_\mathrm{b}}$. Then the signal was band-limited by a Nyquist roll-off filter with roll-off factor $\alpha = 0$ (rectangular window) and passband $\left(f_0 - \frac{f_\mathrm{b}}{2},\ f_0 + \frac{f_\mathrm{b}}{2}\right)$. Figure 2 shows the transmit pulse waveform. The transmission process of the pulse waveform is simulated based on the measured transfer function of the antenna.

B. Experimental Setup and Measurement Model

The VNA was operated in the response measurement mode, where Port-1 was the transmitter port (Tx) and Port-2 was the receiver port (Rx), respectively. Biconical antennas with the maximum diameter of 65.3 mm and the length of 37 mm are used both as the standard antennas and as AUT. The measurement was done in the anechoic chamber. Both Tx and Rx antennas were fixed at the height of 1.75 m and separated at a distance of 4 m.

Figure 3 shows the orientations of the S_{21}, transfer function measurement for Tx and Rx antennas. The Tx antenna is fixed at pointing angle 0° and the Rx antenna is rotated from pointing angle 0° to 360° with each step at 5°.

IV. Experiment Results

In this section, standard broadband antennas and deployable antennas are used in the measurement for the link budget evaluation.

USA suggested the use of a biconical antenna, and log-periodic antenna for the frequency ranges of $30 - 200$ MHz, $200 - 960$ MHz, and $0.96 - 18$ GHz, respectively, for the compliance test of UWB transmitters [6]. We chose these two kinds of antennas, operating in the same frequency range.

1) Biconical Antenna: First, the same biconical antennas were used at both Tx and Rx sides. Figure 5 shows the normalized UWB transmission gain as a function of antenna pointing angle in E-plane. Well-known 8-shaped patterns were obtained. Two template waveforms were used for comparison, and the difference was rather small. The phase center of the biconical antenna is the feed point and it has theoretically the frequency independent gain at the broadside direction, and that is why the waveform distortion effect is small compared with the isotropic template.

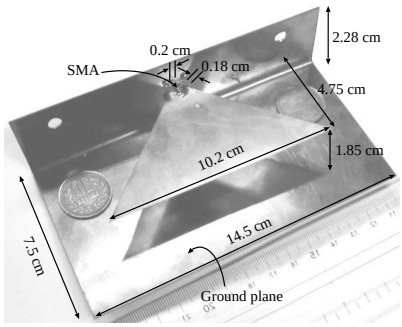

Fig. 6. Trapezoidal antenna with L-shaped ground plane.

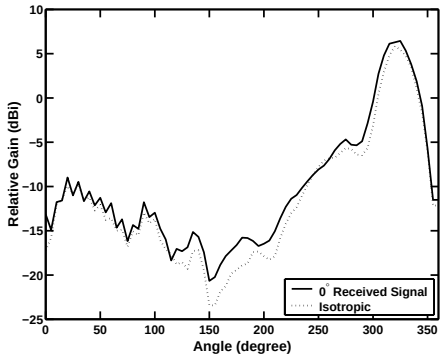

Fig. 7. Normalized UWB transmission gain for biconical–trapezoidal link.

2) Trapezoidal Antenna: A trapezoidal antenna with the L-shaped ground plane has been introduced by Duzdar and Kompa [7] and was later modified by Eskelinen [3]. We have chosen this antenna just for the ease of the fabrication The structure and dimensions of the antenna is shown in Fig. 6. The element shape itself is similar to that of a bow-tie antenna, but the L-shaped ground plane is parallel to the trapezoidal element to achieve the unidirectional characteristics.

Figure 7 shows the normalized UWB transmission gain pattern for biconical–trapezoidal link in E-plane. Note that 0° and 270° are the top and the broadside of the antenna, respectively. The peak is found at 320°. Therefore, the peak is elevated from the broadside of the antenna toward the top. The gain is relatively high, and the difference between two templates is small. As Refs.[1] consider the waveform transmission applications, the waveform distortion seems to be small.

V. Conclusion

This presented the evaluation scheme for UWB transmission gain, which includes the transmit waveform, the antennas, free space propagation, and the receiver correlator template. By using the definition, we have evaluated two types of broadband antennas. The performance can be evaluated only by the UWB transmission gain.

Abstract - This paper describes a wave iterative method (WIM) which has been specifically analyzed a planar source. Unlike traditional full wave analysis simulators which compute and display the overall wave in space and time domain, this method visualizes the scattering waves of time domain in the conductor, dielectric, and source meshes. The source mesh of wave iterative method, a square shape, is a planar excitation source. Based on an iterative formulation, the novel quasi-network characteristics of planar source is found and analyzed. The wave iterative method needs to modify by using quasi-network for the accuracy and efficiency simulation.

Keywords : Wave iterative method, Quasi-network, Planar source

I. INTRODUCTION

In the microwave circuit analysis and design, certain electromagnetic analysis method presents the simulated circuit parameters. The transmission line matrix method (TLM) is usually defined in the time domain [1]. This TLM method visualizes the scattering and spreading of the individual voltage impulses in a TLM mesh. The finite difference time domain (FDTD) is a kind of efficient methods of computational electromagnetics [2]. Recently, the iterative methods are used more extensively in solving electromagnetic problems. These methods are due to the augmentation of the computational capacities and to the simplicity of the formulation [4-5]. Already successfully tested in some simple, the wave concept iterative procedure (WCIP) has shown the great potential of development in solving electromagnetic problems [6-7].

An efficient wave iterative method (WIM) has been developed from the wave concept iterative procedure which has been specifically designed as an educational simulation tool. The formulation of the iterative method is based on the incident and reflected wave concept which propagate the alternating between the spectrum domain (modes) and the time domain (pixels). In the electromagnetic scattering on the pixel area, the boundary conditions are presented in several sub-domains: the metal, the dielectric, and the planar source. This paper presents a study and analysis of the effect of planar source involved in the quasi-network model which is added to the iterative process.

II. THEORY

The wave iterative method (WIM) is a numerical method used for the study of electromagnetic problems. The principle of this method is the concept of scattering wave propagation. The propagation of the incident wave ($\vec{A}$) and the reflected wave ($\vec{B}$) in the planar circuit can be shown in the fig.1.

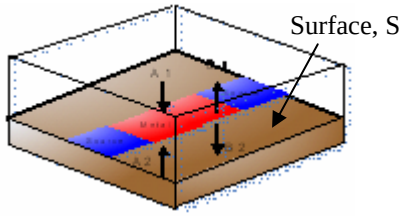

Fig. 1 Scattering wave of planar circuit

Considering the surface S to be a transverse section, the waves $\vec{A}$ and $\vec{B}$ are defined by (1)-(2):

$$\vec{A} = \frac{1}{2\sqrt{Z_0}}(\vec{E} + Z_0\vec{H}) \qquad (1)$$

$$\vec{B} = \frac{1}{2\sqrt{Z_0}}(\vec{E} - Z_0\vec{H}) \qquad (2)$$

when $\vec{E}$ and $\vec{H}$ are the tangent electric and magnetic field and Z_0 is the intrinsic impedance.

A.Quasi-Network of planar source

The planar source is the electromagnetic source which presents in the square pixel, shown in the fig.2.

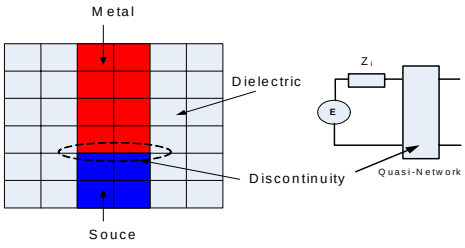

Fig. 2 Quasi-network of planar source

Appropriate equivalent circuits of the sub-domain of planar source represent the electric tangential field ($\vec{E}$) and source internal impedance (Z_i). The discontinuity between the planar source and the microstrip line presents a quasi-network which consists of a capacitor, inductor, and transformer, as shown in the fig. 3.

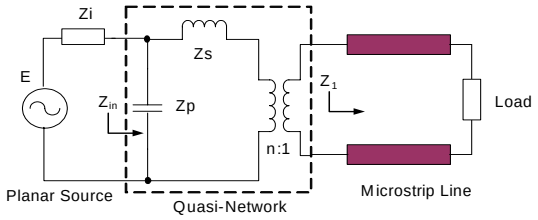

Fig. 3 Equivalent circuit of planar circuit

The ABCD parameter of a quasi-network is described by (3):

$$\begin{bmatrix} V_1 \\ I_1 \end{bmatrix} = \begin{bmatrix} n & \frac{Z_S}{n} \\ \frac{n}{Z_p} & \frac{Z_S+Z_p}{nZ_p} \end{bmatrix} \begin{bmatrix} V_2 \\ -I_2 \end{bmatrix} \quad (3)$$

and the Z parameter can be expressed as (4):

$$\begin{bmatrix} V_1 \\ V_2 \end{bmatrix} = \begin{bmatrix} Z_p & \frac{Z_p}{n} \\ \frac{Z_p}{n} & \frac{Z_s+Z_p}{n^2} \end{bmatrix} \begin{bmatrix} I_1 \\ I_2 \end{bmatrix} \quad (4)$$

From fig.3, the input impedance of planar circuit is written as (5):

$$Z_{in} = \frac{V_1}{I_1} = Z_p - \frac{Z_p^2}{n^2 Z_1 + Z_S + Z_p} \quad (5)$$

when Z_p is the parallel impedance of capacitor; Z_S is the series impedance of inductor; n is the ratio of transformer parameter; and Z_1 is the input impedance of microstrip line (without quasi-network) which is described by (6)-(7):

$$Z_{1(sc)} = jZ_0 \tan(\beta L) \quad \text{for Short Circuit} \quad (6)$$

$$Z_{1(oc)} = -jZ_0 \cot(\beta L) \quad \text{for Open Circuit} \quad (7)$$

The equivalent circuit of two ports network of the planar circuit can shows in the fig. 4.

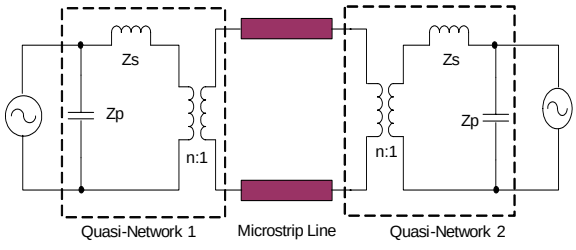

Fig. 4 Equivalent circuit of two port network

In the port 2, the ABCD parameter of a quasi-network is described by (8): Z_p

$$\begin{bmatrix} V_1 \\ I_1 \end{bmatrix} = \begin{bmatrix} \frac{1}{n}+\frac{Z_S}{nZ_p} & \frac{Z_S}{n} \\ \frac{n}{Z_p} & n \end{bmatrix} \begin{bmatrix} V_2 \\ -I_2 \end{bmatrix} \quad (8)$$

Fig.4 shows a structure composed of cascade ABCD networks of planar circuit; quasi-network 1, microstrip line and quasi-network 2. From equation (3) and (8), we represent the relation of ABCD parameter of the microstrip line as:

$$[ABCD_{Line}] = [ABCD_1]^{-1} \times [ABCD_{total}] \times [ABCD_2]^{-1} \quad (9)$$

B. Wave Iterative Method (WIM)

The wave iterative method is mainly a result of the building an iterative scheme that avoids the inversion of the integral operator to solve the boundary conditions problem owing to its waves based formulation [6]. On the printed surfaces, the boundary conditions are expressed in terms of waves rather than in terms of tangential fields. The whole printed surface is discredited by pixel-like functions. The scheme of the successive iterations is then given by

$$B = \hat{S}A + B_0 \quad in\ the\ pixel\ domain \quad (10)$$
$$A = \hat{\Gamma}B \quad in\ the\ mode\ domain$$

The toggling between the pixel and the mode representation of the waves A and B is ensured by a Fast Fourier Transform (FFT).

The diffraction operator ($\hat{S}$) of boundaries defines a built in the sub-domains; metal (M), dielectric (D) and source (S) area. The $\hat{S}$ operator can be written as (11):

$$\hat{S} = \begin{bmatrix} -M + \frac{(1-n^2)D}{1+n^2} + \frac{(-1+n_1-n_2)S}{1+n_1+n_2} & M + \frac{(2n)D}{1+n^2} + \frac{(2m)S}{1+n_1+n_2} \\ M + \frac{(2n)D}{1+n^2} + \frac{(2m)D}{1+n_1+n_2} & -M + \frac{(n^2-1)D}{1+n^2} + \frac{(-1-n_1+n_2)S}{1+n_1+n_2} \end{bmatrix} \quad (11)$$

when $n = \sqrt{\frac{Z_{01}}{Z_{02}}}$, $m = \frac{Z_0}{\sqrt{Z_{01}Z_{02}}}$, $n_1 = \sqrt{\frac{Z_0}{Z_{01}}}$, $n_2 = \sqrt{\frac{Z_0}{Z_{02}}}$ and 1, 2 are an order of layer.

Then, the iterative procedure rests on the balance conditions between the diffracted waves by the printed surfaces and the reflected waves by the circuit environment: substrate and enclosure. The advantage of wave iterative method is preserved by using a reflection operator ($\hat{\Gamma}$) defined in the spectral domain (TE and TM mode) from the admittance operator (Y_{mn}) as:

$$\hat{\Gamma} = \sum_{mn} |f_{mn}\rangle \Gamma_{mn}^{TE/TM} \langle f_{mn}| \quad (12)$$

where $Y_{mn}^{TE/TM}$ are the eigen values of the admittance operator, and

$$\Gamma_{mn}^{TE/TM} = \frac{Y_0 - Y_{mn}^{TE/TM}}{Y_0 - Y_{mn}^{TE/TM}} \quad (13)$$

when $Y_{mn}^{TE} = \frac{\gamma_{m,n}}{j\omega\mu}$, $Y_{mn}^{TM} = \frac{j\omega\varepsilon}{\gamma_{m,n}}$

The relation of the parameters Z and Y has the expression in the terms of the electric and magnetic filed as:

$$[Z]=[Y]^{-1}=\begin{bmatrix} \sum_{x,y}\left(\frac{E_{x,y(1)}}{H_{x,y(1)}}\right) & \sum_{x,y}\left(\frac{E_{x,y(1)}}{H_{x,y(2)}}\right) \\ \sum_{x,y}\left(\frac{E_{x,y(2)}}{H_{x,y(1)}}\right) & \sum_{x,y}\left(\frac{E_{x,y(2)}}{H_{x,y(2)}}\right) \end{bmatrix}_{Source} \quad (14)$$

The S parameter is defined as:

$$[S]=[Z-I][Z+I]^{-1} \quad (15)$$

III. QUASI-NETWORK PARAMETERS ANALYSIS

Fig.5 shows a microstrip structure. We can thus build an equivalent circuit for the discontinuity between the planar source and microstrip line (see in fig.3).

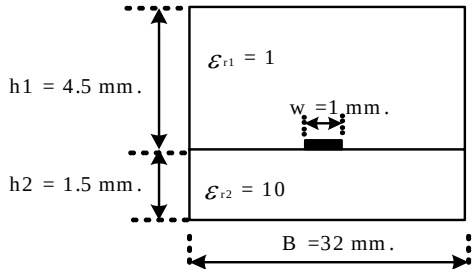

Fig. 5 Equivalent circuit of microstrip line

The analysis of the quasi-network by using WIM is done in 5 steps.

Step 1. Calculation of the input impedance (Z_{in}) of the planar circuit which is $\lambda/2$ of the length. From (5), when $Z_1=\infty$, thus we get:

$$Z_{in(\lambda/2)}=Z_p \quad (16)$$

Step 2. Calculation of the input impedance (Z_{in}) of the planar circuit which is $\lambda/4$ of the length. From (5), when $Z_1=0$, thus we get:

$$Z_{in(\lambda/4)}=\frac{Z_s Z_p}{Z_s+Z_p} \quad (17)$$

Step 3. Calculation of the input impedance (Z_{in}) of the planar circuit which is $3\lambda/8$ of the length. From (5), when $Z_1=-jZ_0\cot(\beta L)$, thus we get:

$$Z_{in}=Z_p-\frac{Z_p^2}{n^2 Z_1+Z_s+Z_p} \quad (18)$$

Step 4. From step (1) to (3), we calculated Z_p, Z_s and n of the quasi-network. The element values of the network at several frequencies can be found in table 1.

Table 1. Quasi-network parameters

f (GHz)	ε_{eff}	Z_c	Z_p	Z_s	n
6.950	7.276	57.98	-j157	+j32.93	0.939
4.730	6.981	64.41	-j215	+j24.65	0.958
3.615	6.721	59.71	-j218	+j18.74	1.013
1.850	6.417	59.47	-j493	+ j1.05	1.105
1.485	6.362	59.52	-j565	+ j8.44	1.031

Step 5. In the last step, we calculated the C_p, L_s for different frequency.

Table 2. Capacitor and inductor of quasi-network

f (GHz)	C (pF)	L(nH)	n	λ (mm)
6.950	0.15196	0.75406	0.939	16
4.730	0.15597	0.82930	0.958	24
3.615	0.15645	0.82498	1.013	32
1.850	0.17393	0.90324	1.105	64
1.485	0.18969	0.90477	1.031	80

For each frequency, the quasi-network elements of planar source are represented for the wave iterative method (WIM) simulation.

IV. NUMERICAL RESULTS

In this section, we present some examples of correction by using quasi-network of planar source for efficiency WIM simulation.

A. Input impedance of microstrip circuit

The input impedance of the open circuit-microstrip line is now studied in fig. 6. The circuit consists of the open-end line connected to a planar source.

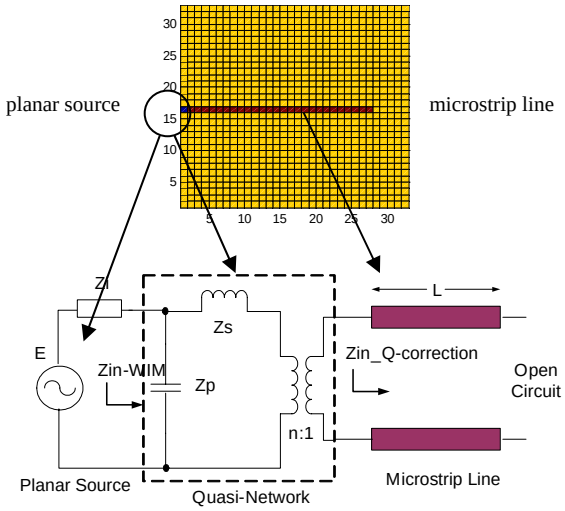

Fig. 6 Open circuit-microstrip line

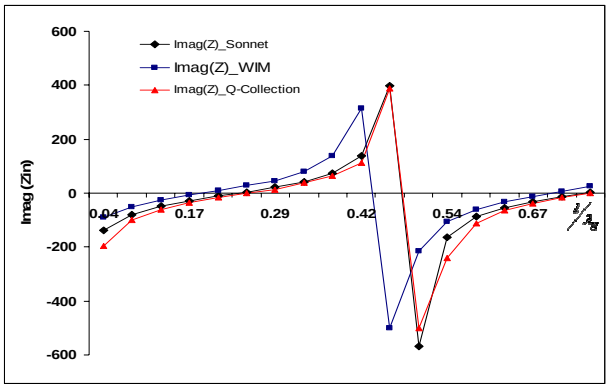

Fig. 7 Comparison of the input impedance obtained by WIM, WIM_(Q-correction) and SONNET Lite

In fig. 7, the input impedance of open circuit-microstrip line is plotted against normalized wavelength of line (l/λ_g). The trace of input impedance of the WIM shows the shift in resonance frequency. After to correct by using the quasi-network (Q-correction), the simulated results by the WIM (Q-correction) are compared with SONNET Lite, they are in very good agreement.

B. Microstrip circuit

The proposed approach is checked by considering the circuit given in fig. 8. The structure of the microstrip is shown in fig. 5, where $h_1 = 4.5$, $h_2 = 1.5$, w=1 mm, L=30 mm, $\varepsilon_{r1} = 1$ and $\varepsilon_{r2} = 10$.

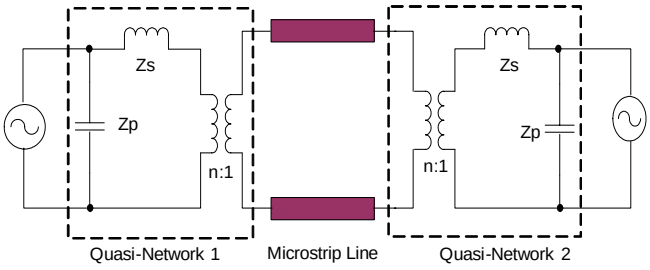

Fig. 8 Two ports network of microstrip line

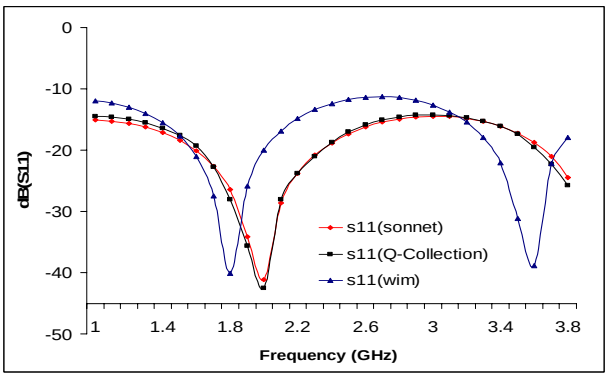
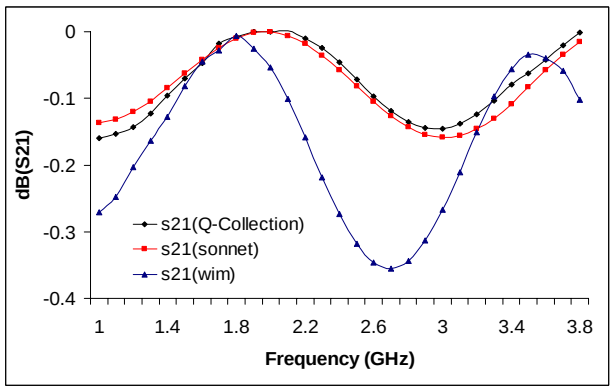


(a) dB (S11)



(b) dB (S21)

Fig. 9 Comparison of the S-parameter obtained by WIM, WIM_(Q-Collection) and SONNET Lite

Frequency variation of the dB(S11) and dB(S21) of the microstrip line is plotted in fig. 9. Better agreement between WIM (Q-correction) and SONNET Lite results can be obtained.

V. CONCLUSION

The efficiency and accuracy of WIM simulation has been presented to solving electromagnetic problems. In this case, the quasi-network of planar source has been characterized. The WIM is properly conceived to apply in microstrip line. The obtained results are very similar to the results of SONNET Lite simulation.

***Abstract*-The extended T-chart has been developed for solving problems associated with conjugately characteristic-impedance transmission lines (CCITLs) with *active* characteristic impedances. In this study, the constant circuit-node *Q* circles, denoted by Q_n, are constructed on the extended T-chart to assist in designing lossless matching networks for these CCITLs. The circles can be easily generated, and the procedures of obtaining these circles are discussed in detail.**

Keywords: CCITLs, active characteristic impedances, constant circuit-node *Q*, standard T-chart, extended T-chart.

I. INTRODUCTION

The T-chart has been developed for solving problems associated with conjugately characteristic-impedance transmission lines (CCITLs) with *passive* characteristic impedance ($\mathrm{Re}\{Z_0^{\pm}\} \geq 0$), where $Z_0^{\pm}$ are characteristic impedances of CCITLs [1]-[4]. A recent study has shown that CCITLs implemented by periodically loaded lossless lines can exhibit *active* characteristic impedances ($\mathrm{Re}\{Z_0^{\pm}\} < 0$) [5]. Interestingly, the associated magnitude of the voltage reflection coefficient for this case can be greater than or equal to unity for *passive* load terminations. In addition, the standard T-chart has recently been extended, called the extended T-chart, for CCITLs with active characteristic impedances [6].

Fig. 1 represents a lossless CCITL, terminated in a *passive* load impedance Z_L, possessing the propagation constants β^+ and β^-, with conjugate characteristic impedances Z_0^+ and Z_0^-, for propagation in the *forward* and *reverse* directions, respectively. For impedance matching problems shown in Fig. 2, a lossless network matches an arbitrary load impedance Z_L to a CCITL with active characteristic impedances. Previously, the generalized constant circuit-node *Q* circles on the standard T-chart were developed in [7]. In this paper, the generalized *Q* circles are extended to

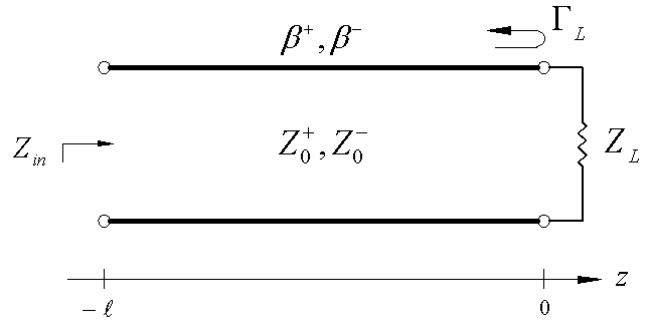

Figure 1. A lossless CCITL terminated in a passive load impedance Z_L.

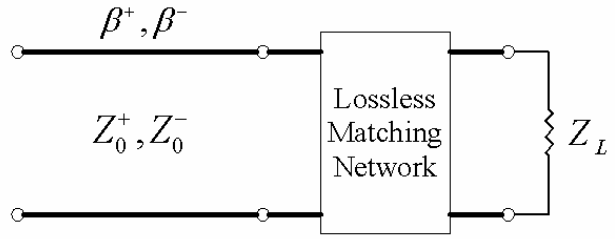

Figure 2. A lossless network matching an arbitrary load impedance Z_L to a CCITL with active characteristic impedances.

be plotted on the extended T-chart for problems associated with Fig. 2. At each node in the lossless matching network, the value of the circuit-node *Q*, denoted by Q_n, is determined by using the equivalent input impedance at the node. By definition, Q_n is the ratio of the magnitude of its reactance to its resistance at the node [8]. Therefore, several equivalent series input impedances can have the same Q_n. In this paper, equations of constant-Q_n contours will be shown and plotted on the extended T-chart for some phase angles ϕ of $Z_0^{\pm}$.

This paper is organized as follows. Section II presents the theory of CCITLs with active characteristic impedances in brief. The construction of the generalized constant-Q_n circles is illustrated in Section III. Section IV shows some numerical results. Finally, conclusions are provided in Section V.

II. THEORY OF CCITLS

This section provides the necessary background of CCITLs for constructing the constant-Q_n circles in the next section. CCITLs are lossless, and generally possess *different* characteristic impedances, Z_0^+ and Z_0^-, for propagation in the *forward* and *reverse* directions. It can be shown that the characteristic impedances $Z_0^{\pm}$ must be complex conjugate of one another [1], which can be expressed as

$$Z_0^+ = \left(Z_0^-\right)^*, \tag{1}$$

where the superscript * denotes the complex-conjugate symbol. For convenience, let us define $Z_0^{\pm}$ as

$$Z_0^{\pm} = |Z_0| e^{\mp j\phi}, \tag{2}$$

where $|Z_0|$ and ϕ are the absolute value and the argument of Z_0^-, respectively.

For *active* characteristic impedances, it is required that

$$\mathrm{Re}\left\{Z_0^{\pm}\right\} < 0. \tag{3}$$

Using (2) and (3), it is found that the argument ϕ must lie in the following range:

$$90^\circ < \phi \le 180^\circ \ \cup \ -180^\circ < \phi < -90^\circ. \tag{4}$$

The reflection coefficient at the load Γ_L for CCITLs is given by [1]

$$\Gamma_L = \frac{z_L z_0^- - 1}{z_L z_0^+ + 1}, \tag{5}$$

where z_L is the normalized load impedance and $z_0^{\pm}$ is the normalized characteristic impedances, where the normalized impedance z of an arbitrary impedance Z is defined as

$$z = \frac{Z}{|Z_0|}. \tag{6}$$

Using (2) and (6), $z_0^{\pm}$ is found to be

$$z_0^{\pm} = e^{\mp j\phi}. \tag{7}$$

It should be pointed out that when the argument ϕ lies within the range specified in (4), the magnitude of the reflection coefficient of the load $|\Gamma_L|$ is always greater than or equal to unity for a passive load termination. In the next section, the construction of the generalized constant-Q_n circles on the extended T-chart is illustrated.

III. Construction of the Generalized Constant-Q_n Circles on the Extended T-Chart

The generalized constant-Q_n circles on the extended T-chart are constructed by using the same concept as constructing the generalized constant-Q_n circles on the standard T-chart [7]. To derive equations for the generalized constant-Q_n circles, it is better to express the normalized impedance z in terms of its corresponding reflection coefficient Γ. Using (5), z can be expressed as

$$z = \frac{1+\Gamma}{z_0^- - z_0^+ \Gamma}. \tag{8}$$

For convenience in manipulation, let $\Gamma = \Gamma_r + j\Gamma_i$ and $z = r + jx$. Substituting Γ and z into (8) and using (7) yield the following equation:

$$r + jx = \frac{1+\Gamma_r + j\Gamma_i}{e^{j\phi} - e^{-j\phi}\left(\Gamma_r + j\Gamma_i\right)}. \tag{9}$$

In [8], Q_n is defined as

$$Q_n \equiv \frac{|x|}{r}. \tag{10}$$

Depending on the signs of x, (10) can be rearranged as follows:

$$\left[\Gamma_r - \frac{\sin\phi}{Q_n\cos\phi - \sin\phi}\right]^2 + \left[\Gamma_i + \frac{\cos\phi}{Q_n\cos\phi - \sin\phi}\right]^2 = \frac{\left(Q_n^2+1\right)\cos^2\phi}{\left(Q_n\cos\phi - \sin\phi\right)^2} \tag{11}$$

$$\left[\Gamma_r + \frac{\sin\phi}{Q_n\cos\phi + \sin\phi}\right]^2 + \left[\Gamma_i - \frac{\cos\phi}{Q_n\cos\phi + \sin\phi}\right]^2 = \frac{\left(Q_n^2+1\right)\cos^2\phi}{\left(Q_n\cos\phi + \sin\phi\right)^2}, \tag{12}$$

for $x > 0$ and $x < 0$, respectively. Thus, (11) and (12) are the equations of the generalized constant-Q_n circles in the case of CCITLs with active characteristic impedances. It should be pointed out that (11) and (12) are identical to those in the passive case [7]. Note that these two circle equations depend on the argument ϕ defined in (4) in a complicated fashion.

In the next section, numerical results of the generalized constant-Q_n circles on the extended T-chart will be illustrated.

IV. Numerical Results

Fig. 3 shows the plot of $Q_n = 5$ circles generated on the extended T-chart when $\phi = 180^\circ$. Note that the horizontal line across the extended T-chart represents the contour $x = 0$, the region below it corresponds to $x > 0$ and the region above it corresponds to $x < 0$. From Fig. 3, the constant-Q_n circles for $x > 0$ and $x < 0$ are symmetric about the contour $x = 0$. In addition, it is observed that these constant-Q_n circles intersect both open-circuited (OC) and the short-circuited (SC) locations.

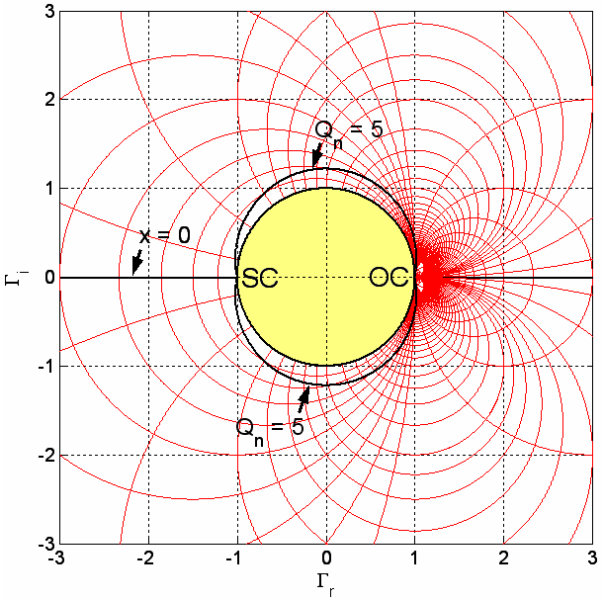

Figure 3. Plot of $Q_n = 5$ circles on the extended T-chart when $\phi = 180^\circ$.

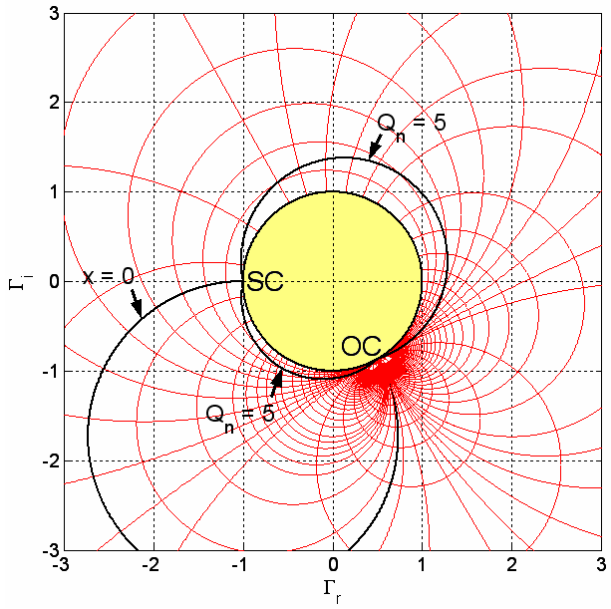

Figure 4. Plot of $Q_n = 5$ circles on the extended T-chart when $\phi = 150^\circ$.

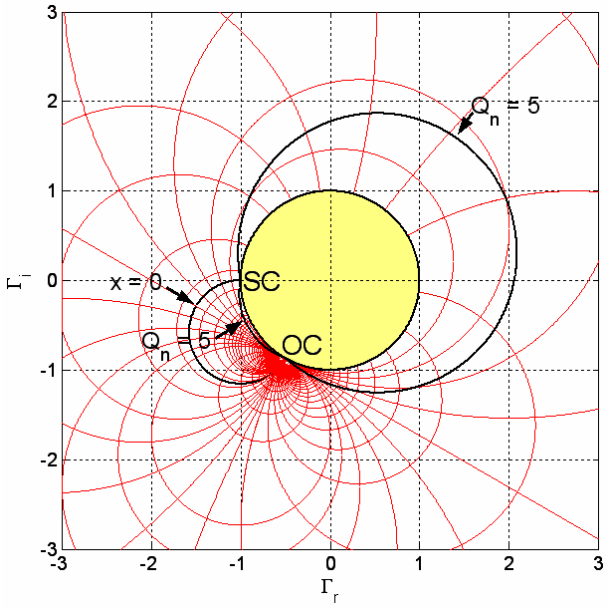

Figure 6. Plot of $Q_n = 5$ circles on the extended T-chart when $\phi = 120^\circ$.

As illustrated in Section III, the constant-Q_n circles depend on the argument ϕ. To illustrate this dependence graphically, let us consider several cases in the valid range of ϕ defined in (4). Fig. 4 shows the plot of $Q_n = 5$ circles on the extended T-chart when $\phi = 150^\circ$. Note that, outside the unit circle on the extended T-chart, the region outside the circle $x = 0$ corresponds to $x < 0$, and that inside the circle $x = 0$ corresponds to $x > 0$. The $Q_n = 5$ circle for $x < 0$ is larger than that for $x > 0$. In this case, the constant-Q_n circles are no longer symmetric about the contour $x = 0$.

Next, consider the case when $\phi = -150^\circ$. When the argument ϕ becomes negative, the center of the circle $x = 0$ is at the upper part of the extended T-chart. Fig. 5 illustrates the plot of $Q_n = 5$ circles on the extended T-chart when $\phi = -150^\circ$. Note that, outside the unit circle on the extended T-chart, the region outside the circle $x = 0$ corresponds to $x > 0$, and that inside the circle $x = 0$ corresponds to $x < 0$. Note that Figs. 4 and 5 look like the mirror image (about the horizontal axis) of each other.

Fig. 6 shows the plot of $Q_n = 5$ circles on the extended T-chart for $\phi = 120^\circ$. Note that the region $x > 0$ (inside the circle $x = 0$) becomes smaller as ϕ decreases from $\phi = 150^\circ$ (in Fig. 4) to $\phi = 120^\circ$. Fig. 7 illustrates the plot of $Q_n = 5$ circles on the extended T-chart when $\phi = -120^\circ$. Note that the region $x < 0$ becomes smaller as ϕ increases from $\phi = -150^\circ$ (in Fig. 5) to $\phi = -120^\circ$. Figs. 6 and 7 follow the same characteristics as in Figs. 4 and 5, respectively.

When $\phi \neq 180^\circ$, the contour $x = 0$ is not a horizontal line, and the constant-Q_n circles for $x > 0$ and $x < 0$ are not a symmetrical image of each other, as shown in Figs. 4 to 7. However, there are still some common properties that can be observed. For example, it can be seen that all constant-Q_n circles are intersected at the SC and OC points on the chart.

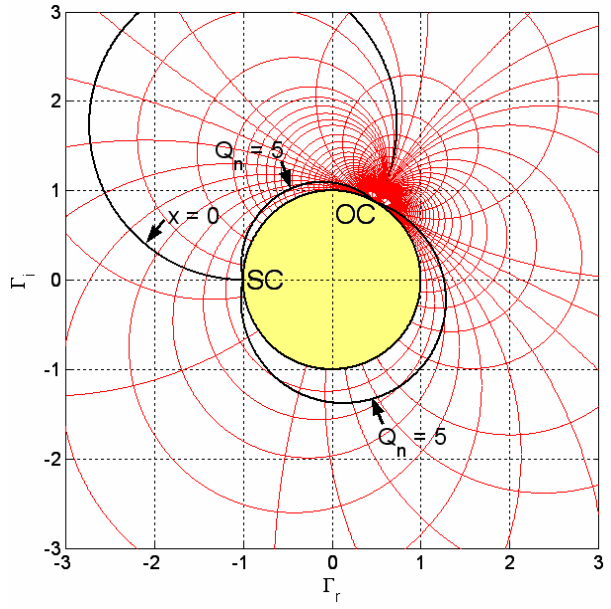

Figure 5. Plot of $Q_n = 5$ circles on the extended T-chart when $\phi = -150^\circ$.

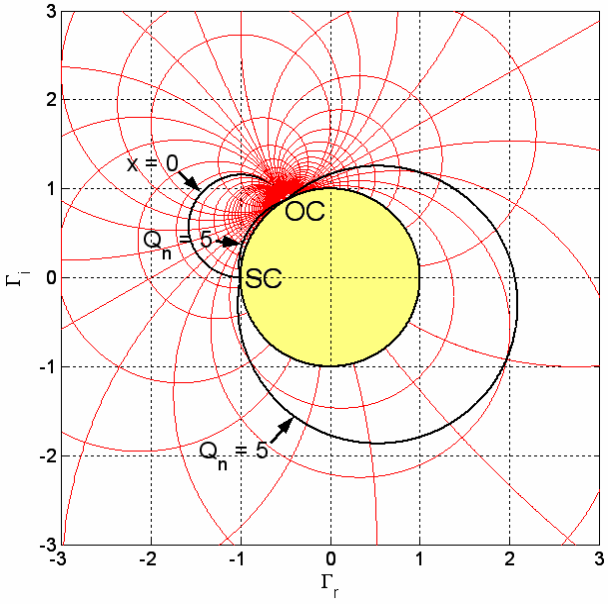

Figure 7. Plot of $Q_n = 5$ circles on the extended T-chart when $\phi = -120^\circ$.

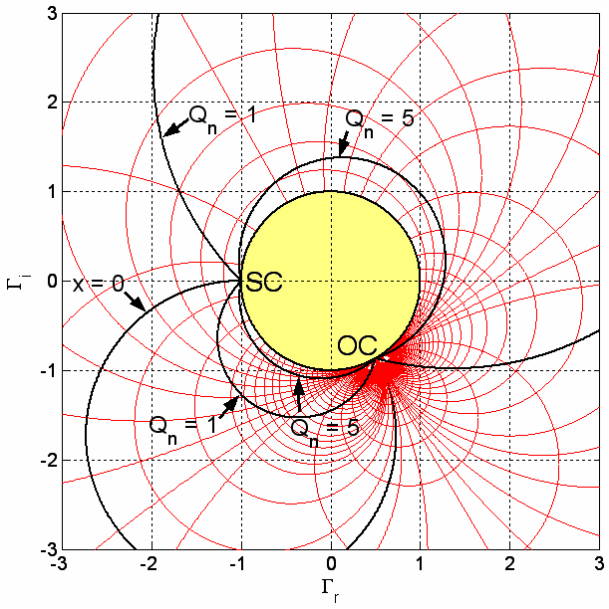

Figure 8. Plot of constant-Q_n circles on the extended T-chart for $Q_n = 1$ and $Q_n = 5$ when $\phi = 150^\circ$.

Constant-Q_n contours can be obtained by simply superimposing each constant-Q_n circle in the Γ plane as shown in Fig. 8 when $\phi = 150^\circ$. From the figure, it is observed that as Q_n increases, the closer the circles are from the unit circle for both $x > 0$ and $x < 0$, except at the short-circuited and open-circuited points on the extended T-chart. Therefore it is possible to obtain a very large constant-Q_n circle when Q_n is very small.

V. Conclusions

In this study, we extend the generalized constant-Q_n circles on the standard T-chart to be plotted on the extended T-chart. It is found that associated circle equations for both cases are the same. The only difference is the valid range of ϕ for plotting. In this case, we concentrate on the region that is outside the unit circle in the Γ plane. It is found that all constant-Q_n circles are intersected at the short-circuited and open-circuited points on the extended T-chart. In addition, the circles for $x > 0$ and $x < 0$ are generally not a symmetrical image of each other, except when $\phi = 180^\circ$. The generalized constant-Q_n circles on the extended T-chart can be employed as a tool in the design of lossless matching network when dealing with CCITLs with active characteristic impedances with a specified Q_n.

Abstract — **In this paper, a tight coupler designed for a single layer substrate is proposed. The technique extends the previous proposed concept which combines the microstrip line and coplanar waveguide structure to apply with multi-coupled lines, leading to a more tight-coupling design for standard PCB manufacturing process. Validation on the proposed technique is demonstrated with experiment on a 3-dB coupler fabricating with the in-house process in laboratory. From the measured results, tight coupling, being extremely difficult to achieve on a single-layer standard process, is achieved simply.**

Index Terms — **Microstrip (MS), coplanar waveguide (CPW), Lange coupler, , tight coupler, quadrature.**

1. INTRODUCTION

It is well known that a coupler is commonly used in various microwave circuits and systems. Though there are yet numerous structures proposed for coupler realization, only coupled-lines structure is always preferable for industrial application [1],[2]. This is because not only its wide band operation and simple profile, but also ease of integratibility. Design coupled lines [3] with various transmission line technologies, for example microstrip, coplanar waveguide, stripline, etc., can be done. However microstrip and coplanar waveguide technologies are mostly chosen as the process is more likely compatible with the mostly used fabrication processes nowadays, i.e. CMOS, MWMIC, and MMIC [2].

In view of coupling coefficient, coupler can be classified into two categories which are loose and tight coupling [4]. It has been well known that a tight coupling design is frequently used in microwave design. The most applied tight coupler is a quadrature 3-dB coupler [5],[6] as it is a basic building block to implement a balanced mixer [7], balanced amplifier [8], etc. More tight coupling design is also desirable for a coupled-line phase shifter [9]. Nevertheless a tight coupling design issue is always problematic.

Originally, parallel-coupled lines, the simplest coupled-lines structure, were proposed but since their failure to achieve tight coupling, then tandem coupled [10], multi-coupled [11]-[16] and multi-layer coupled lines [17]-[21] were invented. A tandem coupled line structure, composed of two loose coupled lines, can achieve very tight coupling design but only for narrow band operation. Additionally, the tandem structure needs air–bridges and consumes around twice of the circuit size required for parallel-coupled lines. Multi-coupled lines structure such as Lange coupler [15] or three-coupled lines [16] is very promising as the design provides a large bandwidth and small size. Besides, at least two substrate layers are demanded as it does need air bridges. Multi-layer couplers can provide a compact design. Still the approach does not suit for a single substrate layer.

Clearly neither of the abovementioned approaches is appropriate for the simplest standard fabrication process, hence a standard PCB process. Previous tight coupler implementation can not therefore avoid extra fabrication cost. Recently, there is an approach proposed [22] using a structure employing the microstrip (MS) and coplanar waveguide (CPW) transmission lines which is a pure single-layer circuit. The structure is succeeded with three-finger CPW coupled line structure. The bottom metal beneath the CPW coupled lines is etched and air-bridges needed are replaced with via holes. However the technique was demonstrated with a 3-dB quadrature coupler on thin substrate layer as the coupling performance partly relies on ground capacitances. Henceforth this paper presents an extended work of such mix-mode coupled lines to achieve tight coupling design with arbitrary substrate thickness. Section 2 illustrates the topology proposed. Section 3 reports the design details and results from simulation and experiment. Section 4 summarizes the work in this paper and future work.

2. PROPOSED TOPOLOGY

In fact, it is well known that multi-coupled line structure can provide a tight coupling design. Therefore here we apply the five-finger CPW coupled lines to attain a tight coupling. The structure of the proposed circuit is shown in Fig. 1. From the top view shown in Fig. 1 a), the layout of the circuit in the top view is similar to a standard Lange coupler except the introducing of conductor lines of width W_1 and length L_1. Via holes are applied to short these lines with the lower conductor plane shown in Fig. 1 b). Clearly that these lines of width W_1 operate as ground for the upper plane. The five-finger coupled lines have width of W and length of L. These coupled lines places at distance of D from the upper ground planes. The feed lines of W_2 are designed for attaining 50-Ω characteristic impedance.

Table 1
Summarized proposed coupler dimension

W	= 0.8 mm	L_1	= 16.2 mm
W_1	= 1.9 mm	L_2	= 29 mm
W_2	= 3 mm	S	= 0.2 mm
W_3	= 17.8 mm	D	= 5.5 mm
L	= 17 mm	h	= 1.6 mm

The bottom view of the circuit layout is shown in Fig 1 b). The conductor plane lies beneath the five-coupled lines are etched away. This makes the connecting between five-coupled lines simple with via holes. The dimensions of the open ground at the bottom plane are W_3, L_3, and L. The cross section view of the proposed circuit is shown in Fig. 1c).

3. Design And Experimental Results

In this paper, a 3-dB quadrature coupler on a low-cost FR4 substrate (thickness of 1.6 mm, dielectric constant of 4.4, loss tangent of 0.02) was designed to validate the proposed topology. A design procedure of this work begins with the same approach proposed in [22]. As the analysis approach is based on a quasi-static TEM model [4], the given formulae presented are not sufficiently accurate. Therefore the design procedure done in this paper indeed heavily relies on the electromagnetic (EM) calculation. Here the Momentum™ (EM software simulation) in Advanced Design System 2005 (ADS) software suite was used through out the whole design stage. EM optimization process was performed at the final stage with the constraints of 0.2 mm conductor width and space dimensions according to the limitation in our in-house fabrication process.

The dimensions of the design parameters obtained are summarized in Table I. The photographs of top and bottom views of the 3-dB coupler with SMA connector are shown in Fig. 2 a) and b), respectively. All via holes in the circuit were implemented with 0.8-mm diameter conductor wire. The size of the fabricated circuit excluding the SMA connectors is 2.3 $\times$1.78 cm^2. Circuit measurement was performed with HP8720C 2-port vector network analyzer. The SOLT calibration technique was done from 1 to 4 GHz. Two 3.5-mm standard loads were used to terminate at other two ports while measuring was performed. Six measurement data sets were collected via GPIB port and subsequently formed to four-port data by the developed program written in MATLAB™. Finally the 4-port data in S4P format was then plot in graphs with the ADS software.

Simulated (dotted line) and measured (line) performances of the experimental circuit are shown in Fig. 3 to Fig. 5. Fig. 3 shows the directed (S31) and coupling (S21) performances. Excellent agreement between simulated and measured S31 and

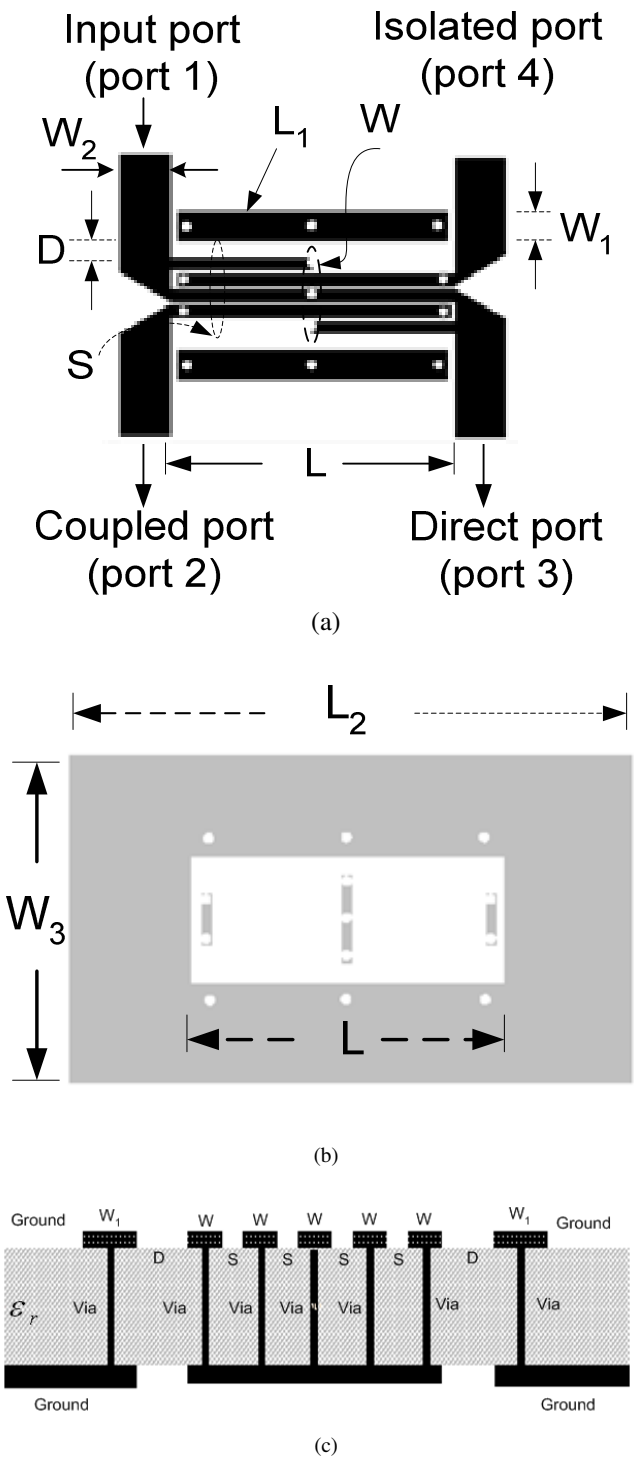

Fig. 1. Layout of the proposed circuit, (a) Top view. (b) Bottom view. (c) Cross-section view

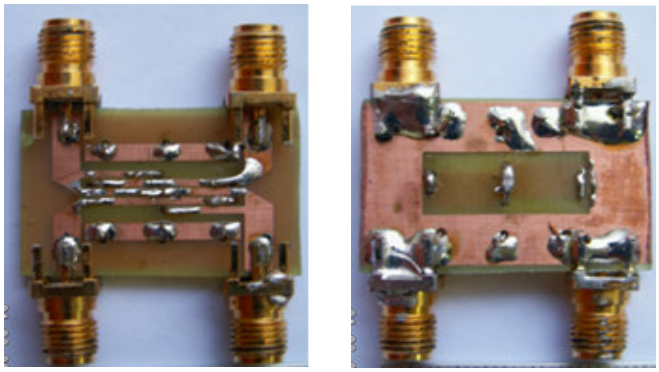
S21 are obtained. The coupler achieves -3.60 dB and -3.61 dB for measured S21 and S31, respectively, which are 0.5 dB less than the theoretical performance of a 3-dB coupler. The authors believe that this 0.5 dB loss is mainly resulted from the loss tangent behavior in FR4.

Fig. 4 shows the performances of isolation (S41) and return losses (S11). Good return and isolation performances are obtained from 1 to 3.4 GHz. At 2.45 GHz, the design achieves



(a) (b)

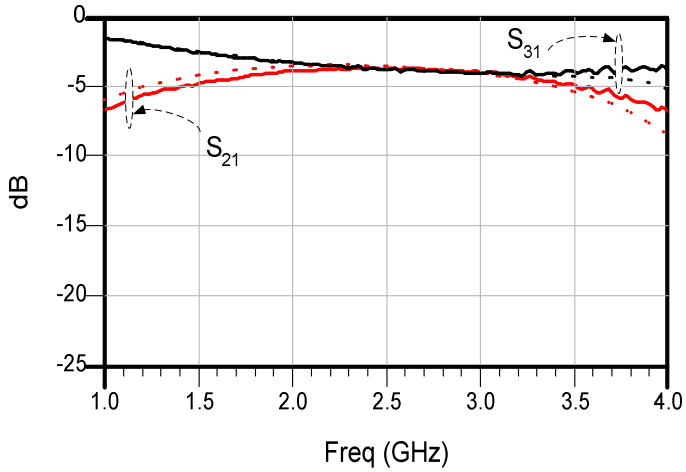

Fig. 3. Simulation and measured results of the coupled and direct ports : EM simulated (- - -), measured results (——) of the experimental circuit.

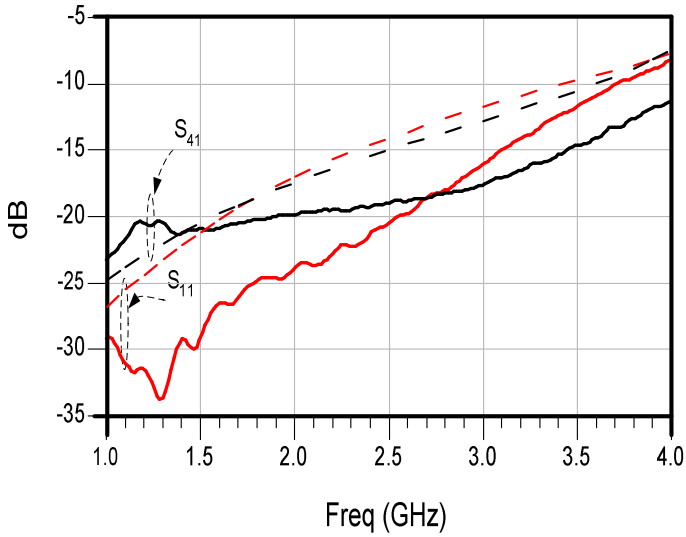

Fig. 4. Simulation and measured results of the return and isolation losses: EM simulated (- - -), measured results (——) of the experimental circuit.

S41 and S11 of -19 and -22 dB respectively. At high frequency, S41 and S11 are clearly degraded as the loss mechanism and dielectric constant are frequency dependent.

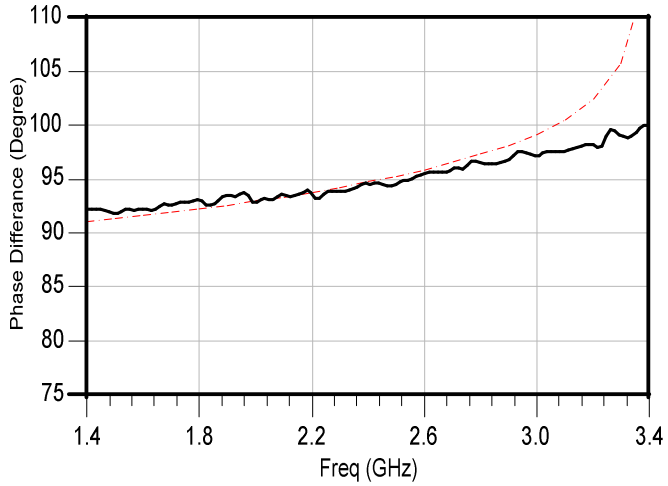

Fig. 5. Measured and simulated results of relative phase difference: EM simulated (- - -), measured results (——) of the experimental circuit.

The phase difference between the direct and coupled ports from 1.4 to 3.4 GHz is shown in Fig. 5. Nearly 90 degree, the theoretical phase difference, is obtained. A difference between measured and simulated results at high frequency region is expected to come from the dispersive nature of the FR4 which was not taken into account in our simulation.

4. CONCLUSION

A tight coupler based on five-finger coupled lines has been proposed and its experimental results demonstrate excellence performance. The circuit can achieve tight coupling on a purely single substrate layer, making it more suitable for low cost fabrication process such as a standard PCB prototyping. As shown from the experimental circuit prototyping with the in-house fabrication process, good yield performance is also gained from the proposed topology. Closed form design equations are under investigated and will be presented for facilitate the design task.

Abstract *- This paper presents the performance of the power line communication (PLC) using direct-sequence code division multiple access (DS-CDMA) technique with turbo code. In the decoding algorithm of the turbo code is using the attractive log-maximum a posteriori algorithm (Log-MAP) decoder. It is demonstrated that the performance of the system can be improved. The simulation results are verified the bit error rate (BER) performance of the power line communication systems.*

I. INTRODUCTION

Due to its omnipresence, the electric power distribution grid offers a tremendous potential for extended fast and reliable communication services. Currently, the exploitation has just started and still is far from complete. Various fields of applications can be envisioned, starting, for example, with simple inexpensive services embodied into household appliances, where data rates of some kilobits per second are sufficient. A next level might be Internet access over the wall socket, where speed is in the lower megabit range up to high-speed networking that includes fast Internet access, voice over IP, and home entertainment.

There are limits in transfer power line systems[1-4] which are in part due to some difficulties found when sending the data system. Some examples of these difficulties include impedance value (change all the time), interference signal in the power line system, attenuation which has a high value. Power line channel system[4] will insert interference signal from the source, including high voltage systems which occur from circuit breaker's working, transient occurs from thunderbolts and tools. Medium voltage systems occur from ON-OFF capacitors and switching, low voltage system occurs from working of electrical equipment when it connects to the system. These effects are used to transfer the data signal.

Direct sequence code division multiple access (DS-CDMA)[5-6] is a candidate access technique for a third generation mobile system[6]. In DS-CDMA system, signal transmission over time-varying multipath mobile radio channel produces intersymbol interference (ISI), multiple access interference (MAI), and other time-varying effect from the channel.

A turbo code, which were discovered by C. Berrou *et al.* in 1993 provide significant improvement in the quality of data transmission over a noisy channel [7]. The iterative log-maximum a posteriori algorithm (Log-MAP) is an important kind of turbo decoding algorithms [8-9].

In this paper, the performance of the power line communication using direct-sequence code division multiple access (DS-CDMA) technique with turbo coded is presented in order to increase potential and decrease bit error rate, which occurs from interference of the signal in power line systems.

II. A MULTIPATH MODEL FOR POWER LINE CHANNELS

A simple approach to rough estimation of the transfer function of power line channels was presented by Hensen [1]. A straight line can interpolate the attenuation increasing with higher frequencies, so a simple equation can be found to calculate the amplitude of the channel transfer function. As this approach does not consider multipath propagation and the resulting notches of the channel transfer function, more detailed models had to be developed. Multipath propagation approaches, which are suitable for describing the transmission behavior of power line channels, have been proposed by Philip's [2] and Zimmermann [3]. Philip's' echo model describes the channel impulse response as a superposition of N direct pulses representing the superposition of signals from N different paths. Each of these impulses is multiplied by a complex factor ρ_i and delayed by time τ_i. The factors ρ_i represent the product of reflection and transmission factors along each echo path. This leads to the complex channel transfer function

$$H(f) = \sum_{i=1}^{N} \rho_i e^{-j2\pi f \tau_i} \quad (1)$$

This model allows realistic reproduction of notches of the channel transfer function and is therefore well suited to describe indoor channels where the low-pass characteristic of the channel is not relevant. For the description of channels that show such low-pass behavior like typical European access networks, Zimmermann has proposed an adapted echo model that contains an additional attenuation factor [3]. This model represents the superposition of signals from N different paths,

each of which is individually characterized by a weighting factor g_i and length d_i. Furthermore, frequency-dependent attenuation is modeled by the parameters a_0, a_1, and k. Eventually, the following equation can be formed

$$H(f) = \sum_{i=1}^{N} g_i e^{-(a_0 + a_1 f^k) d_i} e^{-j2\pi f \frac{d_i}{v_p}} \quad (2)$$

The Eq.(2) describes a universal and practically useful form of the complex transfer function for power line channels. While the first exponential function describes attenuation, the second one, including the propagation speed v_p, represents the echo scenario. The parameters for the multipath model can be obtained from measurements of the complex channel transfer function. The attenuation parameters a_0 (offset of attenuation), a_1 (increase of attenuation), and k (exponent of attenuation) can be obtained from the magnitude of the frequency response. To determine the path parameters d_i and g_i, the impulse response is necessary. The impulse response gives information about the time delay of each path, which is proportional to d_i. The weighting factors g_i can be obtained from the amplitude of each impulse.

III. DIRECT SEQUENCE CODE DIVISION MULTIPLE ACCESS

DS-CDMA is the method that allows the data signal to directly modulate with digital signal. The data signal can be achieved in both an analog and a digital signals. The data signal will multiply the code signal directly and then bring the signal to modulate with the carrier signal. This paper will consider the data transfer through power line channels by the DS-CDMA system, which has the following model.

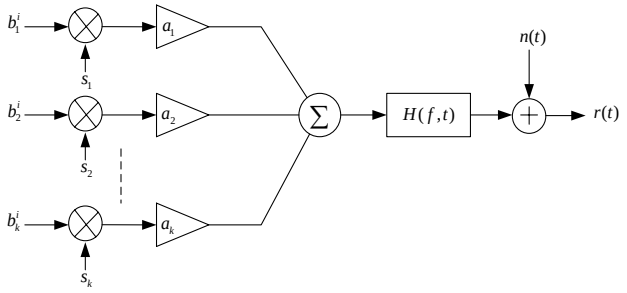

Fig. 1 Transmitter Model

In consideration of the data transfer model in the DS-CDMA system through power line channel, which has noise in additive white Gaussian noise (AWGN), and assign users in the system for k people, b_k^i is a data bit at i of user k (which has T_s time period of signal), a_k is size of acceptable signal from receiver k, s_k is spread code of user k, which has chip equal to L_c, allows the following formula to be formed :

$$s_k(i) = \sum_{i=0}^{L_c - 1} s_i(i) x(t - iT_c) \quad (3)$$

A formula showing the collective signal from the receiver can be written as follows:

$$r(t) = \sum_{i=0}^{\infty} \sum_{k=1}^{K} a_k^i b_k^1 s(t - iT_s) * h(t) + n(t) \quad (4)$$

Receivers in DS-CDMA system's duty is separate to each user, where the users' receiver including despread code of each user and integration circuit can be shown in the Fig. 2 :

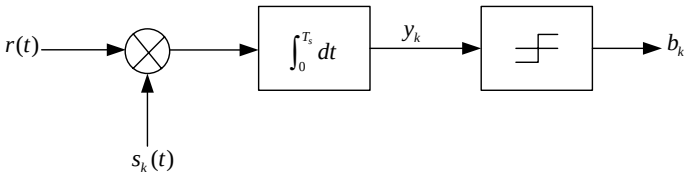

Fig. 2 Receiver Model

We observed that each user's receiver using only the own spread data in separate wanted signal then bring the signal past to bit decision circuit in order to get the designed data. If y_k is outcome signal from user k's receiver at iT_S, we can write following formula:

$$y_k = \int_0^{T_S} r(t) s_k(t) dt \quad (5)$$

The decision output of the detector can be defined as

$$b_k = \mathrm{sgn}(y_k) \quad (6)$$

IV. TURBO CODES [8]

A. Turbo Encoder

Turbo coding, illustrated in Fig. 3, uses a parallel forward error control (FEC) encoding scheme. With this scheme, the information is systematically encoded by two separate encodes. Often, the two encodes are identical, and to ensure that they do not product the same output, the information bits are reordered through the use of a pseudorandom interleaver before the second encoding stage. This pseudorandom interleaver is often referenced to as the turbo interleaver to distinguish it from channel interleavers. The information bits and the parity bits generated by the two encoders are then transmitted over the channel. In a typical turbo encoding scheme, the parity bits are punctured in a repeating pattern to increase the code rate, but this is not a requirement and puncturing refers to the omission of certain parity check bits in the code so as to increase the data rate.

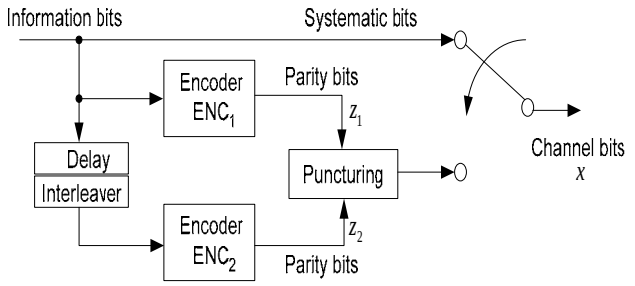

Fig. 3 Rate ½ turbo encoder.

B. Turbo Decoder

In this paper, we using the attractive Log-Map decoding algorithm, therefore we will briefly describe the Log-Map decoding turbo codes in this section. The general structure of the iterative turbo decoder is shown in Fig.4 [10]. Two component decoders (dec1 and dec2) are linked by interleavers (I). In this figure, u_k is the systematically encoded channel output bit, Y_{1k}, Y_{2k} are the parity bits transmitted from the associated component encoder respectively, Λ_{12}, Λ_{21} are the extrinsic information from the other component decoder, and $\hat{u}_k$ is the output of the hard decision (HD) of the last component decoder after the iteration is finished.

According to output *Y*, the MAP algorithm count the probability

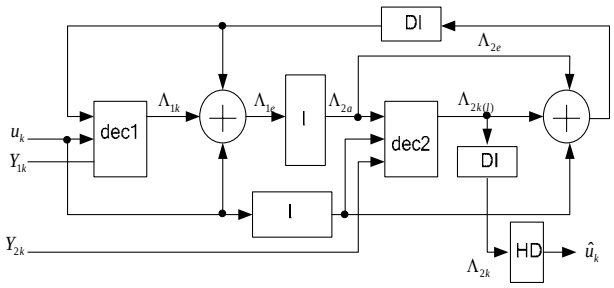

Fig 4. Turbo decoder schematic.

of every u_k = +1 and u_k = -1. That is the $L(u_k \mid Y)$,

$$L(u_k \mid Y) = In\frac{P(u_k = +1 \mid Y)}{P(u_k = -1 \mid Y)}$$

$$= In\frac{\sum(s',s) \Rightarrow u_k = +1 \alpha_{k-1}(s')\gamma_k(s',s)\beta_k(s)}{\sum(s',s) \Rightarrow u_k = +1 \alpha_{k-1}(s')\gamma_k(s',s)\beta_k(s)} \quad (7)$$

$$L(u_k \mid Y) = \left\{ \ln \sum_{(s',s)\Rightarrow u_k=+1} e^{A_{k-1}(s')+\Gamma_k(s',s)+\beta_k(s)} - \ln \sum_{(s',s)\Rightarrow u_k=-1} e^{A_{k-1}(s')+\Gamma_k(s',s)+\beta_k(s)} \right\} \quad (8)$$

Then if we use the approximation:

$$\ln \sum_i e^{x_i} \approx \max(x_i) \quad (9)$$

$$L(u_k \mid Y) = \left\{ \max_{(s',s)\Rightarrow u_k=+1} [A_{k-1}(s') + \Gamma_k(s',s) + B_k(s)] - \max_{(s',s)\Rightarrow u_k=-1} [A_{k-1}(s') + \Gamma_k(s',s) + B_k(s)] \right\} \quad (10)$$

This is the Max-Log-Map algorithm. However the performance is slightly degraded compared to the MAP algorithm due to the approximation of Eq. (9). When used for the iterative decoding of turbo codes, it is found that the degradation results a drop in performance of about 0.35 dB. However, the approximation can he made exact by using the Jacobian equation:

$$\log\{\exp(x_1) + \exp(x_2) + ... + \exp(x_n)\} = \max_{i\in(1,2,...,n)}(x_i) + \log\left\{\sum_i^n \exp(x_i - \max(x_i))\right\} \quad (11)$$

when $\Delta = \exp(x_1) + \exp(x_2) + ... + \exp(x_n) = \exp(x_\Delta)$ $f_{(x)}(x = |x_\Delta - x_n|)$ can be thought of as a correction term.

Therefore the Log-Map algorithm is given by

$$\log\{\exp(x_1) + \exp(x_2) + ... + \exp(x_n)\} \approx \max_{i\in(1,2,...,n)}(x_i) + f_{(x)}(x = |x_\Delta - x_n|) \quad (12)$$

V. NUMERICAL RESULTS

The BER performance of the proposed DS-CDMA with turbo coded for the PLC channel receiver is presented in this section. Besides the measurement data in Fig. 5, simulation results are derived from the following parameters [9], length of transmission information is equals to 1 kbits, the length of the individual path of the PLC channel is 200 m, frequency response of PLC channel is 20 MHz, an attenuation parameter $a_0 = 9.4\times10^{-3}$ and $a_1 = 7.8\times10^{-10}$, exponent of the attenuation factor $k = 0.7$ and weighting factor for path $g_i = 0.64$. And the parameters for the turbo code system : code generator metric = [1 1 1;1 0 1] with constraint length = 3, channel code rate $R = \frac{1}{2}$ and using Log-Map decoding algorithm, number of iteration for turbo decoder = 1, and DS-CDMA have chip rate = 128 bits.

Fig. 5 shows the BER performance comparison of the system with transfer data range = 1000 bits. From Fig. 5, it is evident that the performance of the system using DS-CDMA with turbo code technique provides a less BER than using only DS - CDMA.

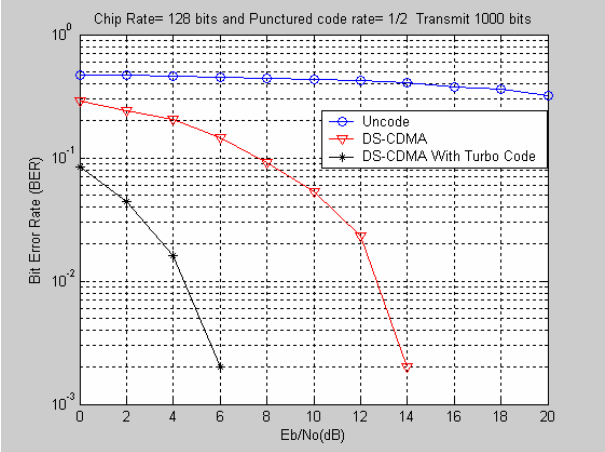

Fig. 5 BER comparison (Data = 1000 bits)

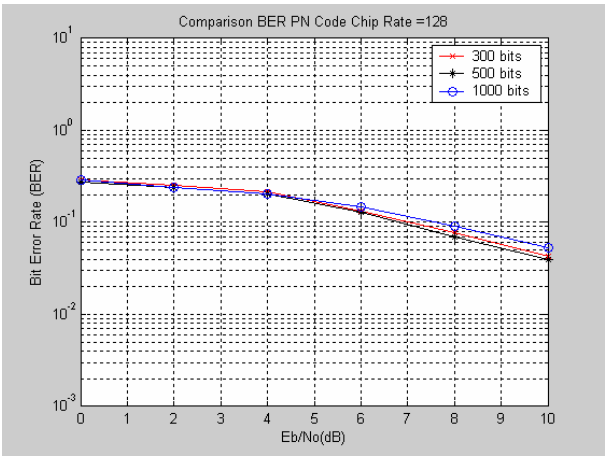
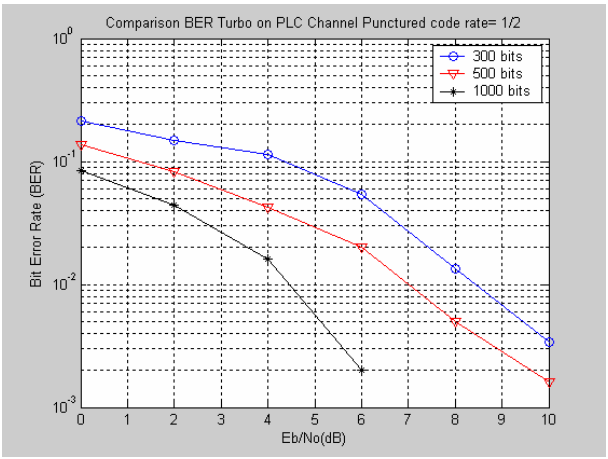


(a) DS-CDMA



(b) DS-CDMA with turbo code

Fig. 6 BER comparison

Fig. 6 shows the BER performance comparison of the system in verities transfer data rate. Fig. 6(a) shows the BER performance of the system by using DS-CDMA technique with data range = 300, 500, and 1000 bits, respectively. Fig. 6(b) shows the BER performance of the system by using DS-CDMA with turbo codes technique with data range = 300, 500, and 1000 bits, respectively. From the Fig 6(a), it is seen that the performance of the system is slightly same. And from the Fig. 6 (b), it is demonstrated that the performance of the system by using DS-CDMA with turbo code can be increased, if the transfer data is increased.

VI. CONCLUSION

This paper presents the performance of the power line communication using DS-CDMA with turbo code through the Additive White Gaussian Noise (AWGN) channel. From the simulation results, it can be concluded that the efficiency of the power line communication systems can greatly improved by using DS-CDMA with turbo code method.

***Abstract*- In this paper, we present the throughput, probability of bits error and average retransmission on various signals to noise ratio when comparing of M-ary parameter and bits rate of Power Line Communication (PLC) system base on the physical layer. Our study indicates that the system using TCP/IP and M-ary FSK modulation scheme for solving packet loss and packet corrupt correction that is affected by impulsive noise channels can provided the high efficiency and throughput enhancement.**

I. INTRODUCTION

Nowadays, one of wireline communication technology that are attractive for the provision of narrow-band communications that is Power line Communication (PLC). It uses existing electric lines to transmit data communication for home users or small business. Power lines in-house are low voltage lines on the basic of European standard, in particular the European CENELEC standard EN 50065 [1]. The advantage of using PLC is that it can reduce or eliminate the cost of wiring new networks. However, the noises in PLC are present in many types. The typical noises over power line are background noise, thermal noise, narrowband noise, impulsive noise etc. This paper, our main interest is impulsive noise and ignores other noises. An impulsive noise have caused by variety of sources, such as switching noise, adverse channel environments in a communication system, clicks from computer keyboards, and so on.

The main contribute of this paper is proposed to use TCP/IP and M-ary FSK modulation for studying the performance of PLC that is affected by impulsive noise. Simulation results are given to support the scheme in terms of the probability of bits error, average packets retransmission and throughout compared with signal to noise ration (SNR) when M=2 and 4. In order to, our can be analyze the optimum performance of system and reliability.

The remainder of this paper is organized as follows. Section II reviews the architecture and standard of the PLC, Impulsive noise model, M-ary FSK modulation scheme and protocol stack respectively, section III describes the simulation, section IV presents the simulation results, and section V describe the conclusions

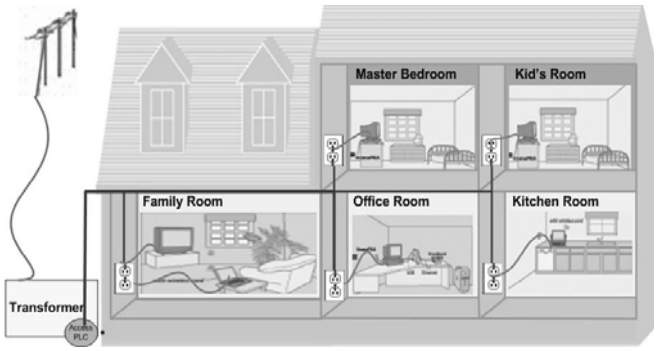

Figure 1: Typical Architecture of PLC

II. POWER LINES

A. Power Line Architectures and Standard

In power line system where the transmission medium is the electrical power network based on the European CENELEC standard EN 50065 include parameters as show in Table I. This standard rules the use of frequency range from 3 to 148.5 kHz on Low voltage while the range from 95 to 148.5 kHz is for the use, mainly, within buildings and operating home users. The architecture of PLC system is shown in Fig. 1. With the systems provided, the user can be send-receive data via power lines that are already installed. The data will be transferred data with TCP stack protocol. With the chosen modulation scheme of M-ary FSK, this M-ary parameter is the number of frequencies used in the modulated signal. Using M-ary FSK, a binary 1 for a high frequency and binary 0 for low frequency [2-4].

TABLE I
PARAMETER AND STANDARD PLC

Parameter	PLC
Standard	EN 50065 (specific standard)
AC frequency	50 or 60 Hz.
Low Voltage level	220 - 400 V.
Frequency range for in-house	95 - 148.5 KHz.
Transmission Rate	1 - 10 Mbps
Usable distance	about 500 meter
Work law	use send - receive data by electric lines in house

B. Impulsive Noise Model

Impulsive noise is non-stationary, binary state sequence of impulse with random amplitudes and random instances of occurrence. An impulsive noise sequence can be modeled as an amplitude-modulation binary state sequence, and express as [5-6]

$$n_I(m) = n(m)b(m) \tag{1}$$

Where *b(m)* is binary-value random sequence of ones and zeros, that signals the presence or absence of noise pulse, and *n(m)* is random noise process. the autocorrelation and power spectrum are express as binary state function depend on the "on/off" state of impulsive noise at time m. A real impulsive-type noise sequence, $n_I(m)$, as the output of channel filter excited by an amplitude modulation random binary sequence as

$$n_I(m) = \sum_{k=0}^{P-1} h_k n(m-k) b(m-k) \tag{2}$$

Where h_k is impulse response of a filter that models the duration and the shape of each impulse.

An alternative for an impulsive noise sequence is binary model, in which the state S_0 corresponds to the "off" condition when impulsive noise is absent; in this state, the model emits zero-valued samples. The state S_1 corresponds to the "on" condition; in this state the model emits short-duration pulses of random amplitudes and durations. The probability of a transition from state S_i to state S_j is denoted by a_{ij}. In its simplest form, as shown in Fig.2, the model is memoryless, and the probability of a transition to state S_i is independent of the current state of the model. In this case, the probability that at time t+1

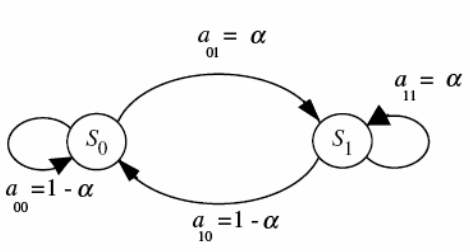

Figure 2. A binary-state model of an impulsive noise generator.

the signal is in the state S_0 is independent of the state at time t, and is given by

$$P(s(t+1)=S_0 \mid s(t)=S_0) = P(s(t+1)=S_0 \mid s(t)=S_1) = 1-\alpha \tag{3}$$

where s_t denotes the state at time t. Likewise, the probability that at time t+1 the model is in state S_1 is given by

$$P(s(t+1)=S_1 \mid s(t)=S_0) = P(s(t+1)=S_1 \mid s(t)=S_1) = \alpha \tag{4}$$

In general, the power line is share by all of users connected that impulsive noise may be present different on time of day depend electronic device are plug-in.

C. M-ary FSK

The M-ary communication scenarios that the M-ary is form multi-level of symbol. These symbols are indexed m by the integers 0 through M-1. In here, we consider the M-ary Frequency Shift Keying (M-ary FSK) where the source wishes to send one of M symbols. The M signal waveforms, u_0, u_1,… u_{M-1} or u_m, that are available to the transmitter. The u_m controls a switch that selects the modulated frequency from a bank of M oscillators. The modulation is continuous phase at the edges of symbols. Mathematically can write as

$$u_m(t) = \sqrt{\frac{2E_s}{T_b}} \cos\left(2\pi f_c t + 2\pi m \Delta f t\right) \tag{5}$$

where $E_s=kE_b$ is the energy per symbol, $T=kT_b$ is the symbol interval, f_c is carrier frequency, and Δf is the frequency separation between successive frequencies that is, $\Delta f = f_m - f_{m-1}$ for all $m = 0,1,2,\ldots,M-1,\ 0 \le t \le T$, when M is an integer power of 2and $f_m = f_c + m\Delta f$.

D. Protocol Stack

TCP/IP is a communication protocol stack designed to provide a reliable data stream between two hosts. It is a popular means of communicating data over a network. A reliable transport typically uses a connection-oriented to establish connection [7]. The data can be transmitted from transmitter to receiver on time digital duplex (TDD) channel. In a TDD that shares carriers between the uplink and downlink, the resource being switched in time so users are allocated one or more time slots for uplink and downlink transmission. The main advantage to TDD operation is that it allows asymmetric flow which is more suited data transmission. Therefore, the PLC system presented in this paper operated base on TDD scheduling algorithm, which is basically operated with the by-exchanges of round-robin policy, many be wasted by exchanges of POLL or NULL packets even when there no data waiting for transmission in queues. The transmitter will transmit and receive from receivers that are allocated address and are active at that time. If there is nothing to send, the transmitter may either omit that receivers or transmit a NULL packet.

III. SIMULATION

The TCP/IP over PLC system of this simulation as show in Fig. 3 that consist of three parts: 1) Transmitter 2) Noise and Receiver, respectively.

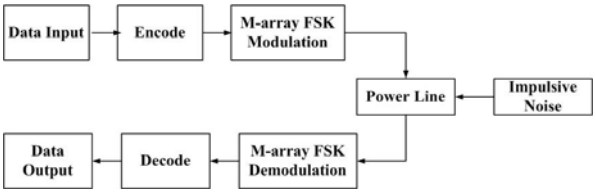

Figure 3. Block diagram of system.

Method of the transmitter is describes as follows. The input data are encoded by binary code and then modulated using M-ary FSK modulation, M-ary parameter vaule are set to 2 and. 4 over TDD channel with TCP/IP protocol. Outputs from the transmitter are sent to the receiver via power line. The received signal includes the effect of impulsive noise channels, with zero mean and 1-sided power spectral density. In the receiver, the received signals are demodulated and sent to decoder module. This received data stems are compared against with the input data stems from the transmitter. The differences from the comparison are used for calculating the BER. The program simulated of this paper, as show in Fig.4

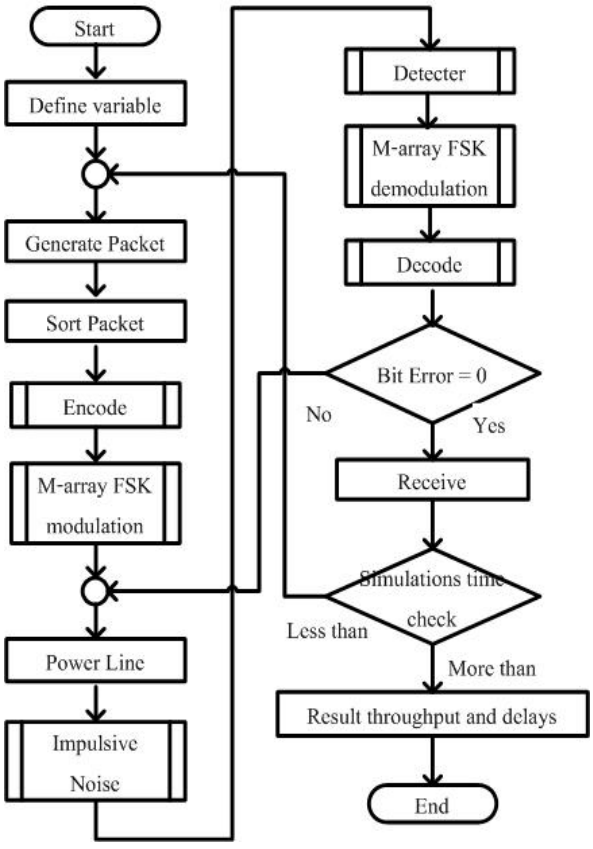

Figure 4. Flow chart of TCP/IP over PLC system contaminated with Impulsive noise

This paper uses TCP/IP protocol for flow control. Packet loss and packet corruption are main problems in PLC system. We solve these problems using TCP/IP. An acknowledgment (ACK) is generated only after the receiver receives the data correctly. TCP transmitter is guaranteed that the data have reached the receiver correctly when it receives an ACK. Also, Negative Acknowledgement (NAK) is generated when the packet loss or packet corruption. In the case that binary code cannot correct the packet corruption, the NAK packet is send out to the transmitter for requesting packet retransmission. Then, the transmitter will keep retransmitting the packet until it corrects.

IV. SIMULATION RESULTS

In this section, we present simulation results that show performance improvement of PLC system when using TCP/IP and M-ary FSK modulation scheme. In the simulation, we compared M-ary parameters of FSK modulation that are two and four. The bit rates used for M=2 are 10 kbps, 20 kbps, 30 kbps and 20 kbps, 40 kbps, 60 kbps for M=4. For the noise on power line, we considerate impulsive noise and ignore other noise. Therefore, we indicate the occurrence of impulsive noise with various SNR from 0 to 12 and amplitude of impulsive noise.

Fig. 5 shows the probability of bits error. The data contaminated with impulsive noise of PLC for the case of M=2 and M=4 when various bit rate. The result shows that the probability of bits error decreased when SNR increases (decreased noise). And in the case of M=4 the probability of bits error is lower than in the case of M=2 at same the symbol rate, that the symbol rate of M=4, if we rewrite in bit rate form it has double value of M=2. In the same trend, Fig. 6 shows the average packets retransmission decreases as SNR increases. However, the both figures have show in the relation between the data transmission and the average packets retransmission when the data has a few bit errors rate, the number of average packets retransmission is also low.

Fig. 7 shows the throughput is succeeding packets complete in transmission. They illustrate the throughput of data using TCP/IP over PLC system that has effect of impulsive noise. The curves present the different throughput that has performed by TCP/IP and M-ary. The results of increasing M-ary value, which can be increase throughput due to one symbol, have number of bits increasable. At M=4 that has throughput higher than M=2 and the throughput will be limit to maximum bit rate of each M-ary value, which depends the effect from impulsive noise as show in SNR. According to the throughput curve where SNR is equal to five (Selected SNR value can be seen all vary M-ary) the throughput of M=4, bit rate=20 kbps approaches the maximum bit rate more rapidly than M=2, bit rate 10 kbps that represent the same symbol rate and the both M=2 and M=4 at the symbol rate increases to 20 symbols/s, 30 symbols/s and show the same result as previous above.

Therefore, the relation of all simulate figures when considered the throughput of M=4 and bit rate =20 kbps these are given the optimum performance of system because this M-

ary value can be transfer many data and low probability of bits rate. Both values are conceded for simulation result that shows perform of TCP/IP protocol and M-ary FSK method. In this perform increasing the noise immunity of data transmissions and perform can be improve performance of PLC system.

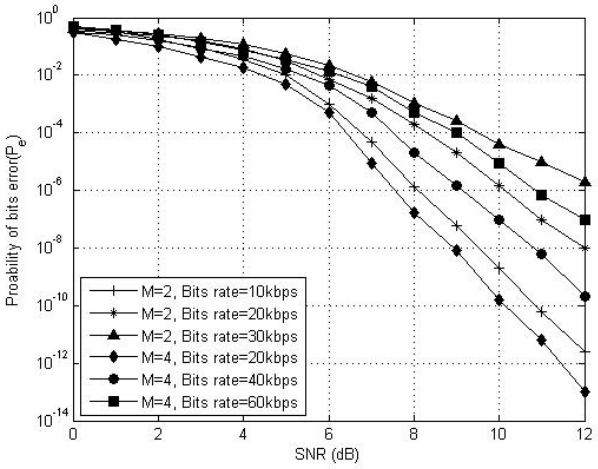

Figure 5. Probability of bits error versus SNR when M=2 and 4

V. CONCLUSION

In this paper, we presented a simulation of procedure to evaluate the throughput of PLC system with corrupted by impulsive noise that we considered data transmission on TDD channel used TCP/IP protocol and M-ary FSK method. An advantage of TCP/IP designed to provide a reliable data stream between two hosts and M-ary FSK increased the noise immunity of modulation format that data receive have correction and reliability. Therefore, the simulation results also indicate that the TCP/IP and M-ary FSK method can provide a useful tool for performance improvement.

***Abstract*- Recently, communication in power line system is very interesting in data communication because of convenient and inexpensive solution. In this paper, we propose the modulation data with binary Chaos Shift Keying (CSK) scheme. Additionally, we combined the data with Direct Sequence Spread Spectrum (DSSS) technique for data communication in power line system, and impulsive noise is considered.**

I. INTRODUCTION

Chaotic signals are nonperiodic waveforms, generated by deterministic systems, which are characterized by a continuous "noise-like" broad power spectrum. In the time domain, chaotic signals appear random signals what are indistinguishable [1]. Chaotic systems are characterized by "sensitive dependence on initial conditions" [2]; an arbitrarily small perturbation eventually causes a large change in the state of the system. Equivalently, chaotic signals decorrelate rapidly with themselves. The autocorrelation function of a chaotic signal has a large peak at zero and decays rapidly. Thus, chaotic signals share many of the properties of stochastic processes; they also possess a deterministic structure that makes it possible to generate noise-like chaotic signals in a theoretically reproducible manner. In particular, a continuous-time chaotic system can be used to generate a wideband noise-like signal with robust and reproducible statistical properties.

Due to its wide-band nature, a signal comprising chaotic basis functions is potentially more resistant to multipath propagation than one constructed of sinusoids. Thus, chaotic digital modulation, where the digital information signal to be transmitted and mapped to chaotic waveforms, is potentially useful in propagation environments where multipath effects dominate. [3]

In this paper, we investigate the chaotic signals over direct sequence spread spectrum (DSSS) for power line data communication with impulsive noise. The article composes of the following sections. Section II, we mainly use the theory of binary Chaos Shift Keying (CSK) and DSSS communication system to explain and study the power line and impulsive noise model in power line system. By the way, the simulation model is proposed in section III, while section IV presents the result of the simulation itself. Finally, the conclusions are given in section V.

II. THEORY

A. Chaotic signal and Binary Chaos Shift Keying(CSK)

In a binary Chaos Shift Keying (CSK), each symbol is represented a weighted sum of chaotic basis functions, $g_j(t)$. The binary CSK transmitter is shown in Fig.1. The sample function $s_i(t)$ composes with $g_1(t)$ or $g_2(t)$, depending on whether symbol "1" or "0" is transmitted. From Fig. 1, the required chaotic basis functions could be generated by different chaotic circuits or produced by a single chaotic generator, whose output is multiplied by two different constants.

In both cases, the transmitted binary information is mapped to the bit energies of chaotic sample functions. In the chaotic digital communications systems, as in the conventional communications schemes, the transmitted symbols could be recovered using either coherent or noncoherent demodulation techniques.

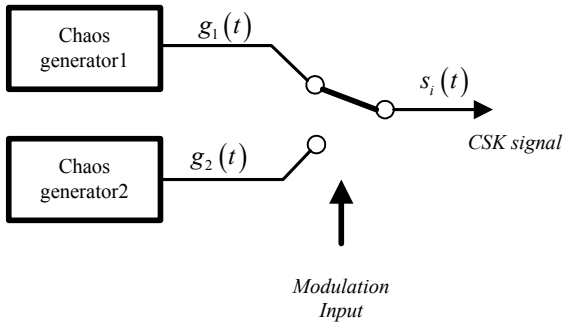

Fig. 1 Chaotic Sift keying modulation.

B. Coherent Demodulation of CSK

Coherent demodulation is accomplished by reproducing copies of the basis functions in the receiver, typically by means of a synchronization scheme [3]. When the synchronization is exploited, the synchronization scheme must be able to recover the basis function ($s_i(t)$) from the corrupted received signal.

If a single sinusoidal basis function is used, a narrow-band phase-locked loop (PLL) will be used to recover it. Noise corrupting the transmitted signal is suppressed because the low-pass property of the PLL. When an inherently wideband chaotic basis function is used, the synchronized circuit must

also be wideband in nature. Typically, both of the amplitude and phase of the chaotic basis function must be recovered from the received signal. Because of the wideband property of the chaotic basis function, narrow-band linear filtering cannot be used to suppress the additive channel noise. Fig.2 exhibits a coherent (synchronization-based) receiver using the binary CSK modulation with two basic functions, $g_1(t)$ and $g_2(t)$. The synchronization circuits, which is working at the receiver base, will try to reproduce the basic functions again but including the as-received noisy sample function, $r_i(t) = s_i(t) + n(t)$.

An acquisition time, Ts, is allowed the synchronization circuits to lock the incoming signal. The recovered basis functions $\hat{g}_1(t)$ and $\hat{g}_2(t)$ are then correlated with $r_i(t)$ for the remainder of the bit duration, T. A decision is made on the assumption of the relative closeness of $r_i(t)$ when $\hat{g}_1(t)$, and $\hat{g}_2(t)$ is multiplied by the observation variables, z_{i1} and z_{i2} respectively.

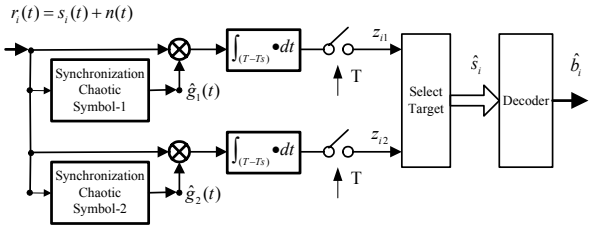

Fig. 2 Coherent Demodulation of CSK

C. *Direct Sequence Spread Spectrum system*

The main objective of spread spectrum (SS) sequence is protecting the communication signals from any interfere and illegally exploit by unintended users. In some contexts, it is important that the unintended user could not determine whether a communication signal is active or not. [2]

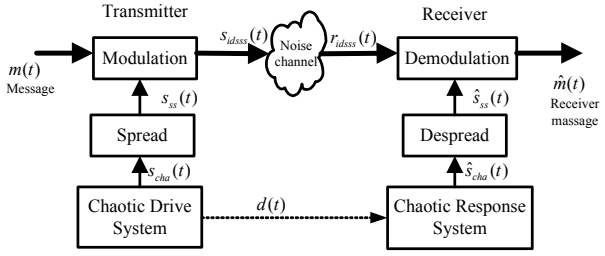

Fig. 3 Chaotic Spread Spectrum System.

This requirement of the communication signal must provide a low probability of detection (LPD) and commonly referred to LPD signals. In some case, a low probability of detection (LPD) also named a low probability of intercept (LPI) which is provide some different in the working processes. LPI signals may be detectable but extracting features from them is very difficult. Frequently, both of LPD and LPI capabilities are desired in application [2].

To achieve these objective, a SS system usually operates with communication bandwidth, B, which is much wider than the massage bandwidth. Since a bit interval of T seconds results in a message bandwidth of approximately $1/T$ Hz, the communication bandwidth consists of approximately BT non-overlapping signal intervals. The different SS module strategies could utilize this wide communication bandwidth to create uncertain released signal in a different way.

In Direct Sequence (DS), a broadband modulation waveform is used to spread the signal energy over the entire communication bandwidth at each real time of application. An unintended user, who uses an intercept bandwidth of $1/T$ Hz, will only receive a fraction of the signal power. On the other hand, if the intercept bandwidth is equal to the communication bandwidth, B, the received noise will increase with a factor BT. Vice versa, the SNR of the intercepted signal is significantly reduced.

According to the DS, the required signal spreading is achieved by modulating of the message signal with a noise-like waveform that has nearly uniform power spectrum over the communication bandwidth. The modulation waveform should display considerately complicate and unpredictable when it is viewed by an unintended user even it is being completely deterministic and easily recreated at the various communication receivers, in facts. So, the chaotic signals are the good candidates to work as the modulation waveform for SS communication systems because of their broadband and noise-like characteristics. Furthermore, the synchronized chaotic systems can be used at the communication receivers to coherently de-spread the received signal.

Many variations of SS communication systems which created on synchronized chaotic systems are possible to apply in a real application. For example, Fig. 3 illustrate one possible approach. The primary signal processing components of the transmitter consist of a chaotic drive system, followed by a whitening filter and a DS modulator. The receiver consists of a synchronizing chaotic response with the subsystem followed with identical whitening filter and a demodulator. The RF section of this system has been omitted. We assume that the transmitter and communication receiver are linked through a common drive signal, $d(t)$. The transmitter and communication receiver form a chaotic drive system and a stable response subsystem, respectively. Then, the output signal of the response subsystem, $\hat{s}_{cha}(t)$, will synchronize to the signal, $s_{cha}(t)$, present at the transmitter. The purpose of the whitening filter is to product a nearly uniform power spreading from the chaotic signal, $s_{cha}(t)$. The whitened signal, $s_{ss}(t)$, will be a nearly ideal spreading signal because of its broad and uniform Fourier spectrum. If the message signal, $m(t)$, is multiplied by $s_{ss}(t)$ at the modulator, the transmitted signal, $s_{idsss} = m(t) + s_{ss}(t)$, will also have a broad Fourier spectrum. By property scaling $s_{ss}(t)$, the average power in s_{idsss} will nearly the same as the average power in $m(t)$. Since s_{idsss} occupies a bandwidth which is larger than the bandwidth of $m(t)$ by a factor of approximately BT, they

must be decrease with the power spectral density of s_{idsss}. By making the communication bandwidth very large, the transmitted signal, in principle, can be hidden in the background noise which would make it very difficult to detect.

The communication receivers can easily recover the transmitted message since the dispreading signal, $\hat{s}_{ss}(t)$, will identify the spreading signal, $s_{ss}(t)$. Once the transmitter and receiver have synchronized, the demodulator performs the reverse of the modulation operation then $m(t)$ can be recovered. The required SNR of the recovered message is as same as the requirement from the conventional system which is having the same error rate with the same baseband modulation scheme.

D. Power Line system

Cable of power line system is not designed for transmitted data in telecommunication. It provided high impedance and more noise. The noise is impulsive noise. Fig. 3 shows the Bernoulli-Gaussian Model in impulsive noise process. The random time of the presence of the impulses is modeled by a binary Bernoulli-Gaussian, $b(m)$; and the amplitude of the impulses is modeled by Gaussian process, $n(m)$.

Probability of Bernoulli process [4], $b(m)$, is as the following equation:

$$P_B\left(b(m)\right)=\begin{cases}\alpha & for \quad b(m)=1\\ 1-\alpha & for \quad b(m)=1\end{cases} \tag{1}$$

Means of Bernoulli process is:

$$\mu_b=\mathrm{E}\left[\left(b(m)\right)\right]=\alpha \tag{2}$$

and a variance is:

$$\sigma_b^2=\mathrm{E}\left[\left(b(m)-\mu_b\right)^2\right]=\alpha\left(1-\alpha\right) \tag{3}$$

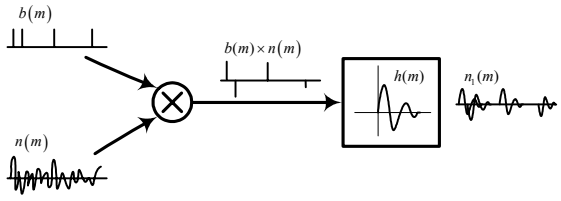

Fig. 3 The impulsive noise model.

E. Power-line Network Channel Model

Channel transfer function of a matched transmission powerline follows. In the case of unmatched junctions, part of a propagating signal reflects back to the transmitter at branch junctions due to impedance mismatch and the remainder travels through [5]. The propagation along a wire follows, so one can easily express the multipath network channel model as:

$$H(f)=\sum_{i=1}^{N} g_i e^{-\alpha(f)d_i} e^{-j\beta(f)d_i} \tag{4}$$

where N is the number of significant arrived paths at the receiver, di is the length of ith path and gi is the weighting factor of the ith path. This formulation is basically similar to what has been mentioned in [6], however, with a model for propagation constant that is appropriate for overhead MV power-lines, rather than underground cables in Europe.

III. SIMULATION MODEL

From the flow chart in Fig. 4, the main block composes of the carrier, full signal, modulation, spreading sequence, noise, de-spreading sequence, filter, and demodulation.

At first, Carrier block is chaotic signal that generated by Lorenz generator. Afterward, the full massage block will add the signal from any input massage. Then the modulation block is used in modulating the CSK with full message signals. From the modulation block, the spreading sequence block spreads module signal with the Bernoulli sequence method. The noise block is generated by Bernoulli-Gaussian Model in power line system, which generates impulsive noise and added that synchronized signal into the power line data communication. In additions, the DSSS signal is generated by dispreading sequence block and the demodulation block is also uses to retrieve the binary information that already been sent.

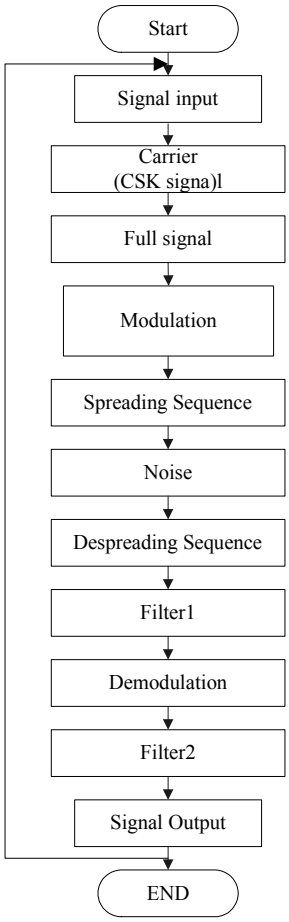

Fig. 4 Flow-chart of simulation.

IV. SIMULATION RESULTS

The simulation results is shown in Fig. 5, 6, and 7. The input signal '01100010' shows in Fig. 5(a). Fig. 5(b) presents the chaotic shift keying signal for modulation. Fig. 5(c) shows the plotted signals after passed out from the module and the spread spectrum processes. Fig. 5(d) illustrates signal receiver that pass dispreading sequence and filter1 processes. The Impulsive noise in the power line system and chaotic generator is shown in the Fig. 6 and 7, respectively.

V. CONCLUTION

A method of generating a chaotic sequence in direct sequence spread spectrum system takes advantage of their noise-like features. From the simulation results, it is clearly observed that the power line communication system has impulsive noise. However, from the simulation method, it is able to receive the correct massages just as same as the massage before encoding one.

For the future plan, we will focus on the bit error rate of CSK and DSSS method including the performance of the system when any part of modulation has changed.

***Abstract*—Position and orientation of the RFID reader and tags play an important role to the system performance in the actual installation. However, most RFID manufacturers rarely provide information on how to install the reader and tags for a specific application. In this paper, we investigate two methods to determine the best installation position of the RFID reader for road access services. An Anechoic Chamber Test and simulation provide the basic information for reader installation in the ideal environment. The field test determines the best installation position in the actual environment. The information obtained by the first method can be utilized to reduce the number of experiments in the second method.**

I. INTRODUCTION

Recently, RFID has been actively researched as a result of an announcement from Wal-Mart and US Department of Defense (DoD) who required their vendors to utilize RFID for their inventory-stock inspection by the year of 2005 [1]. RFID applications are not limited to tracking traceability logistic access control, but also widely used in transportation. In the world where security and time become a critical issue in road access control, many important places enforce vehicle to stop and verify its identity before accessing the facilities. System such as Automatic Vehicle Identification (AVI), which applied RFID technology, can be employed for security control and also help reducing the queuing time.

RFID system is a system that detects and identifies each tag based on data communication between readers and tags. The tags can be either active or passive tag. A choice between active tag and passive one is always an issue in most applications; each has significant advancetage and disadvantage. The active tag provides longer reading-range and greater penetration. The disadvantage of active tags is that the battery needs to be replaced every 2-3 years. Although the passive tags provide shorter range and poorer penetration than the active tags, the battery is not required for the passive tags. Besides the readers and tags, the system also includes a server for storing the information to validate the access code from the tags [2].

There are several RFID products available in the market. However, the information provided by most vendors of each product is insufficient for installation the reader and tags in the actual environment. In particular, the microwave wavelength products, of which performance effectiveness can be adversely affected by the environment factors such as humidity and metal. In addition, positions and orientation of the reader and tags also crucially affect the readability results.

This paper explains two methods to determine a position and orientation of the reader and tags for the best reception rate. The first method requires an access to either the anechoic chamber or electromagnetic simulation software to obtain the radiation pattern, while the second method is based on the actual installation. The first method provides the position for the ideal installation and it might not be the best position in the actual installation. The second method can determine the best position in the actual installation but it is time consuming process to obtained accurate results. The main advantage of the second method is that it does not require the knowledge of radiation patterns. However, the radiation patterns can be also utilized to reduce the number of experiments in the second method.

The paper is organized as follows: In Section II, brief specifications of the equipments under test are given. The outlines of the experiments are also discussed in Section II. The radiation patterns from the anechoic chamber and electromagnetic simulation are given in Section III. The detail on the experiments to determine the best position and orientation of the reader in the actual installation is given in Section IV. Summary is given in Section V.

II. EQUIPMENTS AND EXPERIMENTS

A. Equipments

In the experiment, a 2.4 GHz active RFID development kit (F2M07-KIT) made by Free2move Company is used as shown in Figure 1. The kit consists of RFID reader, tags, and configuration software. The developer can use the configuration software to encode tag information, set the communication protocol between reader and tags, and configure reader baud rate and output power. Detail specifications of the reader and tags are given in [3].

Figure 1 Reader and tags

The communication protocol between reader and tags is set to be Reader Talks First (RTF) so that the reader continuously transmits the signal and the radiation pattern can be measured in the anechoic chamber. In all experiments, the reader is set to transmit at the maximum power of 0 dBw or 1 watt to obtain the highest performance of both reader and tags.

The reader and tag utilize meander line antenna as shown

in Figure 2. The meander line antenna often used in the application that required a limited space, such as reader or tags. Nevertheless, its radiation pattern resembles monopole antenna. Unfortunately, the radiation patterns of the meander line antenna cannot be expressed in closed forms. In order to obtain the radiation pattern, either the full wave electromagnetic simulation or measurement in the anechoic chamber is required. It can be seen from Figure 2a that the reader is designed to utilize the diversity technique to obtain the best signal form both antennas. Since both reader and tag use the same type of antenna, we measure and simulate only the radiate pattern from the reader.

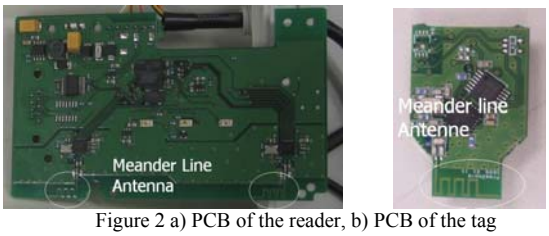

Figure 2 a) PCB of the reader, b) PCB of the tag

B. *Experiment*

An objective of the experiment is to determine the best location and orientation of the reader and tags placement on the car windshield. In this experiment, we first measured the radiation pattern of the reader to obtain the direction of the maximum transmitted power. Figure 3 illustrates the flowchart for the first experiment.

Then, the best location and orientation of the reader in the actual installation are determined by the readability of the tag. The reader is attached to either next to booth station or pole and faced the front to the road. The readability test is performed by increasing the reader tilt angle with respect to the wall toward the vehicle. If the readability is increased with respect to the previous tilt angle, then we continue to increase the tilt angle until the readability of the tags decrease. The tilt angle before decreasing in readability of the tags is the optimum reader orientation. The procedure for this experiment is summarized in Figure 4. Seven tags are attached to the windshield to determine the best tags location for all tilt angles.

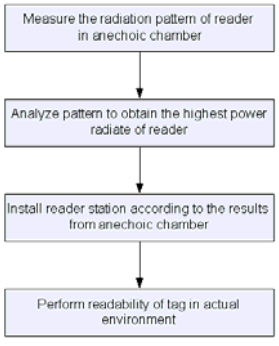

Figure 3. Flow chart for the first experiment

III. IDEAL TEST

In this section, the radiation patterns are obtained so that the best position and orientation of the reader can be determined. The radiation pattern can be obtained by either testing in the anechoic chamber or full wave electromagnetic simulation. The results from both methods are presented in this section.

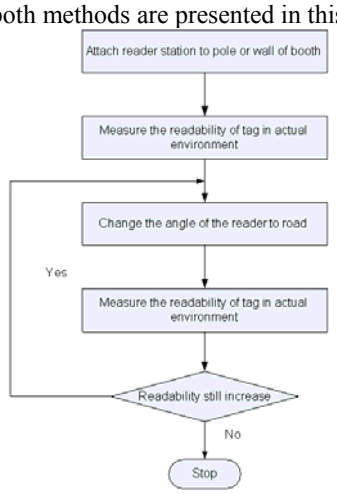

Figure 4. Flow chart for the second experiment

A. *Radiation Pattern Measurement in The Anechoic Chamber*

It would be beneficial to know the 3-D radiation pattern of the antenna. However, it is very difficult and unnecessary to measure the complete representation of antenna radiation properties [4]. Therefore, in this paper, we measured only radiation pattern of E-field of reader in E-plane and H-plane in the anechoic chamber, which considered as a controlled environment. The anechoic chamber is provided by Electrical and Electronic Product Testing Center (PTEC). Both field components (E_θ and E_ϕ) have been measured. Figure 5 shows test setup in the anechoic chamber for the radiation pattern measurement. For the H-plane, we face the reader directly to the horn antenna and then rotate it by 360° with respect to the stationary horn antenna. For the E-plane, the reader lied directly to the horn antenna and then is rotated 360° with respect to the horn antenna.

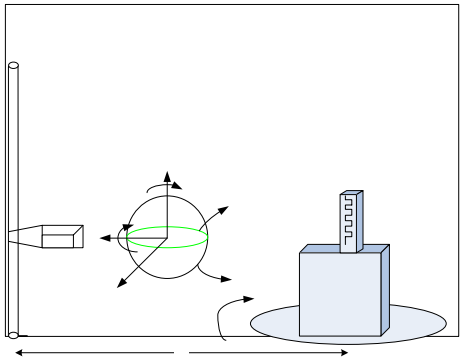

Figure 5. Testing in anechoic chamber for reader radiation pattern

The dot line in Figure 6 shows the normalized polar plot of E-field radiation pattern in H-plane. From the Figure 6, we observe that the reader radiation pattern resembles to the azimuth radiation pattern of monopole [7]. The reader almost equally radiates electromagnetic field for all angles. However, the reader radiates the lowest power at about 110° to the receiver. The power and signal cables in the back of the PCB, as shown in Figure 2, might cause the power drop at this angle.

The solid line in Figure 6 illustrates the normalized polar plot of E-field in E-plane. From Figure 6 suggests that the radiation pattern resembles the elevation radiation pattern of monopole antenna, that is it radiate most power in one side of the antenna. It can be also seen that the reader radiates most of the total power when it is rotated about 160° with respect to the horn antenna. In other words, it radiates most power from the top right corner of the reader. The directivity of this antenna can be obtained from this equation

$$D = \frac{P(\theta,\phi)_{\max}}{P(\theta,\phi)_{ave}}$$

where $P(\theta,\phi)_{\max}$ is the maximum power pattern and $P(\theta,\phi)_{\text{ave}}$ is the average radiation power pattern. From the measured radiation pattern, the directivity is 3.67 dB

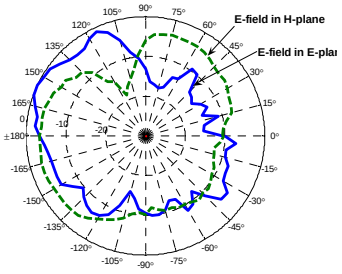

Figure 6. Radiation pattern of total E field in H plane and E Plane from testing in anechoic chamber

B. *Simulation Results*

While testing in anechoic chamber is the best way to obtain the realistic radiation patterns, it is expensive and time consuming process. If full wave electromagnetic simulation software is available, the radiation pattern can be obtained by the simulation. By using in house FDTD software, we can obtain the radiated pattern of the reader antenna. Figure 7 displays radiation pattern of E-field in E-plane and H-plane, respectively.

From the simulation, the radiation patterns form both azimuth and elevator resemble to those from the theoretical model of a dipole antenna [7]. The result is different from the measured radiation pattern since the simulation does not include the effect from other electronic components and other metal parts in the reader. However, the direction of maximum radiating power is similar to the measured radiation pattern.

IV. FIELD TEST

We propose a technique to determine the best position for the reader in the actual installation with knowledge of radiation patterns. The radiation patterns help to determine the initial set up of the reader and it will reduce the number of experiments in the actual installation. However, this method is also valid when the radiation pattern is not available but it will require more number of experiments.

A. *Experimental Setting*

A field experiment has been performed on an actual road in front of National Electronics and Computer Technology Center (NECTEC) building. The experiment consists of two main cases: 1) readability of tags when the reader placement at its highest and lowest radiated power, and 2) readability of tags when attached the reader to side of wall or pole.

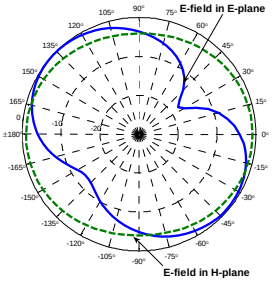

Figure 7. Radiation pattern of Total E field in H plane and E plane from simulation

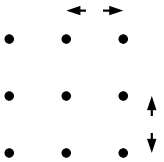

Figure 8. Grid of reader station at one measurement

In each measurement, the reader locates half wavelength space on the grid as shown in figure 8, which was 6.25 cm in this case. This type of measurement commonly uses to characterize both the small-scale and the large-scale statistics of the channel [6]. We repeated each measurement 180 times. The placement of the first test is based on the radiation patterns from in Section III. We installed the reader with the best direction (to place the top right corner of the reader faced down to the windshield of the vehicle as shown in Figure 9a). The reader station is 3 m high. We have measured the reading-range for 10 and 15 m. Then, we compare the results from the worst direction of reader to the tags. We also attach 7 tags on the windshield of vehicle to observe the best tags position on the windshield as shown in Figure 10.

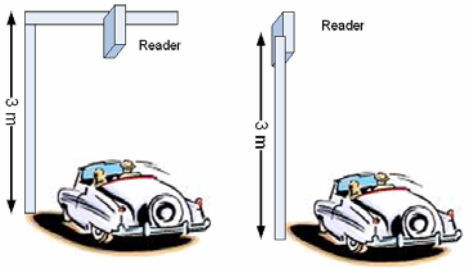

Figure 9 a) Field test the first case, b) Field test the second case

In the second test, we have attached the reader next to the pole at the height of 3 m from the floor, as shown in Figure 9b, and facing the front of the reader to the road. Then, we compare the results of the readability of tag when the reader is rotated with 30° increasing step with respect to the pole. In every measurement, the vehicle is located 10 m away from the reader station. At the same time, we also observe the best tags location on windshield of the vehicle by attaching seven tags on the windshield.

B. *Results*

The results from the first test are shown in Table 1. At 10 m, while the average readability of the best direction was

97.06%, the average readability of worst direction was 53.34%. As the distance between reader and tags is increased to 15 m, the readability of the worst direction deteriorates to 1.43 % while there was still 80% chance of reading the tag in the best direction.

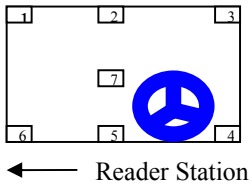

Figure 10 Tags positions on the windshield.

When the reader position is set to radiate maximum power to the tags according to the radiation pattern at the distance of 10 m, the readability is insensitive to the tag position. All tags can be read more than 90%. When the distance between the reader station and vehicle is increased to 15 m, the readability of tag is affected by tag position. Tag 1 gives the best performance while tag 5 gives the worst performance. In the worst radiating direction, only tag 1,3,6,7 can be read more than 50% and most tags cannot be read when the distance is 15 m.

TABLE 1 READABILITY OF EACH TAG IN FIRST CASE

Tag	Readability in best direction (%)		Readability in worse direction (%)	
	10 m	15 m	10 m	15 m
1	100	98.89	80	3.89
2	93.89	92.78	49	0
3	98.89	81.11	80	0
4	100	88.89	38.89	1.11
5	97.22	16.11	13.8	0
6	98.33	95	56.67	0
7	91.11	90	55	5
Ave	97.06	80.40	53.33	1.43

The results from the second test are shown in Table 2. The results suggest that the readability of tag has increased as we rotate the reader towards the car. The average readability reaches the peak at the angle of 120°, and then starts to decline at the angle 150°. These results are consistent with the radiation pattern in E-plane in Section III.

In terms of the tag position on the windshield of the vehicle, tag 4 outperformed the rest. Tag 1 and 6 were the second best. On the other hand, tag 5 provided the worst performance.

V. SUMMARY

Most specifications of RFID products provide the reading range for the ideal case, which is not suitable for the actual application. Besides, there is no information about the reader or tag radiation pattern that will help installation to obtain the most effective performance from the equipment. By testing in the anechoic chamber, we can obtain radiation patterns. However, this kind of test is often too expensive. Full wave simulation of the antenna is an alternative method for obtaining the radiation patterns. When the radiation patterns are known, the best orientation of the reader can be determined. We also perform readability tests when the reader is installed in the typical environment without any knowledge of radiation patterns. The results suggest that by increasing the tilt angle of the reader in respect to the pole towards the vehicle, the average readability is increased and the best orientation can be obtained. The best angle for readers in the field test is also consistent with the radiation pattern in H-plane from the anechoic chamber. The radiation patterns from simulation can also be utilized to estimate the best angle. Although, the radiation patterns from the simulation are not exactly the same as the radiation pattern from the anechoic chamber test, this information can be used to reduce number of experiments in the field test.

In terms of tags position, results show that the closest tags to the reader station do not always provide the best performance. This may cause by the surrounding environment or even the type of the vehicle. However, from the test, the nearest tags do provide the second best performance. This brings to another intrigue issue to find the relationship between the position of tag on windshield and the type of vehicle which will be further investigated.

The usability of active RFID equipments on the road access service is highly possible with some limitations on the tag and reader placement for the best performance. The readability of tags will perform differently in diverse environments and at the different vehicle speeds. Hence, it is always recommended to test practically in actual conditions before making the final decision.

TABLE 2 READABILITY OF EACH TAG IN SECOND CASE

Tag / °	1 (%)	2 (%)	3 (%)	4 (%)	5 (%)	6 (%)	7 (%)	Ave (%)
0	29	17	43	87	4	26	1	27
30	100	97	99	100	53	97	41	75

***Abstract*--Different types of media such as hard disk, flash drive and memory card require different memory formats. File Allocation Table (FAT) file system is ideal for use with devices that are optimized for quick media removal. FAT16 is a common file system for Windows family of operating systems in hard disk and also in removable media. When transferring data from hard disk to other types of media, the memory format of hard disk must be preserved. Even though the typical memory card size of RFID handheld reader is small (512MB or less), it must preserve the file system format of the hard disk and thus reduces the storage capacity. Different memory space will be allocated when not only identification number, but also with additional information is recorded for the RFID offline handling purpose. Based on the understanding of how data are recorded with FAT16, RFID users can benefit the most from the limited memory capacity in removable media. This paper aims to inform RFID users with options on recording data into the removable media with the adjustment regarding the number of identified items and any related information to the items.**

***Index Terms*—handheld RFID, removable media, FAT**

I. INTRODUCTION

Recently, Radio Frequency Identification (RFID) has been the topic of interest within both academic and industry domains [1]. RFID system consists of three major components: reader, transponder (tag) and data server. The communication between tag and reader uses a defined radio frequency protocol transmitted through signals as shown in Figure 1. Applications of RFID range from systems such as animal identification, access control, to supply-chain management. Employing RFID technology is considered a good approach in automated identification of products, with the prospect that tags could eventually replace barcode used ubiquitously at present. Comparing to barcode, RFID provides better reading range, requires no line-of-sight, and allows multiple products to be read simultaneously. RFID reader has two types: stationary and handheld. A stationary reader is fixed at a read location while handheld can move to anywhere. Handheld RFID reader records data into its internal memory or removable media. A cable is a mean to transfer recorded data in the internal memory to personal computer (PC), but a cable is not necessary when transferring data from a removable media to PC.

In order to transfer data from the removable media into the hard disk of a PC, the memory format FAT must also be transferred along with the data. In addition to the format, data will be arranged in the removable media according to the standard of FAT file system. Currently there are three FAT file system types: FAT12, FAT16, and FAT32. The FAT file system is ideal for removable media that is used in consumer electronic devices, such as digital cameras, media players, Flash drives and so on. FAT12 is, of course, the only file system that can be used on floppy disks. Windows supports FAT16 and FAT32 for hard disk volumes and removable media [2]. For the simplification of the process, the researchers begin with the implementation of the FAT16 on the removable media instead of FAT32. The concept of optimization records is always the goal of application developer; Sandisk released an application note on optimization of CF Host Operation for improve the read performance [3]. This paper applies this similar concept to optimize memory space for each RFID data types and its related information.

Anatomy of FAT16 file system

File Allocation Table (FAT) 16 structure information consists of 6 parts: (1) *Master Boot Record (MBR)* (2) *Volume ID* or *Boot Sector* (3) *Reserved Sector* (4) *FAT1*, *FAT2* (5) *Files and Directories* and (6) *Data Region* [3]. Each part is used for locating data in the file system.

Master Boot Record (MBR)

A *Master Boot Record* (MBR) is the first sector in memory (first 512 bytes). It contains a Boot Code area and partition information area accommodating up to four partitions as displayed in Figure 2. The first 446 out of 512 bytes in the MBR are assigned to the Boot Code area**.** This code is primarily used only for booting a computer from a hard disk. In case of removable media, all data in the Boot Code area is set to 0x00 because a boot code is not required. Taking up 16 bytes each, Partition 1 to Partition 4 contain data indicating the Starting Sector (SS) locations and the numbers of sectors in corresponding partitions. SS can also be referred to as the location of *Volume ID.* A memory card usually contains one partition whose information is stored in Partition 1, and Partition 2 -4 contain no data or 0x00. Next to these four partitions is the *footer* with 2-byte memory consisting of 0x55 and 0xAA. All data in the MBR area is very important because if this area is damaged, all data in the memory card will be unreadable.

Volume ID or Boot Sector

Volume ID consists of one sector with many details such as Bytes per Sector, Sector per Cluster, Number of Reserved Sector, Number of FAT, Maximum Root Directory Entries,

and Sectors per FAT. Volume ID is often the starting sector in the FAT layout system shown in Figure 3.

Reserved Sector

This area is reserved for operating systems other than windows such as DOS and OS/2 for the purpose of compatibility. In removable media, the number of sectors reserved will be indicated by the field in the Boot sector.

FAT1, FAT2

FAT1 and FAT2 hold information about cluster locations and how to connect data from these clusters together. To locate

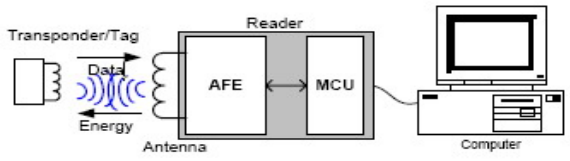

Figure 1. RFID system

FAT1, we must add the number of reserved sector in Volume ID to Starting Sector (SS) as shown in the Eq.2.

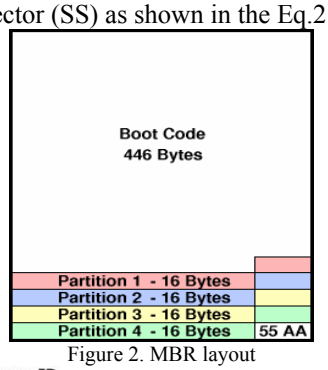

Figure 2. MBR layout

A N I M A L . . z .

Figure 7. Data structure with a folder name

Then, the location of FAT2 can be calculated by adding the value of Sector per FAT (SPF) to FAT1. Both data format and memory in FAT1 are the same as in FAT2.

Data inside FAT will be grouped into clusters. A cluster contains data in hexadecimal format. Cluster #0 and #1 are pre-determined by the type of media and partition state displayed in Figure 4. Next, Cluster #2 indicates the location of the next cluster that contains the data but if Cluster # 2 contains FFFF, this indicates the end of data in that cluster.

$$\text{Volume ID Starting location} = SS \quad (1)$$

$$\text{FAT1 Starting location} = SS + Res \quad (2)$$

$$\text{FAT2 Starting location} = SS + Res + SPF \quad (3)$$

$$\text{Files and Directory Starting Location} = SS + Res + (2*SPF) \quad (4)$$

$$\text{Data Region Starting location} = SS + Res + (2*SPF) + \ldots + ((MRDE*32)/BPS) \quad (5)$$

SS = Starting Sector, Res = Reserved, SPF = Sector per FAT,
MRDE = Maximum Root Directory Entries, BPS = Bytes per Sector

Here is an example of setting SS equal five. This number "five" behaves as a pointer to indicate the Volume ID sector. This sector #5 contains all information of Volume ID such as Bytes per Sector, Sector per Cluster, Number of Reserved Sector, Root entries, and Sectors per FAT. This information will further be used to calculate the starting sector of FAT1 and FAT2 as in Eqs.2-3. The number of sectors used up for FAT memory space is limited by Sector per FAT in the field of Volume ID. Next, it is possible to identify the starting location of Files and Directory and Data Region by Eqs.4-5 using information retrieved from the data in Volume ID as well.

Files and Directories

Information in FAT indicates the location of Files and Directory. When the first sector location of a file or a directory is known, the next step is to use data in the cluster fields of FAT to link data between sectors. An entry in File and Directories area contains 32 bytes. The first 8 bytes of memory in the sector are translated to the name of file in ASCII. Another 3 of 8 bytes is the extension file name. The next 5 bytes and 16 bytes are information of time stamp for modification of time and date as shown in Figure 5. The name of the recorded file is set to follow the short filename format of 8 characters only for simplification. The file extension ".txt" or "0x54 0x58 0x54" in the record is an example shown in Figure 6. For data recording in the directory (folder), the data in the extension field of 3 bytes will contain 0x20 0x20 and 0x20 indicating that it is not a file but a folder instead as shown in Figure 7.

Data Region

This area contains data records inside the sectors. The capacity of sector will be indicated in the *Volume ID* as Bytes per

Ssector. The starting location of data region can also be calculated using Eq. 5. The location of the data region must follow the files and directories area as in Figure 3.

II. RFID DATA RECORDS IN FAT16 FILE SYSTEM

In an RFID handheld reader, two main alternatives to record data in a removable medium are such that recording all information of an item into a file, or recording only the unique numbers of items into a file and leave other information to database server.

1. One ID in one file (OID)

This alternative is the simplest format for recording. Each file contains only one ID and that file has enough memory space for recording information associated with that ID. The only disadvantage is that it creates many storage files and requires extra time to locate each ID. One possible use of OID is to update the status of an animal such as feeding time and amount in the farm management application. Farm labor can update information through RFID handheld reader by typing information from the handheld keyboard and saving it to the memory card. It is necessary to reserve an equal capacity of each file to guarantee enough memory space. Typically, not all recorded files require the same memory resulting in inefficient memory utilization. Searching for an ID must follow the procedure for locating data from Eqs.1- 5 in the previous section. This procedure will be repeated in each file. This alternative is suitable for acquiring detailed information of an item in addition to an ID. To store this information in limited memory, a memory card can only save small numbers of items. Human involvement is necessary in the process of updating the information for often status changes of an item on the site.

2. Many IDs in one file (MID)

This alternative is for collecting only ID information so it is possible to include more IDs in the memory card than the OID alternative. There is only one file recorded in MID. Searching an ID is also a faster process because MID requires a locating procedure once for only one file in the card. Memory capacity of the card is used sufficiently. Only ID number is recorded and thus there is not enough information to decipher these ID numbers unless connecting to the data server. Limited information is suitable when only checking IDs is required. This is a typical recording format in the present. Majority of RFID handler associates RFID usage to replace a barcode system because of its unique number and non-line-of-sight advantage. Only ID is important for tracking the status of such application and RFID handheld reader will be less expensive when the function of keying update information is not required. This is useful for application that needs no human involvement for updating information. MID alternative is suitable for storing as many IDs as possible in a limited memory of a removable media for the application with the first priority on the amounts of ID detection.

IV. CASE STUDIES OF DATA RECORD

RFID in livestock application identifies an animal with a unique number. For the purpose of comparison in this paper, we set the unique identification number to be 15 digits following the draft of animal ID in Thailand [4]. In this paper, we make an assumption to record 15 digits of Animal IDs separated into 3 digits of country, 2 digits of animal species, and the other 10 digits are the running number of the animal. In addition to 15-digit ID, an RFID handheld reader may also retrieve updated information by farm labor and records that information into the removable media. To record unique IDs of animal into a file called “animal.txt” previously shown as an example in Figure 6, the ASCII data will be recorded with the details of country code, animal code and running number of the animal as shown in Figure 8. A simple way to understand the data recording scheme is to discuss two recording alternatives with the following examples.

1. One ID in one file (OID)

To record each animal ID into a file, extra information for farm management will be added to the previously stored information into the continuous sectors shown in Figure 9. As an example, the first ID is saved into the file “animal01.txt” while the second ID is saved into the file “animal02.txt”. The detailed of FAT system for this structure is displayed in Figure 10. Although equal memory capacity is reserved for all files but information saved in the file can be different so number of sectors used to record data will also be different.

Details in the “animal01.txt” file are country code, animal code and running number of animal and extra information of day month year to record this ID as shown in Figure 11. The left part of the figure indicates the ASCII data in the recorded sectors. To explain this ASCII data, the right part of the figure is shown only for comparison purpose for animal ID of 764091111111111 and date of record on 07/01/29 or January 29, 2007. Details in the “animal02.txt” file are country code, animal code and running number of animal and extra information of quantity of food as shown in Figure 12.

2. Many ID in one file (MID)

Figure 13 specifies three ID sample records in both ASCII data and also the 15 digit information for explanation. The ASCII data is the exact record in the FAT16 system. MID recording scheme can record many IDs into only one file which simplifies ID locating procedure from locating volume ID, Reserved, FAT1 FAT2, File and Directories and Data Region in Figure 10 only for one file. In the case of many files in OID, this procedure must be repeated for every file.

Combination of OID and MID might be used for utilizing the memory capacity in the memory card. Given the memory card with capacity of 1 gigabyte, and unique identification number of an animal is 15 bytes, it is possible to make decision on number of files and memory of bytes per file utilizing the memory capacity in the card. We assume that a file takes the space of a whole cluster, which contains multiple sectors of size 512 Bytes. For newer versions of Windows from Windows2000, the possible numbers of sectors in a cluster must be in the set $\{2^n: 0 \le n \le 7\}$. Furthermore, the maximum number of clusters for FAT16 is $2^{16} = 65{,}536$. Based on this information, we would like to identify appropriate the number of sectors per cluster so that a fifteen-byte identification

number with the following data can be stored efficiently in a 1 Gigabyte memory card: date (6 bytes), quantity of feed in kg. (2 bytes), and premises ID (13 bytes). Therefore, an entry of record would occupy 15 + 6 +2 + 13 = 36 bytes. We first investigate all possible numbers of sector by creating the data table. From Table 1, one can see that the number of sector per cluster must be in the set $\{2^n: 5 \le n \le 7\}$; otherwise, the number of cluster would exceed the number specified (2^{16} = 65,536). Maximum number of entries in a file will be the number of cluster divided by the entry size. The number of entries per file from this process is not always the integer number, in case of the decimal number, it must be rounded down. The decimal fraction reflects the memory that cannot store a complete record and is considered wasted. The exact number of used memory is the rounded number multiplied by the size of one entry record. It is possible to see the wasted memory in a cluster by comparing the available memory BPC in Table1 with the used BPC shown in Table 2. To utilize the capacity for the most entries of ID records of 15 bytes with least memory waste, the number of sector per cluster must be set to $\{2^n: n = 7\}$ for the number of files or total clusters of 16384, while this cluster utilization for an entry of 36 bytes creates the same result in number of entries. One can decide on the most number of clusters instead for the purpose of file categorization.

V. CONCLUSION

In this paper, we specified two options of data recording: One ID One file (OID) and Many IDs One File (MID). OID is an option for handling offline information very often. Additional information such as date and premises are commonly reserved for updating the status in the central database system. This option is suitable only for limited numbers of data entries to be identified because memory space must be reserved in advance. While MID is an option for only IDs requirement from multiple entries and this option simplifies the ID search within one file in contrast to the OID option that must search many files before finding an ID. This characteristic of each option implies the OID is appropriate for an application with low speed and small data such as animal identification, but MID will be more appropriate for an application with high speed and high data such as item identification in the warehouse. Utilizing memory in the memory card requires decision from RFID user. User can obtain the most benefit from removable media when user can identify the characteristics of the data required for each application.

***Abstract*-Paging extensions for Mobile Internet Protocol (P-MIP) only reduces the number of registrations in Mobile Internet Protocol (Mobile IP). P-MIP still uses similar registration procedure of Mobile IP which has high number of lost packets and long handoff latency if the distance between the Mobile Node and Home Agent is large. In this paper, we propose to combine P-MIP, Mobile IP Regional Registration, and multicasting to improve the performance of P-MIP. Simulation results show that the proposed method can reduce the signaling cost, the number of lost packets, and handoff latency of original P-MIP significantly.**

I. INTRODUCTION

Mobile Internet Protocol (Mobile IP) [1] is a proposal from Internet Engineering Task Force to support internet in mobile and wireless devices. Mobile IP assigns two IP addresses to Mobile Node (MN): Home Address which is assigned by the Home Agent (HA) in the home network and Care-of Address (CoA) which is assigned by a Foreign Agent (FA) in the foreign network. CoA is updated every time the MN changes its network. The MN detects whether it has changed its network by checking the Agent Advertisement message that is sent periodically by every FA. Whenever it moves to a new network, the MN registers to the HA through the present FA. When there is a node called Correspondent Node (CN) wants to send data to the MN, it must first send data to the HA. The HA then forwards the data to the MN through the latest FA.

As the basic protocol for mobile internet, Mobile IP still suffers a lot of problems, e.g. security, handoff latency, encapsulation overhead, triangle routing, and signaling load [1]. Paging Extensions for Mobile IP (P-MIP) [2] is one of the proposals that improve the performance of Mobile IP. P-MIP differentiates the state of the MN, which can be active or idle. An active MN is a MN which has just sent or received data. P-MIP uses paging to handle the location management of an idle MN. The wireless system uses paging procedure to search an idle MN when there is a message for that MN. Here, an idle MN does not need to register its precise location to the system whenever it moves. Paging decreases the signaling overhead related to registration and location system database updates. Paging also reduces the power consumption of the MN since the idle MN does not need to register with the system whenever it roams. However, P-MIP only concentrates to reduce the number of registrations and still uses the same registration method as Mobile IP, in which the registration may have long handoff latency and high number of lost packets if the distance between the MN and the HA is large.

In this paper, we propose to enhance the performance of P-MIP in terms of the number of lost packets and handoff latency. We use regional registration so that the MN does not need to register to the HA if it moves to the new network. We employ Protocol Independent Multicast-Sparse Mode multicast protocol [3] to send the data packets from Gateway Foreign Agent (GFA) to the FAs in the vicinity of the MN to make the MN able to accept the packets as soon as possible after handoff.

Several works have been done related to our work. Ref. [4] improved the performance of P-MIP by combining it with Mobile IP Regional Registration [5]. Ref. [6] combined P-MIP and Mobile IP Post Registration to reduce the number of lost packets and handoff latency of P-MIP. Ref. [7] has proposed Multicast for Mobility Protocol (MMP) which utilizes Core Based Trees multicast protocol in local domain to provide efficient location management and routing for the MN.

This paper is structured as follows. Section II discusses about the overview of P-MIP, Mobile IP Regional Registration, P-MIP Regional Registration, and P-MIP Post Registration methods. Section III explains our proposed method which is applied during MN's active time. Section IV presents the performance evaluation. Finally, section V concludes this paper and gives explanations of our future work.

II. OVERVIEW OF PAGING EXTENSIONS FOR MOBILE IP, MOBILE IP REGIONAL REGISTRATION, PAGING MOBILE IP REGIONAL REGISTRATION, AND PAGING MOBILE IP WITH POST REGISTRATION METHODS

A. Paging Extensions for Mobile IP (P-MIP)

Two or more networks construct a paging area in P-MIP. P-MIP extends the Agent Advertisement message in Mobile IP to contain a "P" bit to support paging. An active MN has to register to HA whenever it moves to a new network. In contrast, an idle MN does not need to register in the same situation and only registers when it changes its paging area or if there is data destined for that MN. If a CN wants to send packets to the MN, it will send them to the HA. The HA then delivers the packets to the registered FA. The registered FA first finds whether it has any information in the record for the MN. If a record exists, then that FA checks the operational state of the MN. If the MN is active, the FA forwards the packets to the MN. If the MN is

idle, the registered FA sends Paging Request messages to all other FAs that reside in the same paging area, as well as broadcasts the Paging Request on its own network. When the idle MN which has moved to another network receives that message, it registers with the HA through the current FA. After receiving Registration Reply message, the MN sends Paging Reply message to the registered FA through the present FA to inform its new location. After the registered FA receives Paging Reply message, that FA forwards any buffered packets toward the MN through the present FA. The incoming packets from the HA are then forwarded to the MN via present FA.

B. Mobile IP Regional Registration

In Mobile IP, the MN registers to the HA every time the MN changes its network. This causes high signaling load and long signaling delay during registration if the distance between MN and HA is large. Mobile IP Regional Registration [5] solves this problem by introducing a new entity called Gateway Foreign Agent (GFA). GFA is a local administrator for some FAs. When moving from one network to another within the same GFA, the MN does not need to register to the HA. Instead, the MN performs regional registration with the GFA by using a pair of registration messages. Regional Registration Request and Regional Registration Reply messages are used locally within a domain by the MN, the FAs, and GFA for regional registration. Mobile IP Regional Registration can reduce the signaling load and delay significantly. This also means that Mobile IP Regional Registration has lower number of lost packets and handoff latency than Mobile IP.

C. Paging Mobile IP Regional Registration

Ref. [4] proposed to combine P-MIP and Mobile IP Regional Registration. In this scheme, when there are packets for the MN, the HA sends the packets to the GFA. The GFA then checks the operational state of the MN. If it is active, the GFA encapsulates the packets and forwards them to present FA. The FA then delivers the packets to the MN. If the MN is idle, the GFA buffers incoming packets and sends Paging Request messages to all FAs that reside in the same paging area under that GFA. When the MN receives the Paging Request message, it registers to the GFA through the current FA. After receiving the Regional Registration Reply message, the MN sends a Paging Reply message to the GFA. Finally, the GFA sends the buffered and incoming packets to the MN.

D. Paging Mobile IP Post Registration

Ref. [6] improved the performance of P-MIP by using the idea of Mobile IP Post-Registration. Registration delay method is proposed in two phases, i.e. when the MN is active and when there are incoming data packets for the MN. Post-Registration scheme is used during active state to reduce the movement detection time. In P-MIP, the movement is detected when the MN receives Agent Advertisement message in Network Layer (Layer 3) periodically every one second. Using the Post-Registration method, the MN can detect that it has moved to another FA area fast since the MN uses Link Layer beacons which are sent every 100 ms to detect the movement.

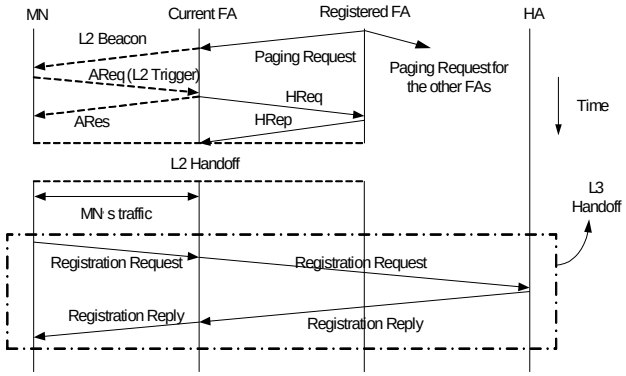

Figure 1. Signaling time diagram while the Mobile Node is entering the active state in [6].

When there are packets destined to the MN, the MN defers the registration process and keeps using the registered FA's CoA while the MN is on the current FA's subnet through the Bi-directional Edge Tunnel (BET). The BET is established between the registered FA and the current FA. Then, the MN can receive these packets fast before the MN registers to the HA. Fig. 1 shows the signaling time diagram of this work while the MN is entering the active state.

III. PROPOSED METHOD

P-MIP reduces the signaling load and power consumption in Mobile IP but still has high number of lost packets and long handoff latency. In this paper, we propose to combine P-MIP, Mobile IP Regional Registration, and multicasting to improve the performance of P-MIP. We use regional registration so that the active MN does not need to report to HA every time it moves to the new network. We employ Protocol Independent Multicast-Sparse Mode [3] to send packets from GFA to FAs in the vicinity of the MN to make the MN able to accept the packets fast after the handoff process. Hierarchical topology of Mobile IP Regional Registration is used in our work. Some FAs are grouped into two or more paging areas under the administration of one GFA. Non-overlapping paging area scheme is employed. The MN, the GFA and the FAs are assumed to support security, authentication, paging and multicasting. The hierarchical topology of the proposed method is shown in Fig. 2.

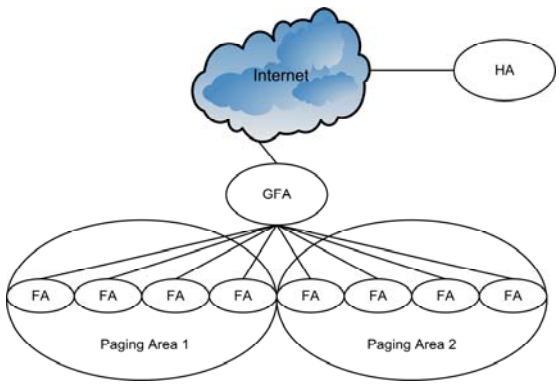

Figure 2. Hierarchical topology of the proposed method.

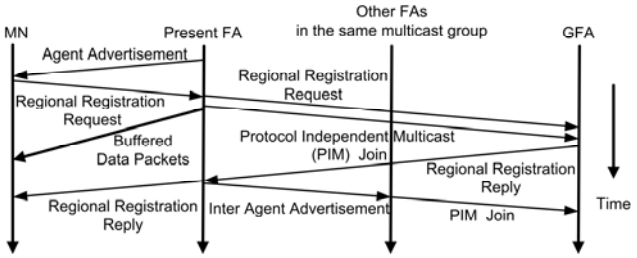

Figure 3. The signaling time diagram of regional registration of an active MN in the proposed method.

The MN is assigned with one multicast address within the GFA domain. Every FA broadcasts multicast addresses in the Agent Advertisement. The GFA uses the multicast address to multicast downlink data packets to FAs in the vicinity of an active MN. Multicasting is only applied locally within the GFA domain. If an active MN detects that it has moved to a new network, it conducts registration to the GFA. The MN uses Agent Advertisement for movement detection as in Ref. [2]. During registration, the multicast group and tree of the MN are constructed. After receiving Regional Registration Request message from the MN, the FA sends Protocol Independent Multicast (PIM) Join message to the GFA to form the multicast tree. The multicast group members are the FAs surrounding the present FA. The present FA constructs the multicast group by sending Inter-Agent Advertisement message to neighbor FAs every time the present FA receives Regional Registration Reply message from the GFA. The Inter-Agent Advertisement message contains the multicast address that neighbor FAs have to join. Neighbor FAs then join the multicast group by sending PIM Join message to the GFA. Fig. 3 shows the registration process of an active MN in the proposed method.

When there are data packets from the HA to the MN, the HA will first send the packets to the GFA. The GFA then checks the state of the MN. If the MN is in active state, the GFA multicasts the packets to the MN's multicast group. If the MN is in idle state, the GFA buffers the incoming packets and sends Paging Request messages to all FAs that reside in the last reported paging area visited by the MN. Every FA then broadcasts Paging Request message in its own area. When the idle MN receives the Paging Request message and finds that it is still located in the last registered FA, the MN sends Paging Reply message to the GFA and sets its state to be active. Otherwise, the MN conducts regional registration to GFA as explained in the previous paragraph. When the FA receives Regional Registration Reply message from the GFA, it sets the state of the MN to be active and relays the message to the MN. After receiving Regional Registration Reply message, the MN sends Paging Reply message to the GFA. The GFA then multicasts and forwards the buffered and incoming packets to the MN's multicast group. Present FA forwards the packets, while other FAs in the same multicast group buffer the packets and forward the packets as soon as the MN moves to their network. Fig. 4 shows the signaling time diagram when the HA sends packets to an idle MN in the proposed method.

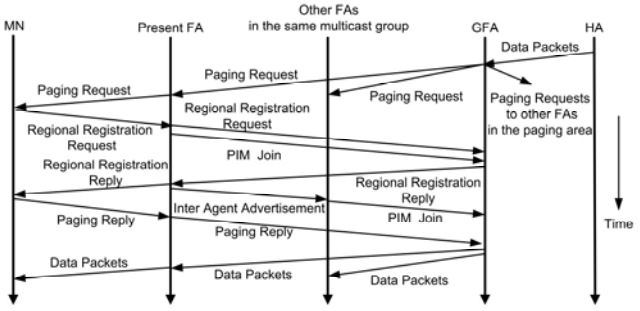

Figure 4. The signaling time diagram when the HA sends packets to an idle MN through the GFA in the proposed method.

IV. Performance Evaluation

We simulate Mobile IP, Paging Mobile IP, P-MIP Post Registration, P-MIP Regional Registration, and the proposed method using Borland Delphi 7.0. We adapt the network model in Ref. [6] in our simulation. HA sends Constant Bit Rate 500-bytes packets with 10 ms period as the traffic source. Wireless LAN 802.11 with 100 ms period of beacon is chosen to be the Link Layer. The FA broadcasts Agent Advertisement message every one second. There are two paging areas where both paging areas contain a number of cells. Each cell is associated with one FA in an overlapping cell scenario with 122 m diameter and 1 m overlapping area. We assumed that all links have 5 Mbps transmission rate and every link has 3 ms transmission delay. The active MN percentage is 5 % [2]. Protocol Independent Multicast-Sparse Mode [3] is used as multicasting protocol. We apply one GFA, one straight moving MN, and one HA in the simulation. We vary the speed of the MN and the number of hops between the GFA and the HA to evaluate the signaling cost, handoff latency, and the number of lost packets. Fig. 5 shows the simulation model.

In Fig. 6, we show the impact of MN's speed on signaling cost. There are 50 cells in one paging area. The number of hops between GFA and HA is set to be 40. The duration of the simulation is 342.259 s. There are three time periods. Every period lasts for 112 s. There are 95 % of idle time and 5 % of active time for the MN in one period.

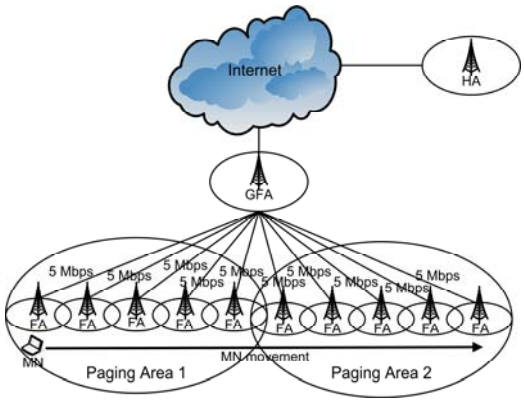

Figure 5. Simulation model with overlapping cell scenario.

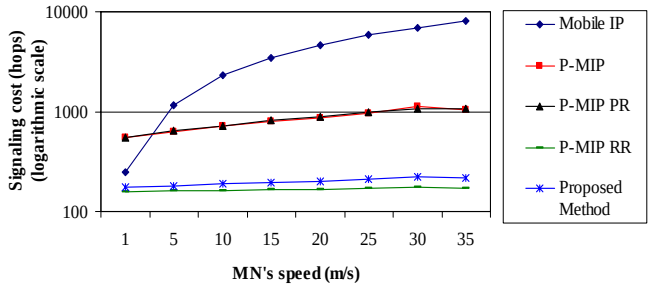

Figure 6. Signaling cost as the function of MN's speed.

Signaling cost of every method increases as the MN's speed increases. It is because of more cell boundary crossings and more registrations at higher MN's speed. The signaling cost of the proposed method is much lower than that of Mobile IP, P-MIP, and P-MIP Post Registration (P-MIP PR) since the MN only registers to the GFA and not to the far away HA. However, the signaling cost of our method is a little bit higher than that of P-MIP Regional Registration (P-MIP RR) because of increased signaling cost of the multicasting messages.

With the same model parameters, we investigate the handoff latency and the number of lost packets as shown in Fig. 7 and Fig 8. In overall, the handoff latency and the number of lost packets depend on the movement detection used by each method. P-MIP PR has the best performance since it uses Link Layer for movement detection, whereas the other methods use Network Layer (i.e. use Agent Advertisement that is broadcast every 1 second). However, the proposed method has lower handoff latency and the number of lost packets than Mobile IP, P-MIP, and P-MIP RR. It is because the MN can reduce the signaling delay by conducting regional registration to the GFA. Moreover, the MN can receive the packets fast since the present FA forwards the buffered packets to the MN after it receives Regional Registration Request message from the MN.

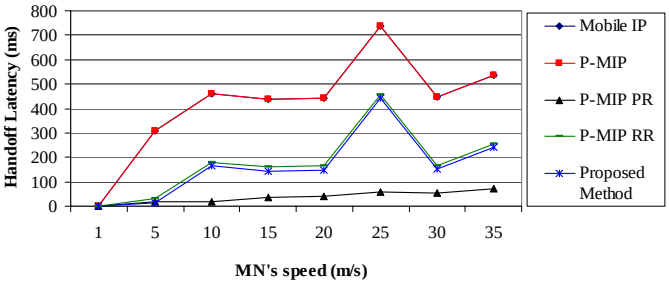

Figure 7. Handoff latency as the function of MN's speed.

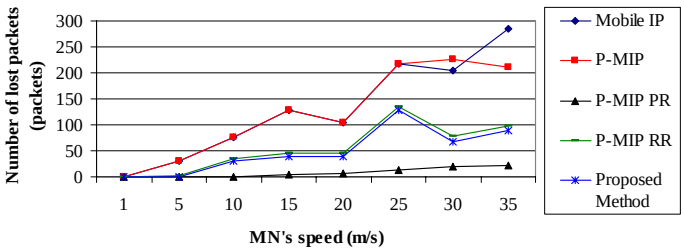

Figure 8. The number of lost packets as the function of MN's speed.

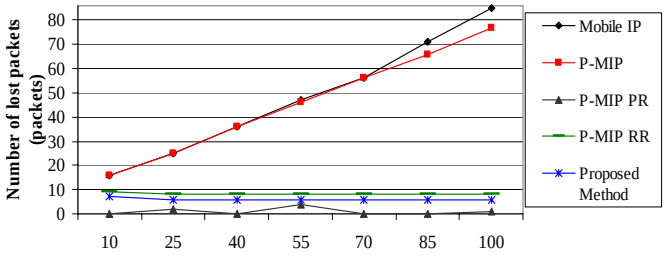

Figure 9. The number of lost packets as the function of the number of hops between GFA and HA.

We vary the number of hops between GFA and HA to see the impact on the number of lost packets. The parameters are 15 cells in a paging area, 15 m/s of the MN's speed, and one period of data with 233.934 s of simulation time. As we can see from Fig. 9, the number of lost packets in the proposed method and P-MIP RR are not influenced by the number of hops. It is not similar to Mobile IP and P-MIP where the registration messages to the HA have to experience longer delay if the number of hops between GFA and HA is increased. P-MIP PR is also not influenced by the number of hops since it can defer the registration in Network Layer and use Link Layer registration so that it can accept data packets faster than the other methods.

V. Conclusion And Future Work

In this paper, we propose to combine P-MIP, regional registration, and multicasting to improve the performance of P-MIP. The simulation results show that the proposed method can reduce the signaling cost, handoff latency, and the number of lost packets of P-MIP. In the future, we will study how to apply Link Layer as the movement detection mechanism in the proposed method to make further improvement to the present results.

Adaptive Protocol with Channel Variance Estimations for Cooperative Communications

Chaiyod Pirak

***Abstract*— A cooperative communication system is one of prominent communication systems for the future wireless communications because it could provide a diversity gain achieved by the cooperation among users in the wireless network. In this paper, we propose a time-reversal technique for channel variance estimations, including a least square (LS), a modified LS, a minimum mean-square error (MMSE), and a modified MMSE estimations, for the proposed minimum symbol-error-rate (SER)-based adaptive protocol in the cooperative communication systems. Simulation results show that the proposed adaptive protocol with the modified LS estimation is the best scheme because it provides a closed SER to the ideal scheme with the lowest complexity.**

I. Introduction

Multiple-input multiple-output (MIMO) communication systems have been recognized as the communication scheme for the future wireless communications due to their diversity gain that results in a lower error probability. Recently, a generalized MIMO system called cooperative communication [1] has been proposed for realizing such diversity gain of the conventional MIMO system. By the cooperation of the active users equipped with a single antenna in the wireless networks, the generalized MIMO system can be established in a distributed fashion. In addition, the coverage range of such communication is also expanded, which results in less power consumption for a particular user who communicates with far-away destinations, and in turn prolongs a battery life.

Recently, various protocols have been proposed for the cooperation system [1], in which each user acts as a relay to assist other users transmit their information. A relay can either amplify the received signal and forward it, or decode the received signal first and then forward it. In addition, outage probability performance has been analyzed for such cooperation systems. The direct benefit of cooperatively working with more users is the diversity gain that comes at the price of the reduced transmission rate since the cooperation partners need to sacrifice their time slots for transmitting the source information. In [2], we proposed an adaptive protocol based on minimizing a tight approximate symbol error rate (SER). The proposed protocol can achieve the maximum achievable diversity gain in the system without sacrificing any transmission rate or total transmit power. In addition, this protocol is able to determine the best cooperation strategies in accordance with the changing environment. One of the most essential parameters needed for the source node to compute such approximate SER, used in the adaptation process, is a short-term channel variance. Previously, it was assumed known to the source node. In this paper, it is estimated through a pilot signal transmission. There has been studied that a pair of outgoing and incoming fading channels between a transmitter and a receiver is approximately reciprocal for slowly-varying channels [3]. Hence, we further exploit the reciprocity of slowly-varying fading channels to better estimate that of short-term channel variance using a time-reversal technique. The main contributions of this paper are as follows,

- We propose the time-reversal technique for channel variance estimations including a least square (LS) estimation, a modified LS estimation, a minimum mean-square error (MMSE) estimation, and a modified MMSE estimation.
- We numerically investigate the performance of the adaptive protocol with various kinds of channel variance estimations. We can show that the adaptive protocol with the modified LS estimation is the best scheme because its performance is close to the ideal scheme and its complexity is the lowest.

This paper is organized as follows. In Section II, we describe system models. In Section III, we describe a signal transmission in a transmission period. In Section IV, we propose a signal transmission in an acquisition period. The simulation results are shown in Section V, and we conclude this paper in Section VI.

II. Signal Transmission and System Models

For the sake of exposition, we consider cooperative communications in the wireless network with two phases, three users (i.e. one user acts as a source node and the other users act as relay nodes), and one destination. We consider the half-duplex communication system, i.e. a transceiver transmits or receives the signal in separate time slots, with two periods: an acquisition period and a transmission period. During the transmission period, the source and relay nodes cooperatively communicate with the destination. There are two transmission phases in this period. In Phase I, user 1 transmits a modulated signal to its destination, while user 2 and user 3 also receive this transmitted signal due to a broadcast nature of wireless channels. In Phase II, user 2 and user 3, or either of them relay the received signal to user 1's destination in an amplify-and-forward fashion. Likewise, in the next communication periods, user 2 and user 3 act as the source node, respectively, and the other users act as the relay nodes. In both phases, all users transmit signals through orthogonal channels by using a time-division multiple access (TDMA) scheme [1], [2], [4]. Due to the symmetry of the three users, we will analyze only user 1's performance by considering user 1 as the source node, user 2 as relay 1, and user 3 as relay 2. In this study, we employ an M-PSK modulation scheme. In order to maintain a fixed transmission rate, e.g. rate=1, an adaptive modulation scheme is considered. Specifically, for a

noncooperation strategy where no relay nodes are employed, BPSK modulation is used. For a 1-relay cooperation strategy where either relay 1 or relay 2 is employed, QPSK modulation is used. Finally, for a 2-relay cooperation strategy where both relay 1 and relay 2 are employed, 8-PSK modulation is used. In general, for an arbitrary transmission rate, the constellation of the adaptive modulation can be adjusted accordingly.

During the acquisition period, the source node determines the best cooperation partners by using a pilot-assisted technique in conjunction with a time-reversal technique described in Section IV. Then, the source node notifies the destination as well as the corresponding relay nodes about its cooperation strategy via some control channels. Here since we focus on a fixed transmission rate of 1, and there are 3 users in the cooperation system, the number of data packets in each transmission period with certain cooperation strategy must be in an order multiple of $6i,\ i \in \mathbb{I}$, so that all cooperation strategies' communications will be terminated at the end of the transmission period simultaneously. In addition, the total transmit power P per data packet is fixed for all cooperation strategies.

III. Signal Transmission in Transmission Period

In this section, we describe a signal transmission in the transmission period, including channel and signal models, a SER analysis, and the proposed asymptotic minimum SER-based adaptive protocol. In Phase I, the source node broadcasts its transmit signal to the destination and the relay nodes. The received signal z_{1B} at the destination, z_{12} at relay 1, and z_{13} at relay 2 can be expressed as follows,

$$z_{1B} = \sqrt{P_1} h_{1B} u + n_{1B}, \tag{1}$$

$$z_{12} = \sqrt{P_1} h_{12} u + n_{12}, \tag{2}$$

$$z_{13} = \sqrt{P_1} h_{13} u + n_{13}, \tag{3}$$

where P_1 is the transmit power of the source node; u is the transmitted symbol; $h_{1B}, h_{12},$ and h_{13} are the channel coefficients from the source to the destination, relay 1, and relay 2, respectively; and $n_{1B}, n_{12},$ and n_{13} are the additive noises modelled as zero-mean, complex Gaussian random variables with variance N_0. In Phase II, the relay nodes amplify the received signals and forward them to the destination with the transmit power $\tilde{P}_2$ and $\tilde{P}_3$ for relay 1 and relay 2, respectively. The received signal at the destination can be written as

$$y_{2B} = \frac{\sqrt{\tilde{P}_2}}{\sqrt{P_1|h_{12}|^2+N_0}} h_{2B} z_{12} + n_{2B}, \tag{4}$$

$$y_{3B} = \frac{\sqrt{\tilde{P}_3}}{\sqrt{P_1|h_{13}|^2+N_0}} h_{3B} z_{13} + n_{3B}, \tag{5}$$

$$\tilde{P}_2 = \begin{cases} 0; \text{ If relay 1 is not selected} \\ P_2; \text{ Otherwise.} \end{cases},$$

$$\tilde{P}_3 = \begin{cases} 0; \text{ If relay 2 is not selected} \\ P_3; \text{ Otherwise.} \end{cases},$$

where h_{2B} and h_{3B} are the channel coefficients from relay 1 and relay 2 to the destination, respectively; and n_{2B} and n_{3B} are also additive Gaussian noises with zero-mean and variance N_0. In addition, the channel coefficients $h_{1B}, h_{2B}, h_{3B}, h_{12}$, and h_{13} are modelled as slowly-varying Rayleigh fading channels with variances $\delta^2_{1B}, \delta^2_{2B}, \delta^2_{3B}, \delta^2_{12}$ and δ^2_{13}, respectively. These channel coefficients are assumed to be known to the destination node so that the maximum-ratio combining (MRC) [5] can be performed.

A. Symbol Error Rate Analysis

In this section, we derive an approximate SER for cooperation systems with the M-PSK modulation. The output of the MRC detector at the destination can be expressed as follows [5],

$$y = a_1 z_{1B} + a_2 y_{2B} + a_3 y_{3B}, \tag{6}$$

$$a_1 = \sqrt{P_1} h^*_{1B} / N_0,$$

$$a_2 = \begin{cases} 0; \text{ If relay 1 is not selected} \\ \dfrac{\sqrt{\frac{P_1 \tilde{P}_2}{P_1|h_{12}|^2+N_0}} h^*_{12} h^*_{2B}}{\left(\frac{\tilde{P}_2|h_{2B}|^2}{P_1|h_{12}|^2+N_0}+1\right) N_0}; \text{ Otherwise.} \end{cases},$$

$$a_3 = \begin{cases} 0; \text{ If relay 2 is not selected} \\ \dfrac{\sqrt{\frac{P_1 \tilde{P}_3}{P_1|h_{13}|^2+N_0}} h^*_{13} h^*_{3B}}{\left(\frac{\tilde{P}_3|h_{3B}|^2}{P_1|h_{13}|^2+N_0}+1\right) N_0}; \text{ Otherwise.} \end{cases}$$

Assuming that the transmitted symbol u has a unit average energy, then the approximate SNR of the MRC output can be written as follows [4], [5],

$$\gamma \approx \gamma_1 + \gamma_2 + \gamma_3, \tag{7}$$

where $\gamma_1 = P_1|h_{1B}|^2/N_0,\ \gamma_2 = \frac{P_1 \tilde{P}_2 |h_{12}|^2 |h_{2B}|^2}{N_0\left(P_1|h_{12}|^2+\tilde{P}_2|h_{2B}|^2\right)},\ \gamma_3 = \frac{P_1 \tilde{P}_3 |h_{13}|^2 |h_{3B}|^2}{N_0\left(P_1|h_{13}|^2+\tilde{P}_3|h_{3B}|^2\right)}$. Computing the conditional SER and averaging it over the Rayleigh fading channels [6], and using a tight upper bound on SER derived in [2], we can derive the approximate SER of such system as follows. First, for the noncooperation strategy, we can show that the approximate SER with the BPSK modulation can be written as,

$$P_{BPSK} \approx \frac{N_0}{4P\delta^2_{1B}}. \tag{8}$$

Second, for the 1-relay cooperation strategy where relay 1 is selected, we can show that the approximate SER with the QPSK modulation can be written as,

$$P^{relay\ 1}_{QPSK} \approx 4CN_0^2 \cdot \frac{P_1\delta^2_{12} + P_2\delta^2_{2B}}{P_1^2 P_2 \delta^2_{1B}\delta^2_{2B}\delta^2_{12}}, \tag{9}$$

where $C = \left[\frac{9}{32} + \frac{1}{4\pi}\right]$ and $P = P_1 + P_2$. Likewise, for the 1-relay cooperation strategy where the relay 2 is selected, we can show that the approximate SER with the QPSK modulation can be written as follows,

$$P^{relay\ 2}_{QPSK} \approx 4CN_0^2 \cdot \frac{P_1\delta^2_{13} + P_3\delta^2_{3B}}{P_1^2 P_3 \delta^2_{1B}\delta^2_{3B}\delta^2_{13}}, \tag{10}$$

where $P = P_1 + P_3$. Finally, for the 2-relay cooperation strategy, we can show that the approximate SER with the 8-PSK modulation can be written as,

$$P_{8PSK} \approx \frac{DN_0^3}{E} \cdot \frac{\left(P_1\delta^2_{12} + P_2\delta^2_{2B}\right)\left(P_1\delta^2_{13} + P_3\delta^2_{3B}\right)}{P_1^3 P_2 P_3 \delta^2_{1B}\delta^2_{2B}\delta^2_{3B}\delta^2_{12}\delta^2_{13}}, \tag{11}$$

where $D = \left[\frac{-13}{128} + \frac{23}{12\sqrt{2}}\right],\ E = \frac{1}{2}\left[1 - \frac{1}{\sqrt{2}}\right]$, and $P = P_1 + P_2 + P_3$.

B. The Asymptotic Minimum SER-based Adaptive Protocol

Now the most desirable protocol is the protocol that is able to achieve the asymptotic minimum error probability in an averaging sense under high-enough SNR regimes, expressed as

$$\arg \min_{\text{number \& index of cooperation partners}} Pr(error)$$
$$\text{s.t. fixed rate and total transmit power constraints.} \tag{12}$$

The procedures of the proposed adaptive protocol can be described as follows,

1) The source node acquires a short-term channel variances [5], i.e. $\delta^2_{1B}, \delta^2_{2B}, \delta^2_{3B}, \delta^2_{12}$, and δ^2_{13}, within the acquisition period described in the following section. This channel variances will be used as if they were the exact short-term channel variances during the upcoming transmission period given that the channel is slowly varying.
2) The source node calculates the approximate SER derived in Section III-A for such cooperation strategies, and then compares them all. The best cooperation strategy that results in the asymptotic minimum SER will be chosen for the upcoming transmission period.
3) The source node notifies the chosen cooperation partners and the destination about the cooperation strategy decision via some control channels.

IV. Signal Transmission in Acquisition Period

In this section, we propose the time-reversal approach for the instantaneous channel variance estimations. In this paper, we assume that each pair of inter-user channels is reciprocal, i.e. $h_{21} \approx h_{12}, h_{31} \approx h_{13}, h_{B1} \approx h_{1B}, h_{B2} \approx h_{2B}$, and $h_{B3} \approx h_{3B}$. This assumption is adequately consistent because the channels are slowly varying, resulting from slowly changing in each node's location [3]. In the acquisition period, all short-term channel variances, i.e. $\delta^2_{1B}, \delta^2_{2B}, \delta^2_{3B}, \delta^2_{12}$, and δ^2_{13}, are being estimated to be used in an adaptation process of the proposed adaptive protocol in Section III-B. We employ a time average approach for estimating such short-term channel variances, expressed as

$$\bar{\delta}^2_{ij} = \frac{1}{M}\sum_{k=1}^{M} |h^k_{ij}|^2, \ \exists i \in \{1,2,3\} \text{ and } \exists i \in \{2,3,B\}, \quad (13)$$

where M stands for a number of pilot blocks sent in this period and $|h^k_{ij}|^2$ denotes the k^{th}-block instantaneous channel variance of the sender node i and the receiver node j.

There are two transmission phases in this period. In Phase I, the instantaneous channel variances $|h_{12}|^2$ and $|h_{13}|^2$ are to be estimated at the source node. In Phase II, the instantaneous channel variances $|h_{1B}|^2, |h_{2B}|^2$ and $|h_{3B}|^2$ are to be estimated at the destination node. Then, they will be sent to the source node via the control channels. In Phase I-State I, the source node broadcasts the pilot signal, i.e. $u = 1$, to the destination and the relay nodes. The received signal z^I_{1B} at the destination, z^I_{12} at relay 1, and z^I_{13} at relay 2 can be expressed as follows,

$$z^I_{1B} = \sqrt{P_1} h_{1B} + n_{1B}, \quad (14)$$
$$z^I_{12} = \sqrt{P_1} h_{12} + n_{12}, \quad (15)$$
$$z^I_{13} = \sqrt{P_1} h_{13} + n_{13}, \quad (16)$$

In Phase I- State II and III, the relay nodes performs a time-reversal complex-conjugate mirror [3] by complex-conjugating the received signal. Then, this complex-conjugated received signal is amplified and forwarded to the destination by the relay 1 and relay 2, respectively. Due to the broadcast nature of wireless channels, this relayed signal also propagates back to the source node. The received signal at the source node can be written as

$$y^I_{21} = \frac{\sqrt{P_2}}{\sqrt{P_1|h_{12}|^2+N_0}} h_{21} z^{I*}_{12} + n_{21}, \quad (17)$$
$$y^I_{31} = \frac{\sqrt{P_3}}{\sqrt{P_1|h_{13}|^2+N_0}} h_{31} z^{I*}_{13} + n_{31}. \quad (18)$$

Substituting z^I_{12} and z^I_{13} in (15) and (16) into (17) and (18), respectively, to arrive at

$$y^I_{21} = \frac{\sqrt{P_1P_2}}{\sqrt{P_1|h_{12}|^2+N_0}} h_{21} h^*_{12} + \frac{\sqrt{P_2}}{\sqrt{P_1|h_{12}|^2+N_0}} n^*_{12} + n_{21}, \quad (19)$$
$$y^I_{31} = \frac{\sqrt{P_1P_3}}{\sqrt{P_1|h_{13}|^2+N_0}} h_{31} h^*_{13} + \frac{\sqrt{P_3}}{\sqrt{P_1|h_{13}|^2+N_0}} n^*_{13} + n_{31}. \quad (20)$$

By the assumption that the channels are reciprocal, i.e. $h_{21} \approx h_{12}$ and $h_{31} \approx h_{13}$, we have

$$y^I_{21} = \xi_{21}|h_{12}|^2 + \frac{\xi_{21}}{\sqrt{P_1}} n^*_{12} + n_{21}, \quad (21)$$
$$y^I_{31} = \xi_{31}|h_{13}|^2 + \frac{\xi_{31}}{\sqrt{P_1}} n^*_{13} + n_{31}, \quad (22)$$

where $\xi_{21} = \frac{\sqrt{P_1P_2}}{\sqrt{P_1|h_{12}|^2+N_0}}$ and $\xi_{31} = \frac{\sqrt{P_1P_3}}{\sqrt{P_1|h_{13}|^2+N_0}}$.

Similarly, in Phase II-State I, the destination node broadcasts the pilot signal to the source and the relay nodes with the power P. The received signal z^{II}_{B1} at the source, z^{II}_{B2} at relay 1, and z^{II}_{B3} at relay 2 can be expressed as follows,

$$z^{II}_{B1} = \sqrt{P} h_{B1} + n_{B1}, \quad (23)$$
$$z^{II}_{B2} = \sqrt{P} h_{B2} + n_{B2}, \quad (24)$$
$$z^{II}_{B3} = \sqrt{P} h_{B3} + n_{B3}, \quad (25)$$

In Phase II-State II-IV, the source and relay nodes perform a time-reversal complex-conjugate mirror to the received signal, and amplify and forward the resulting signal back to the destination, respectively. By the assumption that the channels are reciprocal, i.e. $h_{B1} \approx h_{1B}, h_{B2} \approx h_{2B}$ and $h_{B3} \approx h_{3B}$, we have

$$y^{II}_{1B} = \xi_{1B}|h_{1B}|^2 + \frac{\xi_{1B}}{\sqrt{P}} n^*_{1B} + n_{B1}, \quad (26)$$
$$y^{II}_{2B} = \xi_{2B}|h_{2B}|^2 + \frac{\xi_{2B}}{\sqrt{P}} n^*_{2B} + n_{B2}, \quad (27)$$
$$y^{II}_{3B} = \xi_{3B}|h_{3B}|^2 + \frac{\xi_{3B}}{\sqrt{P}} n^*_{3B} + n_{B3}, \quad (28)$$

where y^{II}_{1B}, y^{II}_{2B} and y^{II}_{3B} are the received signals transmitted from the source, relay 1, and relay 2 to the destination, respectively; and $\xi_{1B} = \frac{P}{\sqrt{P|h_{1B}|^2+N_0}}, \xi_{2B} = \frac{P}{\sqrt{P|h_{2B}|^2+N_0}}$ and $\xi_{3B} = \frac{P}{\sqrt{P|h_{3B}|^2+N_0}}$. Here, $n_{21}, n_{31}, n_{B1}, n_{B2}$ and n_{B3} are modelled as zero-mean, complex Gaussian random variables with variance N_0. Now we estimate the instantaneous channel variances $|h_{12}|^2, |h_{13}|^2, |h_{1B}|^2, |h_{2B}|^2$ and $|h_{3B}|^2$ from (21)-(22) and (26)-(28), respectively. For the sake of simplicity, we just only show the derivation of estimating $|h_{12}|^2$. The remaining ones can be estimated in the same way.

A. Least Square Estimation

The objective function for the LS estimation can be written as

$$\widehat{|h_{12}|^2}_{LS} = \arg\min_{|h_{12}|^2} \|y^I_{21} - \xi_{21}|h_{12}|^2\|^2. \quad (29)$$

After some algebraic manipulation, it can be shown that

$$\widehat{|h_{12}|^2}_{LS} = y^I_{21}/\xi_{21}. \quad (30)$$

From the fact that $|h_{12}|^2$ is a positive-value variable, we further propose the modified LS channel variance estimation by taking an absolute operator to (30), to arrive at

$$\widehat{|h_{12}|^2}_{MLS} = \left|y^I_{21}/\xi_{21}\right|. \quad (31)$$

B. Minimum Mean-Square Error Estimation

We employ a linear finite impulse response (FIR) filter, w_{12}, to estimate the channel variance as follows,

$$|h_{12}|^2 = w_{12} y^I_{21}. \quad (32)$$

The objective function for computing w_{12} is based on minimizing a mean-square error expressed as

$$w_{12} = \arg\min_{w} \mathrm{E}[\|\,|h_{12}|^2 - w y_{21}^I\|^2]. \quad (33)$$

After some algebraic manipulation and from the identity that $\mathrm{E}[\|\,|h_{12}|^2\|^2] = 2\delta_{12}^4$, we have

$$\widehat{|h_{12}|^2}_{MMSE} = \frac{y_{21}^I}{\xi_{21} + \beta}, \quad (34)$$

where $\beta = \frac{N_0(1+\xi_{21}^2/P_1)}{2\xi_{21}\delta_{12}^4}$. In a similar reason to Section IV-A, we further propose a modified MMSE channel variance estimation as follows,

$$\widehat{|h_{12}|^2}_{MMMSE} = \left| \frac{y_{21}^I}{\xi_{21} + \beta} \right|. \quad (35)$$

V. Simulation Results

In this section, based on simulations, performance evaluation of the proposed adaptive protocol employing the time-reversal channel variance estimations is carried out. Adaptive modulation with BPSK, QPSK, and 8-PSK constellations are employed. The total transmit power is fixed to be P=1 W, and the bandwidth efficiency is 1 bit/s/Hz. In addition, one acquisition period consists of 2 pilot blocks, i.e. $M = 2$, and one transmission period consists of 6 data packets so that all cooperation strategies' communications will be terminated at the end of the transmission period simultaneously. The channel variances are $\delta_{1B}^2 = 1, \delta_{2B}^2 = 1, \delta_{3B}^2 = 1, \delta_{12}^2 = 10$, and $\delta_{13}^2 = 5$. For a fair comparison, we illustrate the average SER curves as function of P/N_0.

In Fig.1, we show the average SER versus SNR(dB) for different cooperation strategies in quasi-static Rayleigh fading channels, i.e. the channels are constant over a pair of consecutive acquisition and transmission periods and change in a period-by-period basis, with a normalized Doppler shift $f_d T_s$ of 0.005 with f_d being the Doppler shift and T_s being the symbol duration. It turns out that the adaptive protocol with the modified LS and MMSE estimations yields the closed error probability to the ideal scheme, in which all channel variances are assumed to be known to the source node. This result suggests that the adaptive protocol with the modified LS estimation is the best scheme because its performance is close to the ideal scheme and its complexity is the lowest (see (31)). It is worth noticing that the proposed adaptive protocol achieves the maximum diversity of 3, and yields a remarkably lower SER.

In Fig.2, we show the MSE for the proposed time-reversal channel variance estimations in the source-destination link. It is worth noticing that the modified MMSE estimation yields the lowest MSE at the price of high computational complexity. In addition, because of the knowledge about the noise and channel variances, the MMSE estimations yield the lower MSEs than the LS estimations in low SNR regimes.

VI. Conclusion

In this paper, we have proposed the time-reversal technique for channel variance estimations, including the LS, modified LS, MMSE, and modified MMSE estimations, for the adaptive protocol in the cooperative communication systems. We have also proposed the signal transmission strategy for such systems. Simulation results indicated that the adaptive protocol with the modified LS and MMSE estimations yielded a remarkably lower SER that is close to the ideal scheme, in which a SNR difference of 0.5 dB at SER of 10^{-5} was observed. On the other hand, such

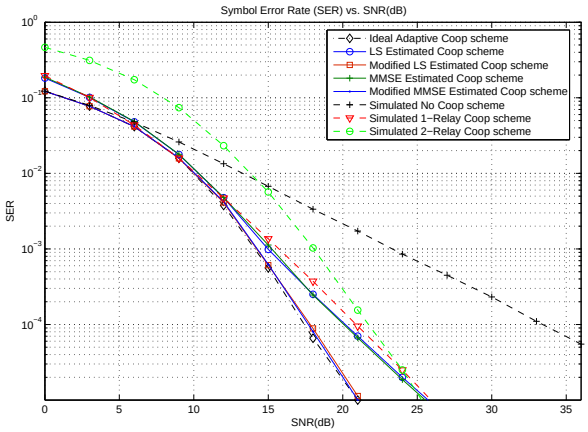

Fig. 1: The curves of the average SER for different cooperative protocols in quasi-static Rayleigh fading channels.

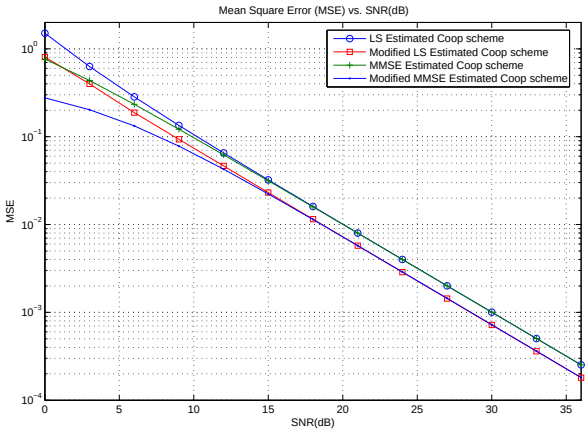

Fig. 2: The curves of the MSE for the proposed time-reversal channel variance estimations in the source-destination link.

protocol with the LS and MMSE estimations yielded the worst performance, in which a SNR difference of 5 dB in comparison with that of ideal scheme at SER of 10^{-5} was observed. For a complexity comparison, the modified LS estimation had a lower complexity than the modified MMSE estimation. As a result, the adaptive protocol with the modified LS estimation provided the best performance among all other schemes for the cooperative communication systems.

***Abstract*— Ad hoc On-Demand Distance Vector (AODV), a widely deployed routing protocol in ad hoc networks, performs well in networks of high user density and low mobility. However, its performance drops for sparse networks with highly mobile users due to frequent broken links. This paper presents Mobility-Aware AODV (MA-AODV) routing protocol, which improves upon AODV by incorporating speed and direction of node movement in selecting neighbors. In particular, nodes with low relative mobility tend to form links with each other to increase the path lifetime. Compared to standard AODV, our simulation results show that MA-AODV only introduces minor overheads but reduces the amount of routing overheads caused by broken routes and route rediscovery. Furthermore, approximately 10% improvement in the packet delivery ratio is observed in MA-AODV under node mobility.**

I. INTRODUCTION

Mobile wireless networks have increasingly become more popular. Even in the absence of wired infrastructures such as access points, mobile devices or nodes can communicate by forming a Mobile Ad Hoc Network (MANET). In a MANET, packets sent by one node are forwarded by other nodes over the wireless medium until reaching the destination. Nodes in a MANET executes Ad hoc routing protocol in a distributed manner to determine the next-hop to forward packets.

One of the most well-known ad hoc routing protocols is Ad hoc On-Demand Distance Vector (AODV), which has been standardized by IETF [1]. A source node discovers a route to a given destination by broadcasting a Route REQuest (RREQ) packet with an originator's ID and a unique sequence number. Each immediate node along that path records the packet ID and the sequence number of the RREQ packet, creates a new routing entry whose destination field is the originator node with the next hop ID as the upstream neighboring node from which it receives the RREQ packet, as well as other related fields, and then rebroadcast. Upon receiving the RREQ packet, the destination responds with the Route REPly (RREP) packet back to the source by using the route recorded by the intermediate nodes in the forward path. If some intermediate node happens to have the entry for that destination, it returns an RREP packet itself. The immediate nodes along the reverse path is thus able to add the next node to forward the packet to this destination in their routing table. The route is said to be active if there are packets destined for this destination. A timer is used to purge inactive routing entry from the tables. Also, a node that detects a broken route will report to its upstream nodes back to the source so that the routing tables can be updated and the source initiates a new route discovery. To prevent routing loops, each routing entry utilizes per-node sequence numbers to ensure that the routes are loop-free. A node increments its sequence number whenever there is a change in its local connectivity information or requesting a new RREQ.

Broken routes, mostly caused by relative mobility, seriously decreases the end-to-end packet delivery ratio and increases the packet delay because of considerable amount of time and routing overheads to detect the broken routes and rediscover the new route to the destination. For example, in a multiple access link layer protocol such as IEEE 802.11b, a broken link leads to the absence of acknowledgment packets even if the node has successfully attempted the transmission. The retry attempts will be made for another 15 times before giving up, leading to significant amount of delay. Many techniques have been proposed to maintain good network performance under mobility. The problem is that AODV only maintains a single path for a given destination. Therefore, when the path is broken, data packets are simply dropped by nodes along the broken path.

In [2], [3], on-demand multi-path routing are proposed, whereby each neighboring node in a primary route also maintain its own backup route. When the node on a primary route detects a link failure, it transmits a route update message to its neighbors. The neighbor receiving this message then activates the backup route. [2] also introduces the term of goodness of preferential path probability to classify the goodness value. Recent work in [4] proposed the scheme that comes closest to ours work. The link breakage is reduced by enhancing the route discovery process of AODV using the concept of mobility aware agent. A mobile agent used at each node periodically broadcasts mobility information to its neighbors to collect node status and the selection of best neighbors for a given destination is done at each intermediate node. In this way, the agent attempts to establish a path between two nodes with minimum number of intermediate nodes. However, it does not clearly state the neighbor selection mechanism and how to elect the goodness value. In neighbor detection algorithm, [5] suggested using the Signal to Noise Ratio (SNR) value that is measured whenever a packet that contains an AODV message is received. A neighbor is classified good neighbor if the quality of the wireless physical channel is good enough to carry traffic. Note that this metric is representative of the distance, and may not correctly reflect how long two nodes

will remain neighbors.

In this paper, we propose the Mobility-Aware AODV (MA-AODV) routing protocol, which enhances AODV by selecting neighbors to forward packets based on relative mobility. Specifically, a node will select neighbors that would remain in its transmission range longest to extend the path lifetime. As shown in Fig. 1, nodes n and m on the right would remain neighbors longer than that in the left as they move in the same direction. A longer path lifetime not only reduces time and overheads spent on the new route discovery but also increases the packet delivery ratio as less packets are dropped due to broken links.

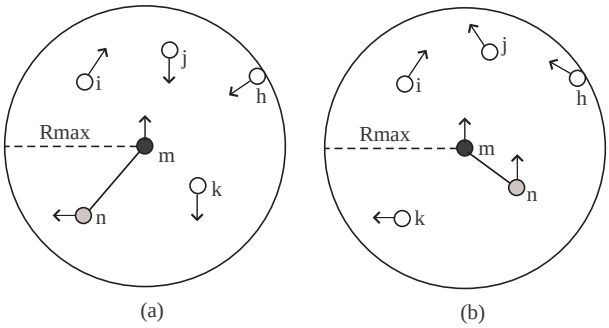

Fig. 1. Illustration of moving direction for each mobile node and its neighboring node: (a) Shorter session time. (b) Longer session time.

The rest of the paper is organized as follows. Section II describes the concept of relative mobility and how it is used to enhance the neighbor selection process in MA-AODV. In section III, we evaluate the performance of MA-AODV by means of simulation and compare its performance with standard AODV. Section IV concludes the paper.

II. Mobility-Aware AODV (MA-AODV)

In our work, we assume that the nodes use the same transmission range R and have a Global Positioning System (GPS) receiver to acquire its own coordinate, and this information is embedded into transmitted frames in the MAC level. Each node also uses the network interface that works in a promiscuous mode, which listens or eavesdrops every packets in its reception range, to mobility information of other nearby nodes. Fig. 2 illustrates walking routes of two mobile nodes moving independently and coordinate information is embedded to beacon packets broadcast periodically every one second by node M. The square and asterisk points indicate the sending and receiving of the beacons respectively by node M and N, while the dashed lines indicate the time period that M and N move out of one another coverage area.

Each node m maintains the position of all its neighbors n within its proximity for the last two updates. This information can easily be added to AODV routing update or HELLO messages that are already exchanged periodically. The relative velocity and other related parameters such as direction and the remaining session time can be established by using this

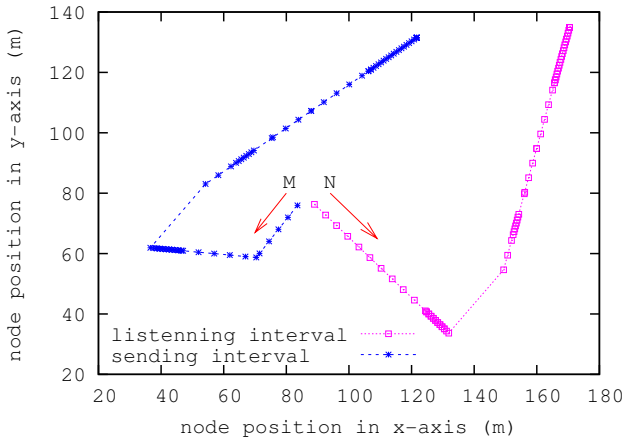

Fig. 2. Walking route of two nodes with periodic HELLO beacons.

information. Let

$$\underline{\boldsymbol{p}}_m(t) = [x_m(t)\ y_m(t)]^T \tag{1}$$

be the coordinate vector of node m at time t in the Euclidean space. Define $d_{m,n}(t)$ as the distance between node m and n at time t, which is given by

$$d_{m,n}(t) = \|\underline{\boldsymbol{p}}_m(t) - \underline{\boldsymbol{p}}_n(t)\| \tag{2}$$

where the operator $\|\cdot\|$ is an L_2 norm[1]. For every time interval τ, node m estimates the instantaneous velocity $v_{m,n}(t)$ that each of its neighbors n *moves outward* from the center of a circle where m is located along a *virtual* straight line toward the circumference.

$$v_{m,n}(t) = \frac{d_{m,n}(t) - d_{m,n}(t-\tau)}{\tau} \tag{3}$$

As shown in Fig. 3, the virtual straight line (the dashed line straightline) means that it is not the actual movement path. Rather, it is invented to model the distance that n moves out of the transmission coverage of m. The negative value of $v_{m,n}(t)$ indicates the inward movement while the positive value indicates the outward movement. Suppose the current

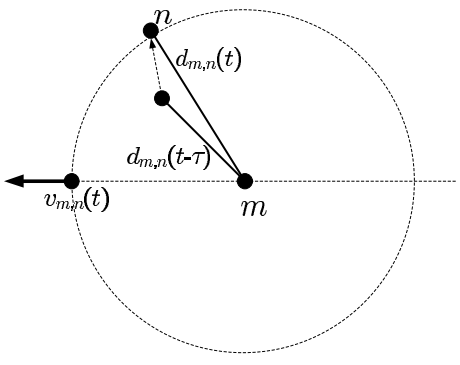

Fig. 3. Instantaneous velocity $v_{m,n}(t)$ of n moving out of m's transmission coverage.

[1]For a vector $\boldsymbol{a} = [a_1 a_2 \ldots a_n]$, $\|\boldsymbol{a}\| = \sqrt{\sum_{i=1}^{n} a_i^2}$

distance of n from m is $d_{m,n}(t)$. If n is moving away from m, it will take another $R - d_{m,n}(t)$ before n moves out of the transmission coverage of m. If n is moving closer from m, it will take another $d_{m,n}(t) + \frac{R}{2}$ before n moves out of the transmission coverage of m. Therefore, we can estimate the remaining session lifetime of n with respect to m at time t as

$$S_{m,n}(t) = \begin{cases} \frac{R - d_{m,n}(t)}{|v_{m,n}(t)|} & v_{m,n}(t) > 0 \\ \frac{R + d_{m,n}(t)}{|v_{m,n}(t)|} & v_{m,n}(t) < 0 \end{cases} \quad (4)$$

MA-AODV enhances the neighbor selection in the route discovery and route reply processes of standard AODV with the estimated session lifetime as described below. In standard AODV, the originator node initiates a RREQ. An intermediate node only responds the first RREQ, and then rebroadcasts. The RREQ finally reaches the destination or some intermediate node that has a route to the destination. In this phase every nodes can recognize and create a fresh routing entry containing next hop address used to reach the originator of RREQ. Also, a RREP is sent back to the originator to create another routing entry used to reach the destination of RREQ. Since the RREQ can traverse different paths to the destination, each intermediate node may receive multiple RREPs back from the destination. RREPs generated by the RREQ packet with the same sequence number are said be duplicates.

The process of updating the routing entry when receiving RREP gives the preference to various metrics in the following order: (i) sequence number, (ii) hop counts, (iii) expiration timer, and (iv) the estimated remaining session lifetime $S_{m,n}(t)$. A highest sequence number is given the highest priority as it represents the route reply for the newest RREQ. For RREPs with the same sequence number, they are duplicates and the one with lowest hop counts is selected. For duplicate RREPs with the same hop count, the one with highest expiration timer is selected as it represents the most recent route. The one with low expiration timer may imply that it is a cached route. For duplicate RREPs with the same hop count and expiration timer, it means they may be returned from the same intermediate node (or destination node) but traverse different reverse paths. This scenario is actually not uncommon. As shown in Fig. 4, node a receives multiple RREPs from different neighbors b and c, which in turn receive the RREPs from the same intermediate node when tracing back. In this case, both routes may have the same number of hop counts as well as the expiration timer. Therefore, the one with highest $S_{m,n}(t)$ is selected to ensure that the path will have a higher probability to remain longest.

III. Simulation Results

The simulation is implemented with OMNET++, a discrete-event simulation language based on C++[2]. The performance metrics are the packet delivery ratio and the routing overheads. The packet delivery ratio is the total number of received packets divided by the total number of packets sent, computed from all the nodes. The routing overhead is the number of packets generated by the routing protocol. The network consists of 50 nodes initially randomly placed in an area of 700 x 700 m^2. The MAC layer is IEEE 802.11b CSMA/CA with RTS/CTS and the common transmission range $R = 100$ m. The nodes move according to the random waypoint mobility model [6] with velocity selected from the range $(0, v_{\max})$. Five source nodes are selected to generate a constant bit rate traffic to a randomly selected destination at 10 packets/second (1460 bytes per packet) for 100 packets before terminating the session, and then selecting a new destination until the simulation terminates. Therefore, there are at most five concurrent sessions in the network to avoid the bandwidth saturation due to broadcast traffic. We implement the neighboring node detection module in the MAC layer using crossing layer concept introduced in [7]. Each data point is averaged from 15 runs, where each simulation run lasts 150 seconds.

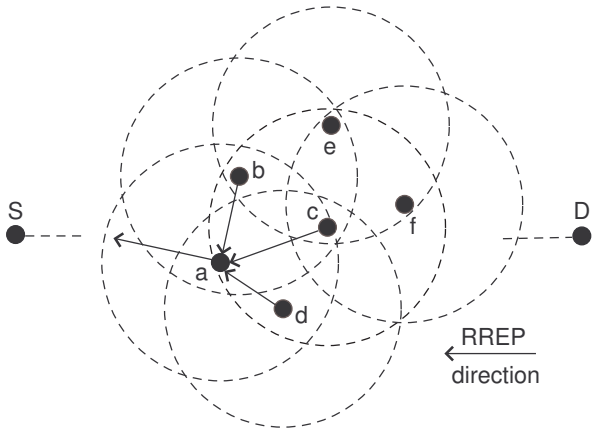

Fig. 4. Duplication of route reply from neighboring node known for the destination address.

Fig. 5 shows the packet delivery ratio as a function of the maximum speed $v_{\max}$. Both protocols have gradually decreasing delivery ratio as expected. However, MA-AODV performs slightly better in low mobility and the amount of improvement over standard AODV is approximately 10% as the mobility increases (from $v_{\max} > 6$ m/s). For instance, at $v_{\max}$ = 12 m/s, AODV delivers about 40% of total packets, while MA-AODV delivers about 53% due to its mobility awareness.

The amount of routing overhead packets shown in Fig. 6 indicates that MA-AODV generates less routing overheads because it maintain a longer path lifetime, and hence less overheads are generated due to the route update and rediscovery. The only additional overhead generated by MA-AODV is local update of node positions. While AODV does not have this update, it generates more routing overhead in RREQ flooding to discover a new route as a result of broken paths, which is more clearly observed when the velocity increases.

When increasing the network load by adding more sessions to the network, the packet delivery ratio drops for both AODV

[2]www.omnetpp.org

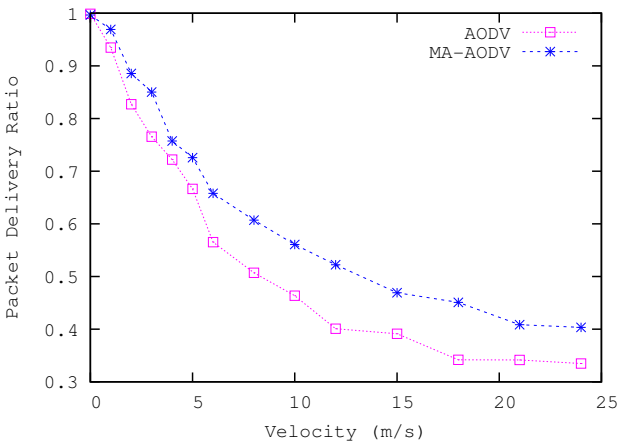

Fig. 5. Comparison of packet delivery ratio in AODV and MA-AODV as a function of the maximum velocity.

and MA-AODV as shown in Fig. 7.

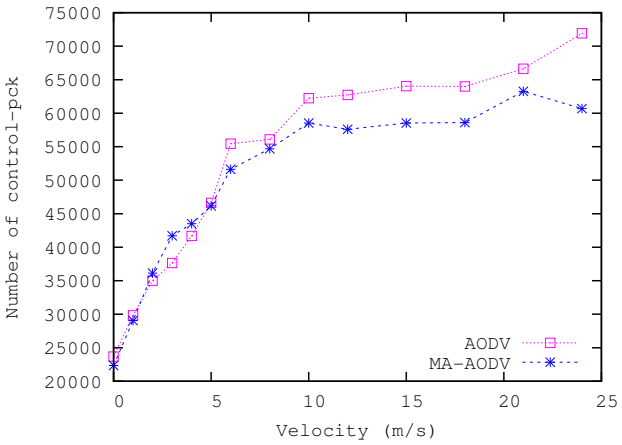

Fig. 6. Number of control packet vs. velocity.

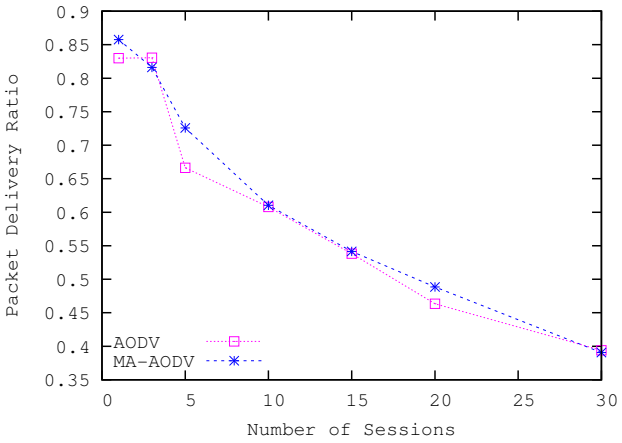

Fig. 7. Packet Delivery Ratio vs. Number of sessions ($v_{\max}$ = 5 m/s)

IV. Conclusion

In ad hoc networks, node mobility caused broken routes and leads to the route update and route rediscovery processes that waste time and network resources. Therefore, it is desirable to use the path that remains as long as possible. This paper proposes a MA-AODV ad hoc routing protocol, which enhances the neighbor selection process in standard AODV by using the estimated session lifetime. Each node estimates how long its neighbors will remain in its coverage area, or the remaining session lifetime, based on the history of coordinates broadcast by the neighbors. Compared to standard AODV, our simulation results show that MA-AODV reduced the amount of routing overheads caused by broken routes and route rediscovery. Therefore, packets are delivered with less end-to-end delay and more network resources are left to deliver packets. It has been shown that MA-AODV improves the packet delivery ratio approximately 10% over AODV.

***Abstract* - The growth of real-time multimedia applications in mobile ad hoc networks (MANETs) will be increasingly popular in the near future. To support such kind of applications, Quality of Service (QoS) features are desired. However, the mobile nature, limited resources, and dynamic topology of MANETs make it complicates to provide QoS guarantee in such network. In this paper, we propose a routing scheme for multimedia service based on multiple QoS constraint called QoS-Based Dynamic Source Routing (QDSR). It applies the source routing mechanism defined by the Dynamic Source Routing (DSR) to reduce routing overheads and improve throughput. QDSR gathers information about end-to-end delay, available bandwidth and signal strength during route discovery and uses the information in route decision process. We evaluate the performance of our proposed scheme by means of simulation. The result shows that QDSR provides the higher throughput and lower packet loss rate than those of DSR.**

***Keywords*: QoS routing, mobile ad hoc networks, Dynamic Source Routing.**

I. INTRODUCTION

A Mobile Ad Hoc Network (MANET) consists of wireless mobile nodes with no predetermined topology or central control. The nodes intercommunicate through single-hop or multi-hop paths in a peer-to-peer fashion and operate both as hosts as well as routers. Such network can be used in the situation where either there is no any wireless communication infrastructure present or such infrastructure cannot be used such as in battlefields, emergency search-and-rescue operations, and disaster environments [1]. Collaborative computing and communication in smaller areas (educational buildings, conferences, etc.) also can be set up using MANETs.

Since MANET is characterized by its fast changing topology, extensive research efforts have been devoted to the design of routing protocols for MANETs [1, 4, 5]. However, the most existing work is based on non-QoS requirement for example the source node attempts to transmit data to the destination node without any delay or bandwidth guarantee. As the real-time applications such as multimedia stream, live voice and video conference grow rapidly and sensitive with delay and bandwidth, QoS features become more important. However, the mobile nature, limited resource, and dynamic topology of MANETs make it complicates to provide QoS guarantee in such network.

There are many researches on QoS support in MANETs include QoS models [6], Layered QoS [2], QoS Medium Access Control (MAC) [7], and QoS routing [3, 8] which only consider with a single QoS constraint and sometimes it is not suitable to the highly unpredictable ad hoc environment. In order to guarantee the real-time and multimedia applications with QoS requirement, we propose a QoS-Based Dynamic Source Routing (QDSR) protocol. The protocol finds the route that meets the multiple QoS constraints and has a better chance for surviving over a period of time from node movement. The multiple QoS constraints considered here are delay, bandwidth and signal strength. The rest of the paper is organized as follows. In Section II, we introduce all related works. The proposed scheme QDSR is presented in Section III. Section IV presents our simulation and results. Finally, conclusion and future work are given in Section V.

II. RELATED WORK

A. MANETs Routing Protocols

Routing protocols in ad hoc networks can be classified into three groups [1]: *Proactive* (*Table Driven*), *Reactive* (*On-Demand*) and *Hybrid* as shown in Fig. 1.

A.1 Proactive (Table Driven) routing protocols

Proactive routing protocols come as a natural extension of protocols for the wired network. In these routing protocols, each node has a number of tables to maintain routing information to every other node in the network and these tables are updated periodically. Examples of proactive routing protocols are DSDV, WRP, CGSR [1] and so on. Since using periodic update, these protocols allow some significantly overheads and consume bandwidth in the network.

A.2 Reactive (On-Demand) routing protocols

Unlike proactive routing protocols, reactive routing protocols neither maintain nor periodically update their route tables. Several reactive routing protocols have been proposed such as DSR, AODV, TORA [1, 5] and so on. These routing protocols were designed to overcome the overheads occurred in proactive protocols.

DSR is one of the more commonly accepted routing protocols [5]. In DSR, when a node wishes to send data packets and does not have any routing information, it initiates a route discovery by flooding all of its neighbors with route request (RREQ) packets. Each neighbor broadcasts this

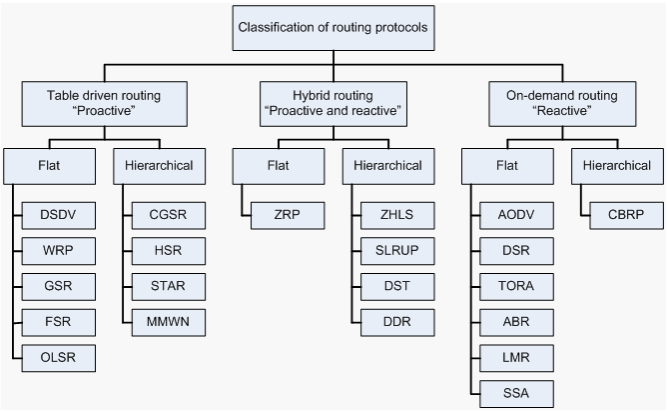

Figure 1. Classification of routing protocols

RREQ, adding its own address in the header of packet. When the RREQ is received by the destination or by a node that have a route to destination, a route reply (RREP) is generated and sent back to the sender along with the addresses accumulated in the RREQ header. Route maintenance is invoked when the source node detects the broken link and then it can choose any other route to the destination node or invokes the route discovery again to find the new route to destination.

A.3 Hybrid routing protocols

Hybrid routing protocols combine proactive and reactive routing protocols. These protocols are designed to increase scalability when the wireless networks become larger. All nodes in the network are separated into groups. Each group is called a cluster. All clusters form a hierarchical infrastructure. In these routing protocols, the proactive maintains routes in a cluster and reactive maintains routes between clusters. Several hybrid routing protocols have been proposed such as ZRP, ZHLS, DDR [1] and so on.

B. QoS Routing

QoS routing is the critical issue in MANETs due to mobility, mobile nature, and resource limitation. Some technical challenges are described in terms of designing optimal routes, providing reliable transmission, robustness, efficiency in resource utilization, adaptability, and unlimited mobility.

Normally, QoS routing protocols can be classified into two main groups. The first group concerns with some traditional protocols extended with QoS features. Their goal is to eliminate among the selected routes that do not meet the given criteria. The second group takes into account QoS aspect within the routing algorithm. Two types of constraints exist such as application specific [8, 10] (e.g. bandwidth or delay) and network specific features (e.g. congestion, energy constraint and link stability) [9, 11]. We can conclude that most of QoS routing protocols merely focus only on one application's QoS requirement based on a single QoS constraint which is not usually suitable to the highly unpredictable and dynamic ad hoc environment.

III. QoS-Based Dynamic Source Routing Protocol

In MANETs, the data service can be classified into two groups. The first group is the non real-time data service which bandwidth is not so sensitive and allows the delay during transmission. Examples of this service are file transfer, web documents and other traditional datagram applications. The second group is the real-time data service which bandwidth and delay are very sensitive such as on-demand multimedia stream, video and audio conference, etc. This kind of traffic needs QoS guarantee on the route. The proposed scheme constitutes an extension of DSR routing protocol, in which QoS features are embedded in the selection and maintenance of the routes.

A. QDSR procedures

QDSR relies on three procedures: route discovery, route reservation and route maintenance.

1. Route discovery

QDSR adds a QoS header to an ordinary route request (RREQ) packet and has the following fields: <*packet_type*, *source_addr*, *dest_addr*, *seq_num#*, *route_list, link_info* (*delay*, *bandwidth*, *signal*), *slot_array_list*, *traffic_type*, *bw_slot_req*, *qos_function*, *TTL*, *data*>. The following QoS metrics are used in our proposed scheme to provide the network layer with QoS requirement that are used during route discovery:

- **Delay**: The end-to-end delay from a source to a destination that the application can tolerate.
- **Bandwidth**: The lowest bandwidth that the application can tolerate on the route.
- **Signal Strength**: More stable route through dynamic network topology that has probability of surviving longer.

In this paper, we consider the combination of delay, bandwidth, and signal strength as the QoS function for selecting the appropriate route from source to destination.

a) Source node algorithm

When a source node wishes to send the real-time data packets, it first checks its resource availability such as free slots for bandwidth. If there is no resource available, the route discovery is canceled and the upper layer is informed. If the source node has sufficient resource, it will check the route in the route cache whether there is a route to the destination that satisfies the traffic requirement. If no valid route is stored in the route cache, the source node will place the information in RREQ header, initializes the QoS function and broadcasts the RREQ packet to its neighbors.

b) Intermediate node algorithm

This algorithm is executed by intermediate nodes on receiving a RREQ packet. From Fig. 2, we can explain the process of intermediate nodes as the following steps:

1. If the pair <*dest_addr*, *seq_num#*> for the RREQ is seen recently, check whether Time to Live (TTL) is zero or not, if TTL counts down to zero, we drop the RREQ and do not

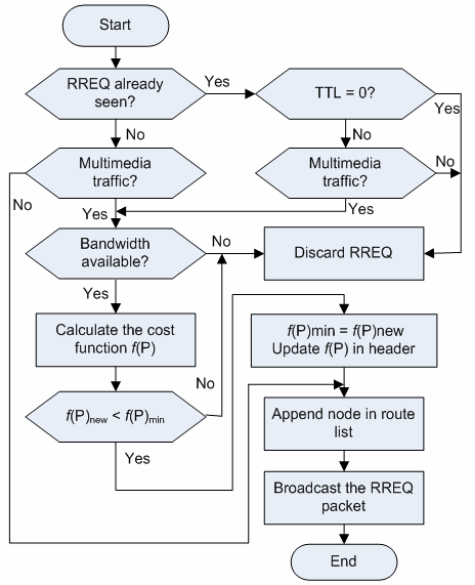

Figure 2. Intermediate node algorithm

process it further. TTL can limit the length of delivery path and control the flooding traffic.

2. Check whether the route request is searching for the path of multimedia traffic or common data traffic. If the traffic is multimedia traffic, the intermediate node calculates the available bandwidth from the source to this node using path bandwidth calculation and records the state of the data slots to the *slot_array_list*. If the result does not satisfy the QoS requirement, we drop the RREQ.
3. Compute the QoS function including the link delay, available bandwidth and received signal strength. The QoS function of path P is given by a heuristic formula (1):

$$f(P) = 1/\left((d - D(P))^{\alpha} + BW(P)^{\beta} + \left(S(P)/Rt\right)^{\gamma}\right) \qquad (1)$$

where $D(P)$ is the delay at given path, d is the maximum delay that application can tolerate, $BW(P)$ is the available path bandwidth, $S(P)$ is the minimum signal strength along the path, and Rt is the received signal threshold. α, β and γ are fixed parameters used to show relative importance about delay, bandwidth and signal strength in QoS routing.

4. Decrement TTL by one and append the address of this node to the *route_list* to track the route which the packet has traversed.
5. Selectively re-broadcast RREQ packet based on the QoS function. In order to reduce the broadcast storm and routing overhead, an intermediate node can re-broadcast a second RREQ packet only if it has lower QoS function than the first RREQ packet, otherwise the RREQ will be discarded.

c) Destination node algorithm

When the first RREQ packet with QoS enabled reaches the destination, the node starts the timer interval and during that time the node examines the QoS function of every arrived RREQ packet. When the timer interval expired, the destination node selects the RREQ packet that has the lowest QoS function and sends the route reply (RREP) packet carrying this route to the source node. When another RREQ packet with the same sequence number arrives after the threshold time interval, it will not be considered and do not process it further. Fig. 3 shows the process of destination node when receive RREQ packets.

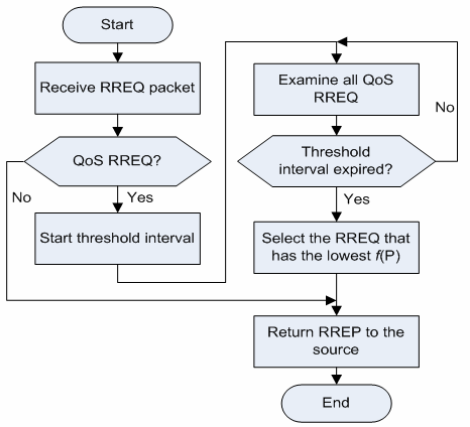

Figure 3. Destination node and route decision algorithm

2. Resource reservation procedure

On receiving the RREQ packet, the destination node reserves resource using a TDMA-based bandwidth reservation model. As a RREQ packet travels from the source to the destination, it automatically sets up the reverse path from the destination back to the source. From the RREQ packet, we can obtain the state of data slots and according to the information recorded within the RREQ packet. The destination can set up a QoS route and reserves resources (slots) hop-by-hop backward to the source. If the reservation operation fails or the resource are not available, a route error (RRER) packet is sent.

3. Route maintenance

If the destination node does not receive the data packet in reserved time slot, it considers that the link is broken and uses its dedicated control time slot to broadcast a route error (RERR) packet with finite TTL. Any node in the QoS route will forward the RERR packet to the source. On receiving the RERR packet, the source can re-establish a new RREQ with QoS enabled.

IV. Simulation and Result

Network Simulator (NS-2) is used to analyze the performance of QDSR. The performance of our proposed scheme is then compared to DSR. Only the route discovery procedure has been implemented and the maintenance procedure is the one implemented in DSR.

A. *Simulation model and parameters*

The simulations were run using an ad hoc network model composed of 8 nodes that moved randomly at uniform speed over a rectangular area 800 x 800m flat space. The simulation parameters and constant values for $f(P)$ in Eq.(1) are shown in Table I and II, respectively.

TABLE I. SIMULATION MODEL

Parameter	Value
Simulation area	800 x 800m
Number of nodes	8 nodes
Max speed	0 - 10 m/s
Node movement	Random
Transmission range	250 m
Source / Packet size	CBR / 512 bytes
Sending rate	20 packets/sec

TABLE II. CONSTANT VALUES

Constant	Value
α	0.3
β	0.3
γ	0.4
Max delay (d)	1 sec
Rt	3.65×10^{-10}

B. *Simulation results*

The result of simulation is shown in Fig. 4. We notice that QDSR improves the average throughput in comparison to DSR. When the mobility is increased, the performance of DSR will be significantly degraded. Adding more QoS criteria in the selection of intermediate nodes along the path leads to a more reliable data transmission which improves the throughput.

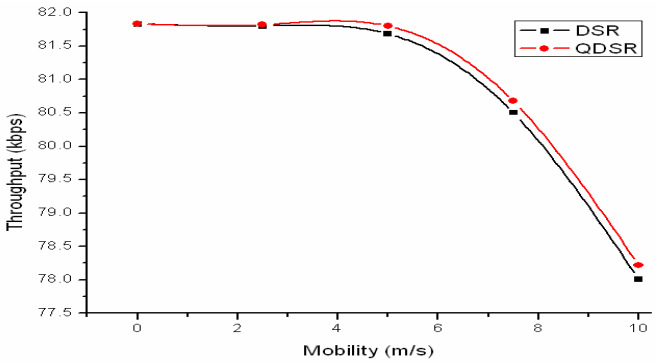

Figure 4. Average throughput versus mobility

In Fig. 5, we show the packet loss rate versus mobility. It also shows that the packet loss rate is proportional to the node's mobility. When the network becomes congested or the route is broken frequently due the mobility, many packets will be discarded or lost. The lower packet loss rate implies the more stable route. Since our proposed scheme involves the multiple QoS constraints and selects the most feasible and stable route, the probability of broken route can be decreased and that leads the lower packet loss rate than those on DSR.

V. CONCLUSION AND FUTURE WORK

We propose a new approach for QoS-aware routing to support multimedia applications in mobile ad hoc networks.

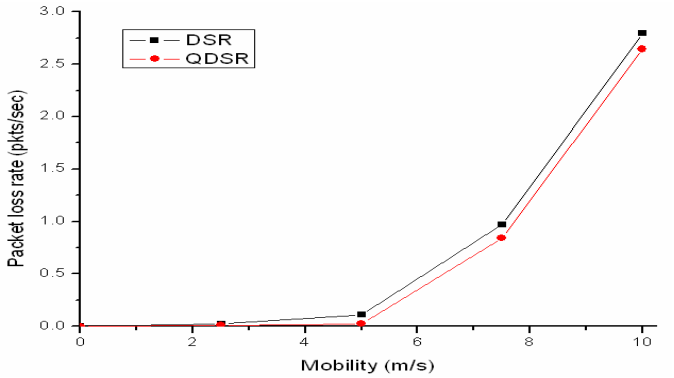

Figure 5. Packet loss rate versus mobility

Our proposed scheme, QDSR, considers with multiple QoS constraints such as delay, bandwidth, and signal strength to find the most feasible route from the source node to the destination node. It also selects the most stable links which leads to longer-lived routes and reduces route maintenance. We can conclude that our proposed scheme provides the improvement in terms of throughput and lower packets lost for real-time traffic and multimedia services in small networks.

Our future works will consequently consist in adding more functionalities such as improving the maintenance procedure and analyzing the effect of QoS function parameters on the performance of our proposed scheme.

cprommak@sut.ac.th, M4740452@sut.ac.th

***Abstract*-This paper presents a novel frequency channel assignment algorithm for Wireless Local Area Networks (WLANs). The proposed algorithm accounts the physical signal quality (considering SIR level in the service area) and the system throughput (considering the medium access control protocol, CSMA/CA). A multi-objective integer linear programming problem is defined. The proposed objective function separates the physical signal quality and the system throughput contributions in order to differently change the weights of the two characteristics of WLANs. Numerical results are presented and the jointed impact of signal quality and the system throughput are evaluated.**

I. INTRODUCTION

Frequency channel assignment is one of complicated tasks in the Wireless Local Area Networks (WLANs) design due to not only the limited unlicensed frequency spectrum in which the networks can operate but also the unique Medium Access Control (MAC) functionalities specified by the Institute for Electrical and Electronic Engineers (IEEE) 802.11 working group [1].

The IEEE 802.11b and 802.11g operate at the 2.4 GHz band while the IEEE 802.11a operates at the 5 GHz band. In North America, 83.5 MHz bandwidth is available in the 2.4 – 2.4835 GHz band while 300 MHz bandwidth is allocated in the 5.15 – 5.35 MHz (lower-band) and 5.725 – 5.825 MHz (upper-band). The 802.11 standard divides the 2.4 GHz band into eleven channels with center frequencies located 5 MHz apart as shown in Figure 1. Each channel has a frequency bandwidth of 22 MHz. Among these eleven channels are three channels whose bandwidths do not overlap each other. Those channels are 1, 6 and 11, as there is a frequency space of 3 MHz between channels 1 and 6 as well as between channels 6 and 11. These three channels are called the non-overlapping channels, and they can be assigned to adjacent APs without interfering with each other. The remaining channels overlap with one of the three non-overlapping channels and are called the overlapping channels.

Since a limited number of channels exist in the available frequency spectrum for an 802.11 WLAN, a multi-cell network deployment requires that some channels are reused. Reuse of frequency channels in neighboring cells can cause interferences in the service area. Thus, frequency channels of APs must be carefully assigned in the multi-cell WLANs.

The issues on quality of signal in the target service areas and the concerns about system throughput are two important metrics to be accounted in the frequency channel assignment process. However, in the majority of the published papers, the attention is focused on either one of the two aspects. Traditionally, the frequency channel assignment used in the cellular network design is based on the use of channel-separation matrix [2, 3] and the graph coloring approaches [4]. Recent study in [5] shows that the frequency channel assignment for WLANs using the signal quality based approach outperform those using the traditional channel-separation based approach and yield WLAN systems with higher signal quality in the service area. However [5] does not consider throughput of the WLAN system. Recent work [6] considers the medium access control (MAC) protocol in the frequency channel assignment procedures but only focuses on maximizing system throughput and does not consider coverage of signal in the service area.

In this paper we propose a hybrid technique that allows to optimize both criteria (signal quality and system throughput). We present a multi-objective integer programming model for the frequency channel assignment problem (FCAP) for WLANs. The proposed model takes into account the interference level and the WLANs' MAC protocol to reflect the target criteria.

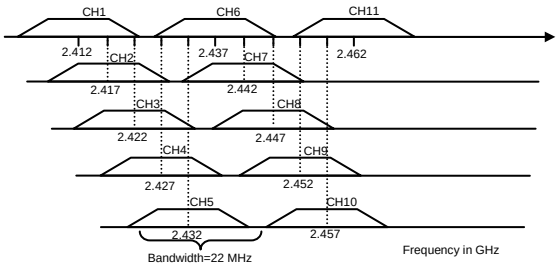

Figure 1 Frequency spectrum allocation for IEEE 802.11b and 802.11g

The rest of the paper is organized as follows. The next section describes the problem definition of the FCAP for WLANs and gives the mathematical formulation of the FCAP model. Section III gives numerical results and discussion. Section IV provides conclusions.

II. Problem Definition and Formulation

In WLANs context, the Frequency Channel Assignment Problem (FCAP) involves assigning frequency channels from a set of available channels to the access points (APs) in WLANs. In this paper we jointly determine the locations to install APs while considering fixed level of AP transmitting power (which is a given value). The proposed FCAP model takes into account two important aspects of the WLAN operation, including the signal quality in the service area and the system throughput.

A. System Throughput Considerations

In WLANs, user terminals rely on a common (broadcast) transmission medium. Only one terminal can occupy the medium at a time. If multiple terminals simultaneously transmit, a collision may occur and the signal could be corrupted. The IEEE 802.11 standard specifies a Medium Access Control (MAC) protocol, called Carrier Send Multiple Access/ Collision Avoidance (CSMA/CA), to coordinate transmission of the user terminals. This coordination is achieved by means of control information. This information is carried explicitly by control messages traveling in the medium (i.e. ACK messages) and can be provided implicitly by the medium itself through the use of a carrier-sensing mechanism before each transmission to check if the channel is either active or idle.

Control messages and message retransmission due to collisions consumes medium bandwidth. They are overhead required by a MAC protocol that coordinates transmissions of user terminals. According to the throughput analysis of the CSMA/CA protocol, the AP throughput varies depending on the number of users connecting with the AP [7]. As the number of wireless users in the AP coverage area increases, the AP throughput decreases. An efficient frequency channel assignment technique accounting for the CSMA/CA protocol can help improve the AP throughput, resulting in higher system throughput.

Thus, the important objective function for the FCAP with the system throughput consideration is to maximize the system throughput which is a summation of throughput of all APs used in the network. This objective can be written as follows:

$$f_1\text{: } max \sum_{\forall j \in A} t_j \qquad (2)$$

We adopt a throughput estimation technique developed in [6] to compute AP throughput (t_j). Please refer to [6] for detail equation and parameters to compute t_j.

B. Signal Quality Considerations

In the proposed FCAP model, we consider signal quality in the network because the service availability of the network depends on availability of the radio signal and the level of interferences in the area. In particular, we adopt the signal-quality based approach presented in [5] which considers the signal to interference ratio (SIR) that is assessed at all STPs in the target service area. Thus, the important objective function for FCAP with the signal quality consideration is to maximize the signal coverage availability by maximizing the number of STPs whose SIR are greater than the specified threshold. This objective can be written as follows:

$$f_2\text{: } max \sum_{\forall g \in G} x_g \qquad (1)$$

C. Math Model

On the basis of the signal quality and the system throughput considerations, the problem of assigning the best frequency channels to APs in WLANs, accounting the interference level and the CSMA/CA functionalities, can be mathematically formulated as the hybrid model written below.

$$f_3\text{: } max \quad w_1 \sum_{\forall j \in A} t_j + w_2 \sum_{\forall g \in G} x_g \qquad (3)$$

The objective function f_3 is a popular approach used to deal with multi-objective optimization problems [8], transforming the problem f_1 and f_2 into a single objective function that maximizes a combination of the two problems by using factors w_1 and w_2 to weight the importance of each problem.

TABLE I
NOTATION USED

Notation	Definition
A	Set of access points (APs) in the network. $\|A\|$ is the total number of APs used in the network.
G	Set of Signal Test Points (STPs). It represents locations in the service area where the signal to interference ratio (SIR) level are assessed. $\|G\|$ is the total number of STPs in the service area.
s_g	SIR assessed at STP g, $g \in G$
s_t	SIR threshold
x_g	Binary variable equals 1 if $s_g > s_t$; 0 otherwise
t_j	Throughput of AP j, $j \in A$
f_j	Frequency channel of AP j, $j \in A$
w_1	Weight ascribed to the system throughput consideration
w_2	Weight ascribed to the signal quality consideration

III. Numerical Results and Discussion

To evaluate the performance of the proposed hybrid FCAP model (f_3), we conducted numerical experiments using the same test scenario as that used in [6] where the building floor is divided into grid granularity of 5 m., a uniform distribution of user terminals was considered and the 16 AP candidate locations were given. The Two-Ray-Ground model was used to predict the signal strength. We considered three non-overlapping frequency channels (1, 6, and 11) for the frequency assignment and used the SIR threshold of 10 dB. We used $w_1 = w_2 = 0.5$.

We compared frequency channel assignment solutions obtained by the three FCAP models, f_1 (the throughput based model), f_2 (the signal quality based model) and f_3 (the hybrid model), where the solutions were found by using the patching algorithm [6]. The resulting WLAN systems using the frequency channels obtained by each model were compared in term of the coverage area and the system throughput.

Figure 2 and 3 compare the system throughput and the coverage area of the WLAN system using frequency channels obtained by the model f_1, f_2 and f_3. We can see that the hybrid model, f_3, yields the WLAN system with high system throughput and good signal coverage. Figure 2 shows that f_1 results in the highest system throughput while f_2 results in the lowest system throughput. We can see that f_3 results in very high system throughput, much better than that of f_2 and only slightly less than that of f_1. Figure 3 shows that f_1 results in the lowest coverage area while f_2 and f_3 result in the highest coverage area.

We conducted another set of numerical experiments to study effects of number of users in the service area on the performance of the FCAP model. We considered three scenarios of the use density; low, medium and high. We used a uniform distribution of 0 to 2 users per grid in the low user density scenario, 2 to 4 users per grid in the medium user density scenario, and 4-6 users per grid in the high user density scenario.

From figure 4 and 5, we can observe that in all case of user density f_3 results in higher system throughput compared to that of f_2 and results in better signal coverage compared to that of f_1. Although f_1 yields WLAN system with higher system throughput but it results in much less signal coverage compared to that of f_3. For example, in case of high user density, coverage area of the WLAN system using f_1 is 50.8% less than that using f_3.

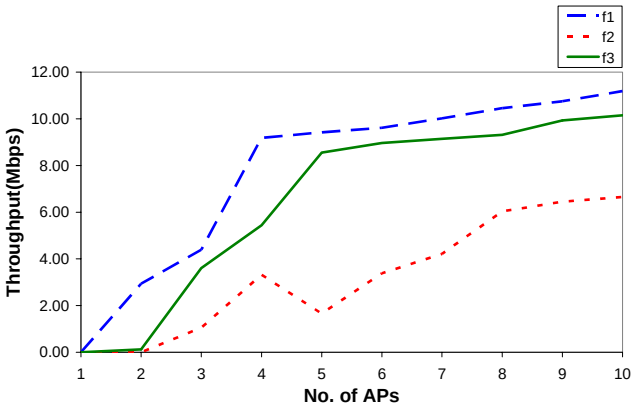

Figure 2. System throughput comparison as the number of APs increases

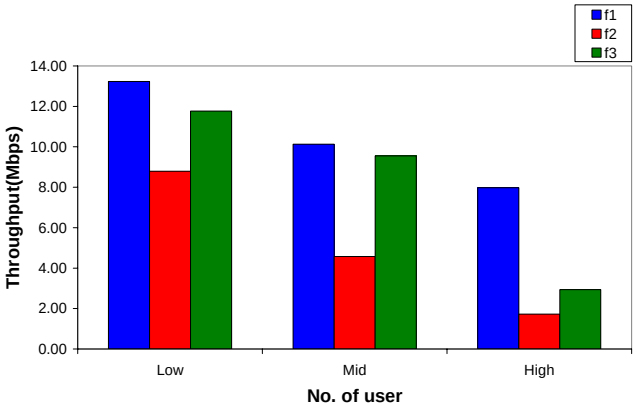

Figure 4. System throughput comparison as the number of users increases

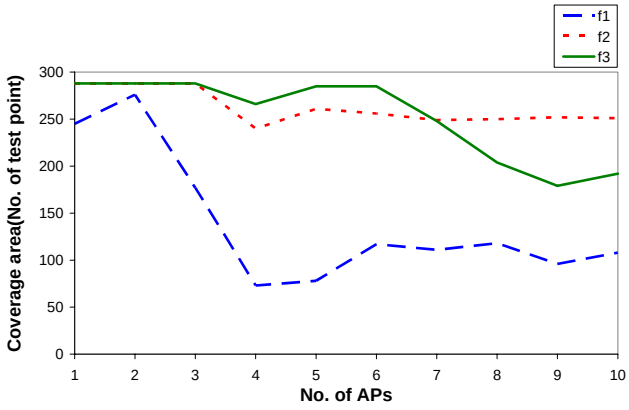

Figure 3. Coverage area comparison as the number of APs increases

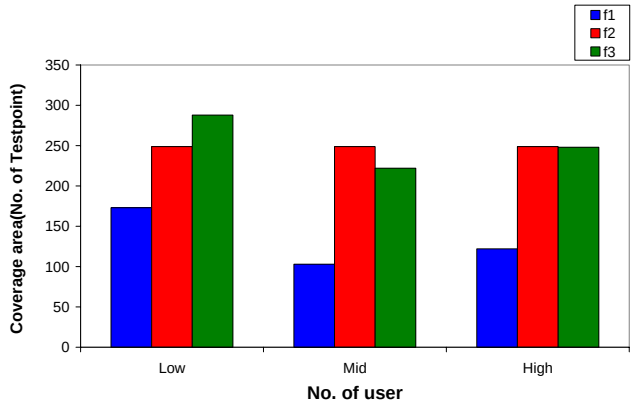

Figure 5. Coverage area comparison as the number of users increases

IV. Conclusion

A novel hybrid model that accounts the system throughput and the signal quality in the service area has been formulated as a multi-objective linear programming. The numerical results show that the hybrid model can enhance the WLAN system performance in term of system throughput and coverage area while the signal quality based model results in low system throughput and the throughput based model results in poor signal coverage.

***Abstract*- A compact two-layer dual-band bandpass filter using aperture-coupled microstrip stepped-impedance hairpin resonator is proposed and designed to operate at 2.4 and 5GHz band. The proposed dual-band filter is composed of four stepped-impedance hairpin resonator located on two stacked microstrip layers. To validate the design and analysis, a prototype of the dual-band bandpass filter was fabricated and measured. It is shown that the measured and simulated performances are in good agreement. The prototype of the dual-band bandpass filter achieved insertion losses of 2.29 and 2.978 dB, return losses of 20 and 15 dB at 2.4 and 5GHz band, respectively. As result, a significant reduction of approximately 50 % is achieved.**

I. INTRODUCTION

Microwave planar bandpass filters are mostly employed in wide applications of wireless communication systems in the present day [1]. Recently, in exploring advanced dual-band wireless systems, filters with dual-band operation for microstrip devices have become quite popular. Therefore, dual-band filters have been widely studied in several papers. This type of dual-band filter was initially reported in [2]-[8] by the combination of two individual filters with two specific single passbands. Extra impedance-matching networks must be used to design the input and output structure of the filter. Unfortunately, this solution suffers from high insertion loss and large overall size in its resultant filter block. Using the basic topology of a stopband filter in [3] and [4], uniform transmission line is interrupted with multiple shunt stubs of unequal lengths so as to enforce the emergence of dual passbands relying on multiple transmission zeros. Parallel-coupled microstrip dual-band filter without any external feeds is originally presented in [5] to realize the controllable dual-passband bandwidth at the two specified frequencies. On the other hand, an increasing interest has been recently moving to utilize the stepped-impedance resonator (SIR) for constructing the dual-band resonators by properly selecting the relevant impedance or strip width ratio [6]-[8].

As a consequence, this approach may cause some problematic issues, such as large size and extra loss in design. To resolve this problem, two–layer or multilayer filter designs become suitable approaches for a filter-size reduction. For instance, these two-layer filter structures have been presented in [9] and [10]. In approaches, open-loop resonators have been employed. In the same perspective, another two-layer design with one aperture for the mixed coupling has been investigated in [11]. From previous approaches, it can be noted that only open-loop resonators with one type of coupling have been considered.

This paper presents a four-pole chebyshev function dual-band bandpass with aperture-coupled microstrip resonators. By using two-layer technique, the dual-band filter has a compact size, which is much smaller than single layer. In addition, the cross-coupling between nonadjacent resonators creates transmission zeros that improve the selectivity.

In section II, theories and guidelines for calculating the geometric parameters of SIRs have been presented. The design procedures for the filter are given in section III. The simulation results are compared with the measured data. Finally, brief conclusions are draws in section IV.

II. CHARACTERISTICS OF STEPPED-IMPEDANCE RESONATOR

The basic structure of a half-wavelength microstrip stepped-impedance resonator (SIR) is shown in Figure 1. It consists of two lines of different characteristic impedance Z_1 and Z_2 and of electrical lengths θ_1 and θ_2 , respectively. To simplify the theory analysis, the basic structure of a half-wavelength SIR, show in Figure 1. Ignoring the effect of the step discontinuity, the fundamental resonance condition of a SIR can be derived by examining the input admittance Y_{in} of the composite transmission line from the open plane, and it can be written as [12].

$$Y_{in} = jY_2 \frac{Y_2 \tan\theta_1 \tan\theta_2 - Y_1}{Y_2 \tan\theta_1 + Y_1 \tan\theta_2} \tag{1}$$

The resonance condition given by $Y_{in} = 0$ can be described as follows:

$$\tan\theta_1 \tan\theta_2 = R \tag{2}$$

where the impedance ratio R is defined by

$$R = \frac{Z_2}{Z_1} = \frac{Y_1}{Y_2} \tag{3}$$

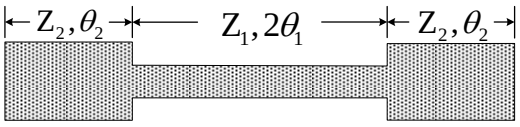

Figure 1. Basic structure of the stepped-impedance resonator (SIR)

The relationship between the total electric length θ_T and the resonator and electric length θ_1 is given by

$$\theta_T = 2(\theta_1 + \theta_2) \quad (4)$$

$$\theta_T = 2\left(\theta_1 + \tan^{-1}\left(\frac{R}{\tan\theta_1}\right)\right), \quad R \neq 1 \quad (5)$$

$$\theta_T = \pi, \quad R=1 \quad (6)$$

From Eq. (4), it can be shown that the resonator length reaches a minimum value for 0< R < 1 and a maximum value when R>1, which means that we should choose a very small value of R in order to obtain the smallest filter size. It may be shown that the first spurious resonance frequency is given by [12]

$$\frac{f_{s1}}{f_0} = \frac{\pi}{2\tan^{-1}\sqrt{R}} \quad (7)$$

From Eq. (7), it is clear that the spurious response can be controlled by the characteristic impedance ratio R. In this design, we set f_0 and f_{s1} to be 2.442and 5.250 GHz, respectively.

III. Filter Design and Measured Results

A. Coupling Coefficients

In order to design filters with required specifications, such as bandwidth, it is necessary to evaluate the coupling coefficients *k* between two adjacent resonators. In this way, the dependence of the electric coupling and magnetic coupling can be expressed as a function of the distance. However, the mixed coupling coefficient depends on the dimensions and the location of the apertures. It has been known that the coupling coefficient of two coupled resonators can be extracted from resonant-mode splitting [9].

Figure 2 shows the simulated resonant frequency responses of coupled resonator structures. Two split resonant-mode frequencies are easily identified by the two resonant peaks. To simulate the frequency responses of these basic coupling coefficients, full-wave simulator (IE3D) was used. The coupling coefficient can be graphically estimated from these two resonant frequencies, and they are extracted using the following relation

$$k_{ij} = \pm\frac{f_b^{\,2} - f_a^{\,2}}{f_b^{\,2} + f_a^{\,2}} \quad (8)$$

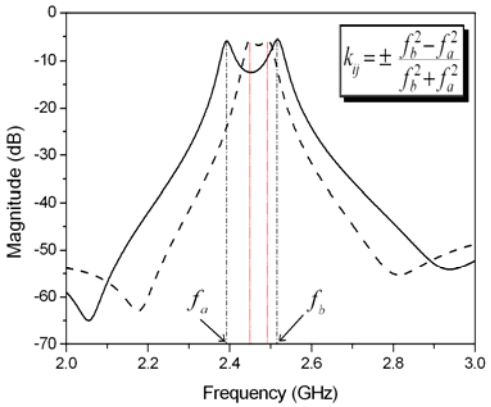

Figure 2. Resonant responses of coupled resonator structures.

where f_a and f_b are the lower and higher split resonant frequencies of a pair of couple resonators.

Figure 3 shows the three possible coupling coefficient curves as a function of distance d for the electric and magnetic couplings or aperture dimensions dx, dy for mixed coupling, respectively. From these results, it can be seen that the mixed coupling increases as aperture sizes are increased.

B. U-Shaped Defected Ground Structure (DGS)

A compact duable equilateral U-Shaped DGS unit is proposed in [13]. The dimension structure of U-Shaped DGS shown in Figure 4 with proper design, the stopband performances of the structure consists of two slot defected areas. Therefore, the dimension must be optimized to get the proper high performance stopband response.

C. Measured results

Based on the proposed design, dual-band bandpass filter prototype using two layer substrates was fabricated. The filter prototype was built with GML 1000 substrates with a relative dielectric constant of 3.2 a loss tangent of 0.004 and thickness of 0.762 mm by using a standard printed circuit board (PCB) process. Figure 5 shows cross-sectional view of two-layer dual-band bandpass filter. The optimized filter layout parameters have been obtained in the following d_{14}= 0.544mm, d_{12}= 0.477mm, d_{23}= 0.85mm, d_x= 4.52mm and d_y= 3.2695mm, W_a = 0.7mm, W_b = 0.3mm, L_a = 3.76mm and L_b = 3.0mm, respectively.

Figure 6 shows a prototype, where only the two resonators on the top layer are visible. To examine the filter performances, experimental measurements were carried out using an Agilent 8719ES network analyzer. Figure 7 shows the simulated and experimental results of S_{11} and S_{21}. It can be observed that the simulated and measured results display a good agreement. The measured return losses in both 2.4GHz and 5GHz bands are higher than 18 dB while the measured insertion losses are 2.29 dB and 2.978 dB, respectively.

Designed defected ground structure shows that the stopband performances of the proposed filter have drastically improved, that the measured harmonic suppression of better than -10 dB up to about 13GHz is shown in Figure 10.

IV. CONCLUTION

In this paper, a new compact dual-band bandpass filter using aperture-coupled microstrip SIR-hairpin resonator on a two-layer structure has been proposed and investigated. In the proposed design, the couplings between the filter resonators have been achieved through apertures etched in the common ground placed between the two layers. Base on this architecture, we can easily achieve a significant size reduction of 50% compared with conventional single-layer filters. Furthermore, the aperture coupled technique used in the design is efficient, simple and easy to be implemented. In addition, a good agreement has been achieved between experimental and simulated results. With these features, the proposed dual-band bandpass filter is suitable for compact microwave systems.

***Abstract* -This paper presents the treatment of pulmonary carcinoma using microwave coagulation therapy with open-tip and multi-slot coaxial antennas. Because lung is a common site for cancer and usually has substantial functional reserve, MW ablation of lung cancers is an attractive option for minimally invasive treatment. We performed finite element analysis simulation of microwave ablation and analyzed heating characteristics of open-tip and multi-slot coaxial antennas. We also performed *in vitro* experiments and analyzed heating characteristics in swine-lung tissue during application of microwave energy through open-tip and coaxial-slot antennas. The validity of the analysis was confirmed by comparison of the results from the simulation and *in vitro* experiments.**

Keyword: MCT, lung Cancer, open-tip, multi-slot

I. INTRODUCTION

Microwave coagulation therapy (MCT) has been used extensively for the treatment of hepatocellular carcinoma [1], [2]. Microwave ablation technique is minimally invasive, thus it requires shorter recovery period compared to surgical resection. In the treatment, a thin microwave antenna is inserted into the tumor, and the microwave energy provided by the antenna heats up the tumor to produce the coagulated region covering cancer cells. The input power of the antenna is usually less than 50 W. The goal of microwave ablation is to elevate the temperature of unwanted tissue to above 50 °C where cancer cells are destroyed [3].

From our literature review, no previous studies have discussed the use of microwave ablation for treatment of lung cancer. However, previous studies using radio-frequency (RF) ablation for lung cancer have been reported [4]. Using microwave is potentially more effective than using RF due to air-filled anatomical structure of the lung. For RF ablation of lung carcinoma, the major problem is that the size of coagulated region is generally insufficient due to low RF energy deposited in lung tissue.

In this paper, we used finite element method (FEM) to determine electromagnetic fields and heating patterns of various antenna designs. Then we constructed the antennas with desirable characteristics and utilized them to perform *in vitro* experiments using swine lung tissue.

II. MATERIALS AND METHODS

(a) Open-tip and multi-slot coaxial antennas

Fig. 1 (a) and (b) show the configuration of the open-tip antenna (OTA) and multi-slot coaxial antenna (MSCA). Table 1 lists all related structural parameters of the antennas. Here, d_a is the diameter of the antenna; d_b is the thickness of the dielectric; d_c is the thickness of the conductor; d_g is the length from the tip to the center of the slot; and d_f is the width of the slot. We used a thin semi-rigid coaxial with a diameter of 3.6 mm. Table 2 provides values for the relative permittivities of the materials used in the antennas.

(b) Finite element studies of coupled thermal-electromagnetic analyses

Since our goal is to compare the characteristics of different antenna designs in terms of energy and heating distribution, we performed all analyses using the bio-heat and Maxwell's equations. Finite element analysis was utilized to obtain approximate numerical results of the complex coupled thermal-electromagnetic problems by dividing the domain of interest into many small areas with simple geometry. We describe the bio-heat equation and calculation of the specific absorption ratio (SAR) in this section.

Bio-heat equation

We can calculate the temperature distribution inside the biological tissue by solving the bio-heat transfer equation

$$\rho c \frac{\partial T}{\partial t} = \nabla \bullet (k \bullet \nabla T) + \rho_b \rho_b c_b \omega_b (T_b - T_b) + Q_{met} + Q_{ext} \qquad (1)$$

where T is the temperature (˚C), t is the time (s), ρ is the density (kg/m^3), c is the specific heat (J/ kg· K), k is the thermal conductivity (W/m·K), ρ_b is the density of the blood (kg/m^3), c_b is the specific heat of the blood (J/kg·K), w_b is the blood perfusion rate (m^3/kg·s), T_b is the temperature of the blood (˚C).

The first, second, and third terms on the right hand side of (1) denote thermal conduction, heat dissipation by the blood flow, and heat generation by the electric field (Q_{ext}), respectively. Q_{met} is the amount of heat generated by metabolic process and is comparatively much smaller than the previous terms. Thus Q_{met} is considered negligible in this study.

Calculation of SAR

We can calculate SAR using equation (2):

$$SAR = \frac{\sigma}{\rho}\left|E^2\right| \qquad [W/kg] \qquad (2)$$

where σ is the electrical conductivity [S/m]

ρ is density $[kg/m^3]$ and

E is the electric field intensity (rms) [V/m]

Software simulation

In this study we performed finite element analyses using COMSOL version 3.2b. We ran all simulations on a PC with Intel Pentium M, 1.5 GB of RAM, and 50 GB of Hard disk space. There were three types of MW antennas used—OTA, 1-slot MSCA, and 2-slot MSCA. For each case, we set the input power to 80 W, for a duration of 30 s.

In vitro Studies

We constructed the OTA, 1-slot MSCA, and 2-slot MSCA using the semi-rigid coaxial cables. We tested each antenna in *in vitro* experiments using swine lung tissue. The microwave power generator was built in house and was able to supply 0-100 W to the MW antenna. Swine lung tissue was placed in a saline bath and MW energy was delivered to each antenna. In addition, we measured SAR and temperature distribution along the shaft of each antenna using the Bird Site Analyzer (Electronic Corporation, Cleveland (Solon) Ohio, USA).

III. RESULTS

Fig. 2 illustrates SAR distributions along the axial surface of OTA, 1-slot MSCA, and 2-slot MSCA from finite element analyses. Table 3 lists VSWR for each antenna used. Table 3 lists Voltage Standing Wave Ratio (VSWR) measured with the Bird Site Analyzer in *in vitro* experiment. Graph 1 shows the distribution of SAR in lung tissue from the three antennas. Fig. 3 compares temperature distributions of the three antennas along their axes. Graph 2 shows corresponding temperature distributions and Fig. 4 displays temperature gradients within lung tissue for in vitro experiment.

Fig. 2 and graph 2 show the level of temperature distribution of the tree types of the antennas in pulmonary tissue. As shown in fig. 2 and graph 2, the 1 slot has the highest level of temperature. The 1 and 2 slots have the temperature distributions around the slots and the tips of the antennas. The open-tip has lower level of temperature than the 1 and 2 slots

Experiment Results

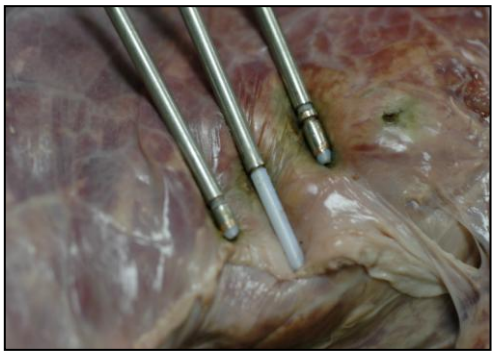

Figure 4. Lesions created in swine lung tissue using 1-slot MSCA, OTA, and 2-slot MSCA.

Fig. 4, in vitro experiment, shows that the analysis with the finite element method gave the simulation result similar to the in vitro experiment.

IV. Conclusions

This study presents 2 different antenna designs—OTA and MSCA—for use in lung cancer treatment. Due to high electrical resistivity in lung compared to other tissues, using microwave ablation can be potentially more effective than RF ablation. With OTA design, the location with optimal SAR occurs at regions adjacent to the outer conductor. For MSCA, optimal SAR is distributed close to the slots. From both FE analyses and in vitro experiments, 1-slot MSCA appeared to have a higher maximum temperature compared to that of OTA. When we increased the slot from 1 to 2, the maximum temperature in lung tissue decreased, however, the maximum temperature region was more widely distributed. The different results obtained from each antenna design can be applied to appropriate treatment criteria

***Abstract*-This paper presents the simulation of the parasitic capacitance cancellation technique of inductor using mutual capacitance. Its mutual capacitance can be emulated using two small capacitors, connected with circuit. The simulation using PSpice program to simulate mutual capacitance concept is presented. The objective of this paper is to analyze the high frequency inductor performance using PSpice simulation. Finally, the simulation results show that the performance of inductor is improved.**

I. INTRODUCTION

The EMI filter is typically composed of inductors and capacitors, which is considered only the inductors in this paper. Theoretically, the impedance of inductor is increased while the frequency increased. Therefore, the inductor's operation frequency range is limited because of the parasitic capacitance, which makes an inductor changing to a capacitor at high frequency. The parasitic capacitance is usually lumped together as an equivalent parallel capacitance (EPC), and the winding loss and core loss of the inductors are usually lumped together as an equivalent parallel resistance (ESR), paralleled to the inductance L [1]. Fig. 1 shows a simple model for inductor.

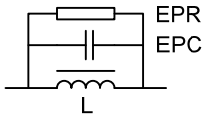

Figure 1. Equivalent circuit for a practical inductor.

The advantages of PSpice simulator, when comparing with practical experiment, can minimize the experiment time. Because there are too many equivalent and step in the practical experiment, if some mistakes take place, it must takes time to repair them. By simulation, it can be more convenient, rapid and high accuracy.

II. THE SIMULATION PROCEDURE USING PSPICE PROGRAM

The simulation of winding capacitance cancellation, by PSpice program, is simulated the measured results of network analyzer by its AC sweep mode with 150 kHz for initial frequency, 1000 Hz for step frequency, and 30 MHz for final frequency. The inputs of PSpice circuit are connected to AC source, 1 V, then, calculating the simulated results following Eqn. (1). The inputs and outputs of PSpice circuit are connected to resistor 50 ohm because the impedance of connectors of network analyzer is 50 ohm for matching impedance. The voltage probe is used to measure difference voltage across the resistor. Fig. 2 shows the circuit for measurement with four ports balances ENA RF [3], and Fig. 3 shows the simulated circuit using PSpice program.

$$\text{Inductor filtering performance} = 20\log\frac{V_{out}}{V_{in}}\ \text{dB} \qquad (1)$$

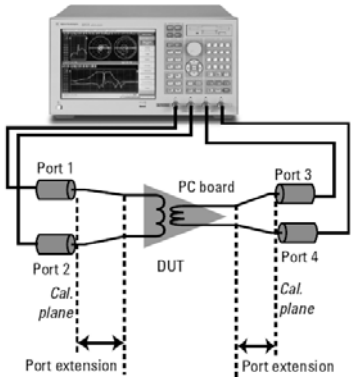

Figure 2. The method of network analyzer (Agilent E5070B/E5071B).

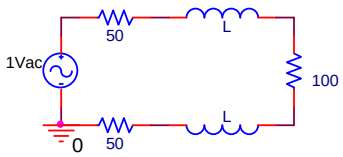

Figure 3. The simulation of PSpice program

The simulation of parasitic capacitance and resistance are emulated by capacitor and resistor of PSpice program, paralleled to the inductance L, as shown in Fig. 4. The parasitic capacitance and resistance are measured by impedance analyzer.

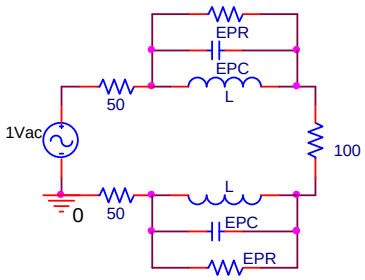

Figure 4. The parasitic capacitance is emulated by PSpice program.

III. Simulated Results

At frequencies higher than the self resonance frequencies of the inductors, the inductors perform like capacitors, and therefore, the filter with parasitic capacitance is worse more than the filter without parasitic capacitance as shown in Fig. 5.

Fig. 5 shows the simulation of parasitic capacitance, which effects to performance of the EMI filter. As shown in Fig. 5 (a), the inductors are connected with capacitances. As shown in Fig. 5(b), the inductors are connected without capacitances. The self-parasitic of two inductors, measured by impedance analyzer, are $L_1 = L_2 = 3.21$ mH, EPC_1=$EPC_2 = 30$ pF, and EPR_1=$EPR_2 = 15.7$ kΩ. The compared result is shown in Fig. 6, which is compared between simulated results of with and without parasitic capacitances as shown in Figs. 5 (a)-(b), respectively. The performance of inductor with parasitic capacitance has a resonance frequency around 500 kHz, which makes the inductor performance worse more than inductor without parasitic capacitance.

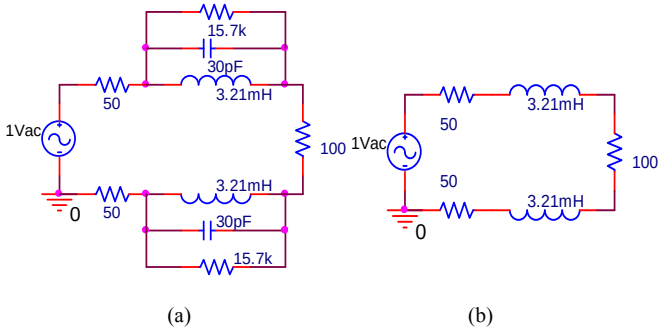

Figure 5. The simulation of inductor
(a) with parasitic capacitance (b) without parasitic capacitance.

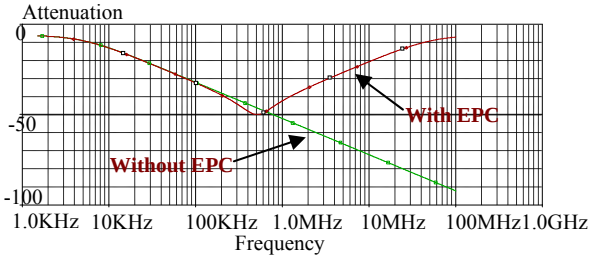

Figure 6. The simulation of inductor
(a) with parasitic capacitance
(b) without parasitic capacitance.

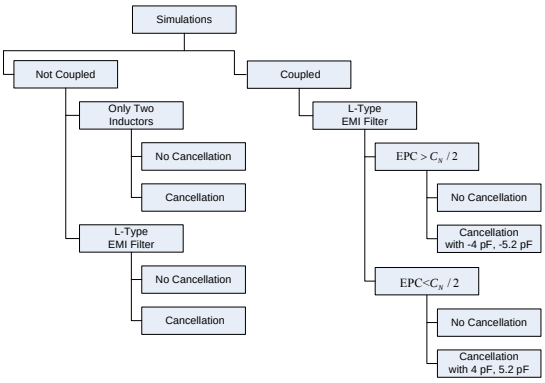

Figure 7. The simulation flowchart.

Fig. 7 shows the simulation flowchart to implement and verify the presented method.

A. *The inductors are not coupled*

In the first simulations, two inductors are not coupled, which are two inductors and L-Type EMI filter. The self-parasitic of two inductors is shown in Fig. 8 (a), L-Type EMI filter is shown in Fig. 8 (b) [1].

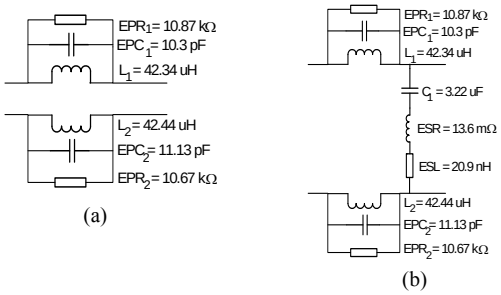

Figure 8. Self-parasitic capacitance of two inductor windings
(a) Two inductors (b) L-Type EMI filter.

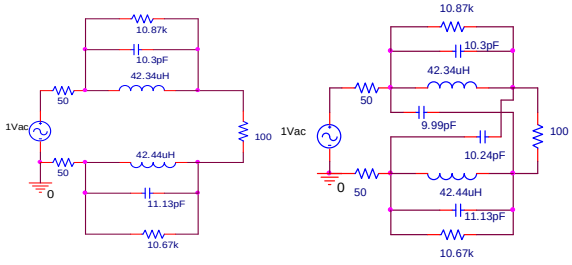

Figure 9. The simulation for canceled parasitic capacitance
(a) Two inductors without EPC cancellation
(b) Two inductors with EPC cancellation.

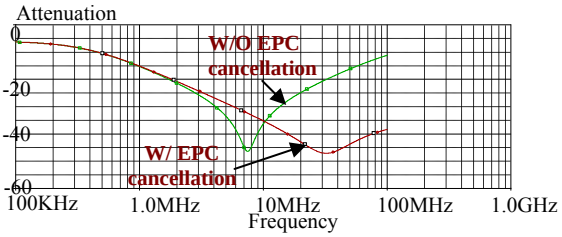

Figure 10. Improvement of inductor filtering performance at high frequencies due to the EPC cancellation for two inductors.

The two simulations for two inductors are inductor without parasitic capacitance cancellation and inductor with parasitic capacitance cancellation as shown in Figs. 9 (a)-(b), respectively. The capacitance of two cancellation capacitors is $N_1 = 9.99$ pF and $N_2 = 10.24$ pF, which are a little bit smaller than EPC_1 and EPC_2 [1].

In Fig. 10, the simulation results are compared between Figs. 9 (a)-(b). The two inductors have a resonance frequency about 7.5 MHz, which makes the inductor performance worse above 10 MHz. After EPC is canceled, the resonance moves to about 28 MHz. The result of this simulation is similarly with the experiment of [1].

The two simulations for L-Type EMI filter are inductor without parasitic capacitance cancellation and inductor with parasitic capacitance cancellation as shown in Figs. 11 (a)-(b), respectively. The one capacitor is used for L-Type EMI filter, simulated $C = 3.22$ μF, ESL=20.9 nH and ESR=13.6 mΩ [1].

In Fig 12, the result is compared between Figs. 11 (a)-(b). The L-Type EMI filter has a resonance frequency about 7 MHz. The filter's performance improves above 10 MHz. At the frequency about 670 KHz, it has a resonance frequency due to the series resonance (ESL) of C_1. The result of this simulation is still similarly with the experiment of [1].

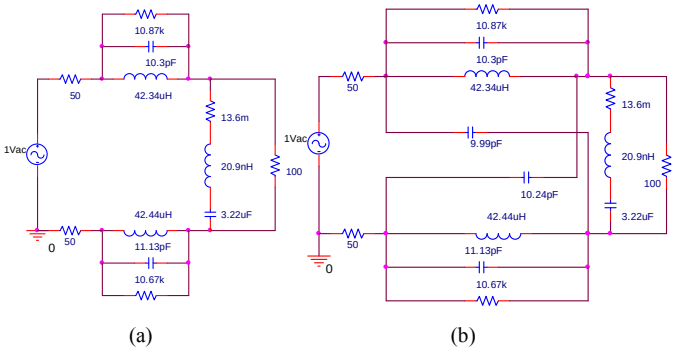

Figure 11. The simulation of L-Type EMI filter (a) L-Type EMI filter without EPC cancellation (b) L-Type EMI filter with EPC cancellation.

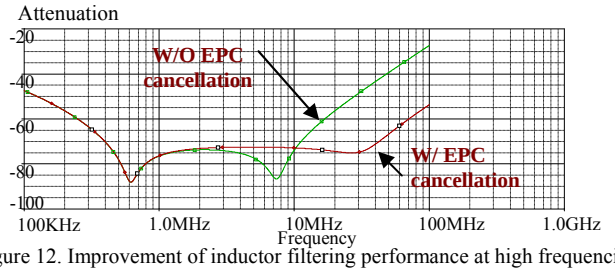

Figure 12. Improvement of inductor filtering performance at high frequencies due to the EPC cancellation for L-Type EMI filter.

B. *The inductors are coupled*

In the second simulation, the two inductors are coupled, which presents only L-Type EMI filter. The coupled inductor is located on one core. There are three kinds of parasitic capacitances in the inductor: turn-to-turn capacitance C_a, turn-to-core capacitance C_b, and winding-to-winding capacitance C_c as shown in Fig. 13. Their effects can be represented by EPC and C_N. EPC represents the effect of C_a and C_b. C_N represents the effect of C_c and C_b, i.e., the parasitic capacitance between two windings [1]. In the simulation each winding of the coupled inductor for L-Type EMI filter has an inductance of 20 μH. It is assumed that the inductance for one winding is L. Fig. 14 shows the self-parasitic capacitances of inductors are coupled. An L-Type EMI filter is built using one capacitor ($C = 477$ nF, ESL=18.5 nH and ESR=35.4 mΩ). The C_N is 14.8 pF [1].

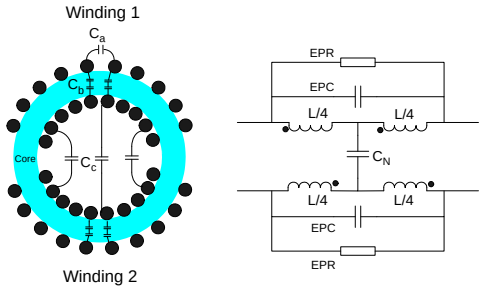

Figure 13. Parasitic capacitance between two coupled inductors winding (a) Inductor structure (b) Equivalent circuit.

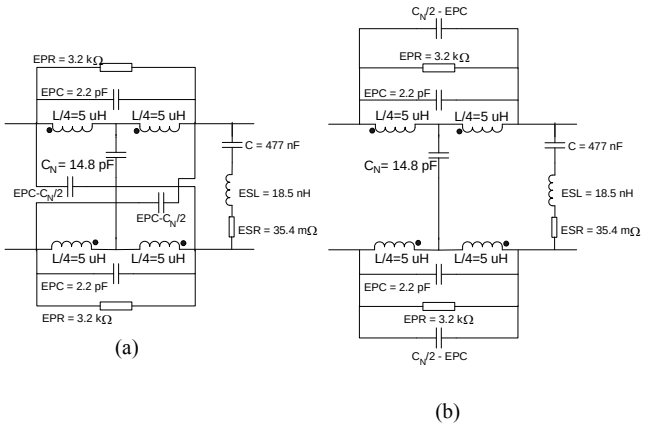

Figure 14. Self-parasitic capacitance of L-Type EMI filter (a) For $EPC > C_N/2$ (b) For $EPC < C_N/2$.

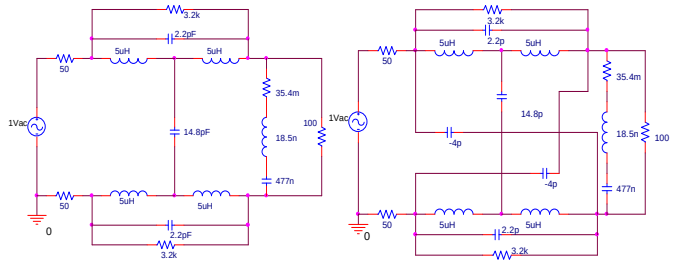
For $EPC > C_N/2$, the equivalent winding capacitance is positive, then two cancellation capacitors with a capacitance of -5.2 pF each need to parallel with two winding to cancel the winding capacitance 5.2 pF. The three simulations for L-type EMI filter are inductor without parasitic capacitance and inductor with −4 pF parasitic capacitance cancellation and inductor with −5.2 pF parasitic capacitance cancellation, as shown in Figs. 15 (a)-(c), respectively.

In Fig. 16, the simulation results are compared among Figs. 15 (a)-(c). The inductor of −5.2 pF EPC cancellation achieves the best performance above 5 MHz because the parasitic capacitance is almost canceled. For inductor with −4 pF, EPC cancellation is worse more than −5.2 pF EPC cancellation. For the inductor without EPC cancellation, the filter performance is worse above 5 MHz. This result is quite similarly with experiment [1].



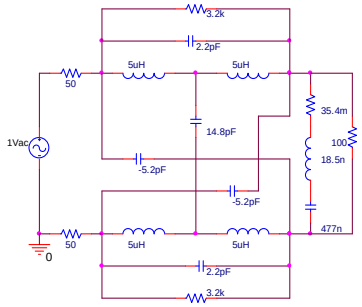


Figure 15. The simulation of L-Type EMI filter are coupled
(a) Inductor without EPC cancellation
(b) Inductor with −4 pF EPC cancellation
(c) Inductor with −5.2 pF EPC cancellation

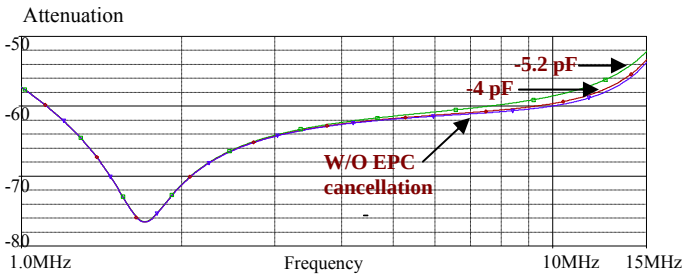

Figure 16. Improvement of inductor filtering performance at high frequencies for L-Type EMI filter.

For $EPC < C_N / 2$, the equivalent winding capacitance is negative, then, two cancellation capacitors with a capacitance of 5.2 pF each need to parallel with two winding to cancel the winding capacitance -5.2 pF. The three simulations for L-Type EMI filter are inductor without parasitic capacitance cancellation, inductor with 4 pF parasitic capacitance cancellation and inductor with 5.2 pF parasitic capacitance cancellation as shown in Figs. 17 (a)-(c), respectively.

In Fig. 18, the simulation results are compared among Figs. 17 (a)-(c). The inductor of 5.2 pF EPC cancellation achieves the best performance above 5 MHz because the parasitic capacitance is almost canceled. For inductor with 4 pF, it is worse more than 5.2 pF EPC cancellation. For the inductor without EPC cancellation, the filter performance is worse above 5 MHz. This result is in a good agreement with the experiment [1].

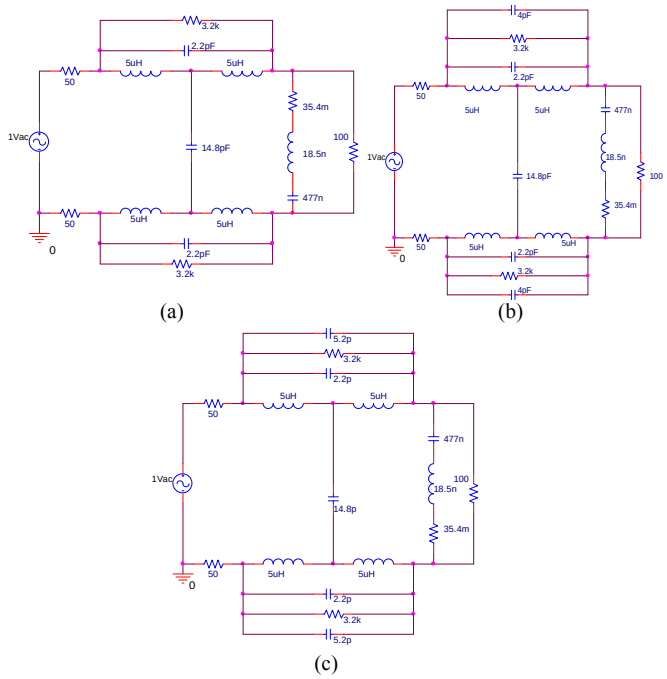

Figure 17. The simulation of L-Type EMI filter are coupled
(a) Inductor without EPC cancellation (b) Inductor with 4 pF EPC cancellation (c) Inductor with 5.2 pF EPC cancellation

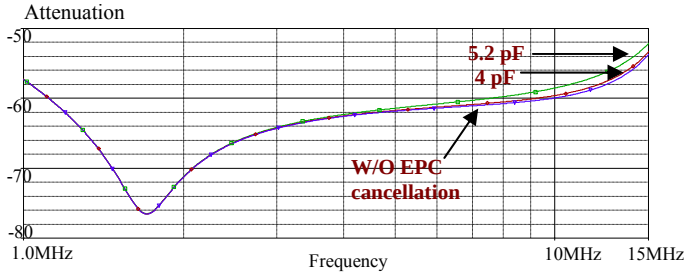

Figure 18. Improvement of inductor filtering performance at high frequencies for two inductors.

IV. Conclusion

The method and design of a mutual capacitance concept to cancel the effects of parasitic capacitance of inductors are discussed in this paper. This concept is verified by the simulation for ensuring Wang's proposed method [1]. With this concept, it can be applied for EMI filter design to efficiently improve its performance. Finally, it can be seen that the simulation are convenient, fastnesses, and high accuracy.

A Minimized Bandpass Filter Using Two-Layers With Aperture-coupled for Microstrip Slow-Wave Open-Loop Resonator

Apirada Namsang, Jaruek Jantree, and Prayoot Akkaraekthalin
Faculty of Engineering, King Mongkut's Institute of Technology North Bangkok
1518 Pibulsongkram Rd., Bangsue, Bangkok 10800, Thailand, email: japirada747@hotmail.com

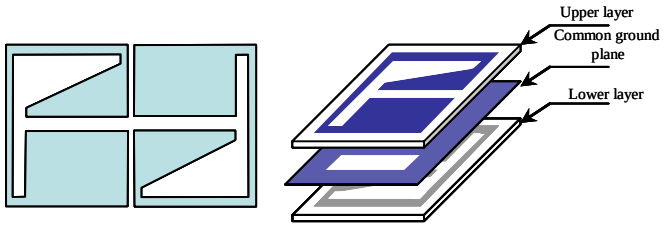
***Abstract*- This research proposes a new microstrip slow-wave open-loop resonator bandpass filter using a multilayer, resulting in size reduction. This filter structure consists of two microstrip layers supporting four resonators by inserting two apertures in a common ground plane. Each resonator is laid difference 180° with others. This filter has been designed at the operating frequency about 2.8 GHz, and a bandwidth of 80 MHz. The full-wave simulator IE3D has been employed to design the slow-wave open-loop resonator. The filter is not only sized reduction, but also low passband insertion loss and high return loss.**

I. INTRODUCTION

RF and microwave bandpass filters are presently required in wide applications of communication systems [1-2], for designing of compact and high performance microwave devices. The microstrip filter is one of the most important components, especially needs to reduce in size and norrrow-band.

Nevertheless there are several disadvantages of the planar filter. One of those is the spurious resonant frequency occurs at $2f_0$, and $3f_0$ where f_0 is the center frequency of a bandpass filter. Not only for suppress the resonant frequency but the high performance filter also need a wider upper stopband for reducing the interference from out of band signal. There are many ways which are proposed such as using microstrips parallel coupled lines to extend the electrical length and compensate the difference of the phase velocities [3]. The wiggly-line stripline filter is also another way of suppression the spurious frequency [4]. Besides, many bandpass filters using stepped impedance resonators to shift away the first higher order resonant frequency have been also proposed [5]. Otherwise planer cross-coupled filters have been proposed, which mostly based on open-loop microstrip resonators [6]. These filters provide the frequency transmission zero and also compact structure. As these best performances a microstrip slow-wave open-loop resonator [7] is designed by using asymmetrical capacitive load which including compact in size and a wide upper stopband.

Another disadvantage is the whole size of the planar filter which mostly implemented on a single microstrip is too large. To overcome the size problem there have been rapidly interested in multilayer structure devices [8-9]. This technique



(a) (b)

Figure 1. (a)Conventional micristrip slow-wave open-loop resonator bandpass filter and (b) micrstrip multilayer slow-wave open-loop resonator bandpass filter.

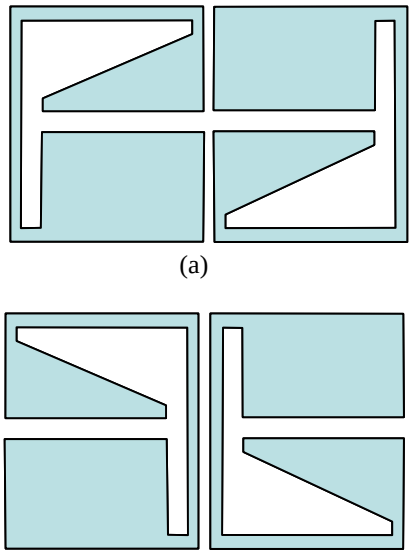
is based on the electric coupling, magnetic coupling and aperture coupling using square stepped impedance open loop resonators.

In this research, we proposed a technique to reduce size of the slow-wave filter but still keep the fundamental properties and also control spurious responses by adjusting the widths and gaps of the aperture. Figure1 (a) and (b) show the conventional and proposed multilayer structures, respectively. The proposed multilayer resonator structure consists of two resonators for the same area on upper layer and another two resonators are laid in the bottom one which the ground plane is inserted between them, resulting in 50% size reduction.

II. A MULTILAYER FILTER STRUCTURE

Figure2 shows the enlarge view of a stack of four resonators of the proposed bandpass filter. These resonators are placed on the external side of the two dielectric substrates that are separate by a common ground plane. Each resonator will be located 180° in different of layout together. Figure 2(a) shows two resonators which are on the upper layer, figure 2(b) shows others are on the lower layer. That means the layout of the upper layer resonator on the left hand side is placed as same as the lower layer resonator on the right hand side. By the way the layout upper layer resonator on the right hand side is placed as same as the lower layer resonator on the left hand side.

The upper and lower layers produce the essential couplings which influence to the characteristic of this filter. Such the upper layer generates the electric couplings that will appear between the resonators. Similarly, in the lower layer the



(a)

(b)

Figure 2. A view of the proposed multilayer bandpass filter (a) upper layer (b) lower layer

resonators are set in order to produce the magnetic couplings.

Besides that the aperture couplings between the two layers are certainly by inserting two identical apertures on the central common ground. The proposed multilayer bandpass filter uses slow-wave open-loop resonator bandpass filter located on the outer side of both dielectric substrates with a common ground plane in between and apertures on the common ground plane. These resonators are placed near each other with a specified space d.

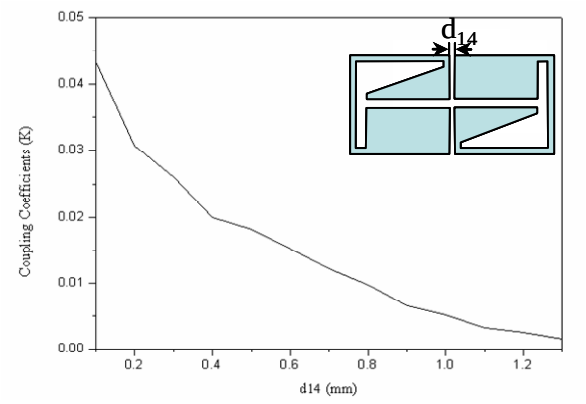
III. Design And Results

A. *Coupling structures*

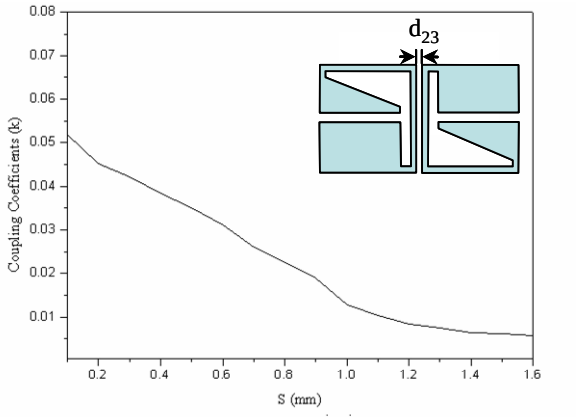
This proposed structure filter produces necessary couplings between adjacent resonators including electric coupling, magnetic coupling and aperture-coupling. Besides, filter designing always requires for good performances such as bandwidth so that it is essential to evaluate the coupling coefficient k between two adjacent resonators. The IE3D commercial electromagnetic simulation software, which is based on the method of moments and proven to be quite accurate in its prediction, has been used to simulate the frequency responses of the three basic coupling structures. In this method the factor of the electric and magnetic coupling depend on the distance between the two resonators on each layer. However, the mixed or aperture coupling will be depended on the dimension of aperture.

Due to the electric coupling behavior, in each structure can be sprit the two vital frequencies which are spirited off from the resonance situation. Then the coupling coefficient can be determined from them which extracted by following

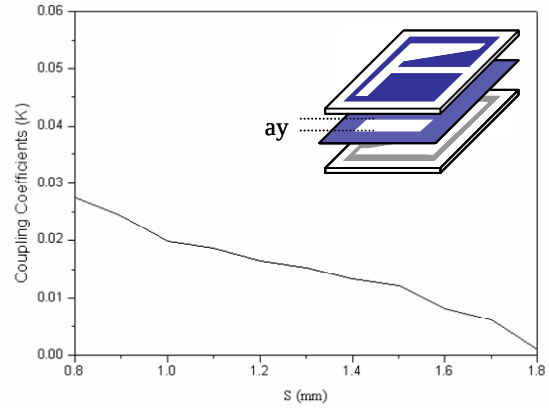
$$k_{ij} = \pm \frac{f_2^{\,2} - f_1^{\,2}}{f_2^{\,2} + f_1^{\,2}} \qquad (1)$$



(a)



(b)



(c)

Figure 3.Variation of the coupling coefficient K versus the distance s between two coupled resonators, (a) electric coupling (b) magnetic coupling and (c) mixed coupling.

where f_1 and f_2 are the sprit resonance frequencies. The external quality factor may be characterized by

$$Q_e = \frac{f_0}{f_{3dB}} \qquad (2)$$

where f_0 and f_{3dB} are the resonant frequency and 3 dB bandwidth of the input or output resonator when it alone is externally excited.

In this proposed filter is fabricated on a standard microwave substrate of GML 1000 substrate with a relative dielectric permittivity, ε_r of 3.2 and dielectric thickness, h of 0.762 mm from Roger Corp. Figure 3(a), (b) and (c) show an electric coupling, magnetic couplings, and aperture couplings respectively. The distance d between the two resonators is influence the variation of the coupling coeffient K.

B. Spurious suppression

This proposed resonator filter is also evaluated by IE3D microwave software to determine the characteristics of an asymmetry parallel coupled line diction to define the excitation of two mode of electromagnetic performance which known as odd- and even-mode[7]. Normally, when we can find the odd- and even-mode response of any resonator, the first spurious suppression can be obtained. In figure 4 shows an asymmetrical parallel coupled-line, supporting the odd- and even-modes. So we can basically predict how far that resonator filter can press the harmonic.

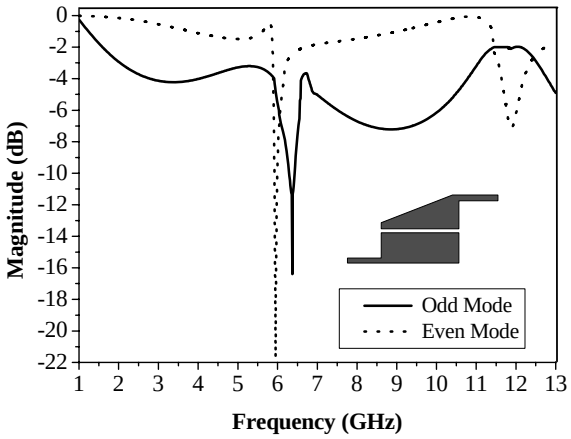


Figure 4. Frequency responses (S_{21}) of the asymmetrical triangle-rectangular coupler with odd- and even-mode excitations

C. Resonator Optimization

This proposed filter is a four resonator bandpass filter, which consists of the two slow-wave open-loop resonators on the top layer and others on the bottom layer which separate by the common ground plane. The filter has been then fabricated on a microwave substrate GML 1000 with a relative dielectric constant of 3.2 and a thickness of 0.762 mm. The value of gab g has been set to be 0.5 mm. In order to have a maximally flat passband bandwidth of 80 MHz (or the fractional bandwidth of FBW=28.6%) at f_0 = 2.8 GHz, the external quality factor Q_e as follows:

$$Q_e = \frac{g_1}{FBW} = 26.41017127 \qquad (3)$$

The coupling coefficients $K_{12} = K_{34}$ which are defined by the dimension of the apertures. By the ways the coupling coefficients K_{23} and K_{14} values are calculated by the space d_{23} and d_{14}. The values of the low pass prototype were synthesized with element values as $g_0 = 1$, $g_1 = 0.7553$, $g_2 = 1.2222$, $J_1 = 0.2576$, $J_2 = 0.9453$, so that the coupling coefficients can be calculated as follows

$$K_{12} = K_{34} = \frac{FBW}{\sqrt{g_0\, g_1}} = 0.02174 \qquad (4)$$

$$K_{23} = \frac{FBW \cdot J_2}{g_2} = 0.02204 \qquad (5)$$

$$K_{14} = \frac{FBW \cdot J_1}{g_1} = 0.003204 \qquad (6)$$

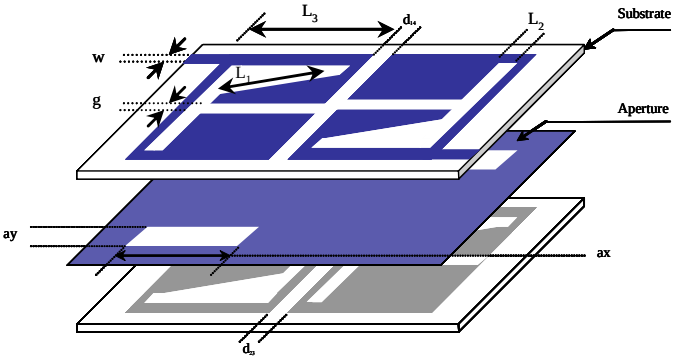

Figure 5. The multilayer open-loop resonator filter layout

Figure 5 illustrates the layouts of the multilayer open-loop resonator filter. Then the resonator layout parameters have been obtained in the following: L_1 = 8.09 mm, L_2 = 0.634 mm, L_3 = 8.889 mm, g = 0.501 mm, w = 0.381 mm and spacing d_{14} = 0.89 mm, d_{23} = 0.87 mm. The aperture dimension ay = 1.5 mm, ax = 5.94 mm.

Figure 6 shows a photograph of the fabricated filter using a proposed filter. Figure 7(a) shows the measurement and simulated response which is being analytical from the IE3D software. The measured center frequency is 2.75 GHz with insertion loss approximately -3 dB. The passband return loss is greater than 10 dB. Figure 7(b) illustrates a wide upper stopband. We can see the spurious frequencies are rejected more than 25 dB up to 10 GHz.

IV. CONCLUSION

We have presented a technique for reducing size of a bandpass filter by using the multilayer structure of cross coupled slow-wave open-loop resonator with apertures. This bandpass filter has been designed at the high frequency about 2.8 GHz. Otherwise this filter is not only compact 50% in size

but also having a wider upper stopband. This filter can suppress spurious response and move it far away longer than 10 GHz. The filter has been optimized using IE3D microwave software.

***Abstract*- This paper investigated wideband coplanar waveguide (CPW) fed rectangular slot antenna with rectangular planar patch and slot tuning. A rectangular slot antenna is excited by a 50 ohm CPW with slot tuning on rectangular planar patch for wireless applications. By adjusting size of rectangular planar patch and of slot tuning on rectangular planar patch, can easily achieve a wideband. The proposed antenna is designed to operate from 1.38 to 6.04 GHz which is suitable for applications in WLAN (Wireless Local Area Network) according to IEEE 802.11 a/b/g standards and covered the WiMAX (Worldwide Interoperability for Microwave Access, IEEE 802.16e). The characteristics of antenna are proposed and analyzed for bandwidth, return loss, input impedance and VSWR. The simulation results are analyzed by IE3D Zeland software.**

I. INTRODUCTION

Recently, there is growing research activity on multi-frequency and broadband and wideband antennas for various wireless communication applications such as WLAN (Wireless Local Area Network) or WiMAX (Worldwide Interoperability for Microwave Access. In particular, a great interest in coplanar waveguide (CPW) fed slot antenna has been presented in the paper because the CPW fed slot antennas have the advantage of wide bandwidth, simplest structure and easy integration with active devices [1]. The CPW fed slot antennas have been designed for wideband applications by rectangular and square slot and enhance bandwidth by optimizing a tuning stub [2, 3, 4].

In this paper, we propose a CPW fed slot antenna for wideband application in WLAN communication and WiMAX. Owing to the slot tuning on rectangular planar patch inset around the side edge of the rectangular slot antenna, a new resonant frequencies can be excited and enhance the operating bandwidth of the wideband by adjusting parameter of slot tuning on rectangular planar patch, which simulation covers the bandwidth of 1.38 to 6.04 GHz is enough for wireless communication. Detail of the proposed CPW fed slot antenna designs are described, and simulation results for obtained wideband performance are presented by using IE3D Zeland software.

II. ANTENNA STRUCTURE

Figure 1, shows the structure of the proposed CPW-fed rectangular slot antenna with slot tuning on rectangular planar patch at designed frequency 1.5 GHz. The slot antenna is on FR4 substrate of dielectric constant 4.5 (ε_r) and substrate of thickness 1.6 mm (h). The dimension of dielectric substrate is 53x61.5 mm^2. The proposed antenna consists of rectangular slot has a length Lx = 44.8 mm and Ly = 25.5 mm. A 50 ohms coplanar waveguide with gap width S = 0.5 mm and centre conductor width Wc = 5.4 mm and the end of CPW feed line connected to rectangular planar patch of dimensions width Wx = 27.8 mm and Wy = 15.5 mm. The both slot tuning etched at the middle of rectangular planar patch, the spacing between rectangular planar patch and edge of the ground plane is G = 1.6 mm. The slot tuning consist of four parameters which three parameters of slot tuning: Lh, Lw and Ls, affect the wideband operation other one is Lv fixed to 2 mm. The characteristic of the proposed antenna and details of designing are discussed in the following section.

The guide wavelength is given by

$$\lambda_g = \frac{c/f}{\sqrt{\varepsilon_{eff}}} \tag{1}$$

Where ε_{eff} is an effective dielectric constant which can be computed by using the following equation.

$$\varepsilon_{eff} \approx \frac{\varepsilon_r + 1}{2} \tag{2}$$

In this case, ε_{eff} = 2.75 and λ_g = 120.6 mm, and dimension of rectangular slot antenna in length and width (Ly and Lx) is about $0.58\lambda_g$ ($Lx = 0.37\lambda_g$ and $Ly = 0.21\lambda_g$).

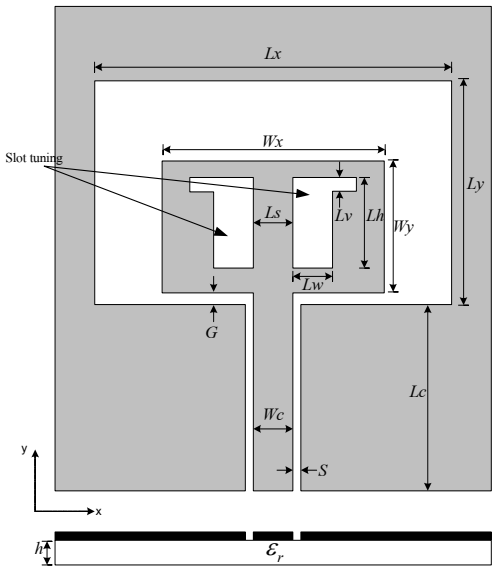

Figure 1. Structure of the proposed antenna.

III. SIMULATION RESULTS

The proposed antenna was designed and studied for bandwidth enhancement. The theoretical analysis was performed using the IE3D simulate software package of Zeland [5]. The CPW feed line is designed with the centre conductor width *Wc* = 5.4 mm, coplanar waveguide with gap width *S* = 0.5 mm, and length CPW feed line of *Lc* = 26 mm for match with 50 Ohms characteristic impedance. There are three designs for show the enhancement of this antenna, the first is CPW fed rectangular slot antenna, second is rectangular planar patch inside of the slot, and third is slot tuning inside of the planar patch. The proposed design can be further enhanced by rectangular conductor patch and with slot tuning on rectangular planar patch. The main proposed of this paper is to show the effect of adjusting three parameters: *Lh*, *Lw* and *Ls* of slot tuning. The result of S11 in three designs are shown in Figure 2, which fixing value of the parameters: *Lx, Ly, Wx, Wy, G, Wc, S*, *Lv* and *Lc* as a first step. The initial value of three parameters of slot tuning of *Lh* = 11 mm, *Lw* = 2 mm and *Ls* = 5.4 mm are proposed for begin adjusting. From Figure 2, the bandwidth of proposed antenna will be increased when using conductor stub tuning (rectangular planar patch) and slot tuning. For more bandwidth enhancement from Figure 2, the adjusting of three parameters will be considered in next step.

A. Effect of Adjusting Lh of Slot Tuning

In this case, we fixed *Lw* = 2 mm, *Ls* = 5.4 mm and vary the length *Lh* of slot tuning to 11 mm, 11.3 mm, 11.5 mm and 12 mm, respectively. The effect on the resonant frequencies and bandwidth are investigated as shown in Figure 3. Its shown that the bandwidth at return loss -10 dB about 4 GHz, the lowest resonance frequency of each value of *Lh* is same but highest resonance frequency is shift down when *Lh* is increased. From Figure 3, the best matching for wideband is at *Lh* = 12 mm, which return loss is 50 dB at ~4.2GHz.

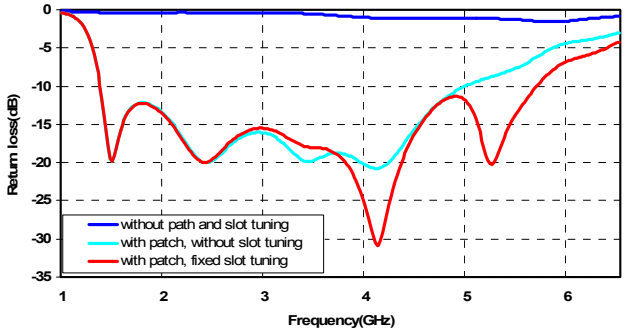

Figure 2. Comparison return loss of three designs.

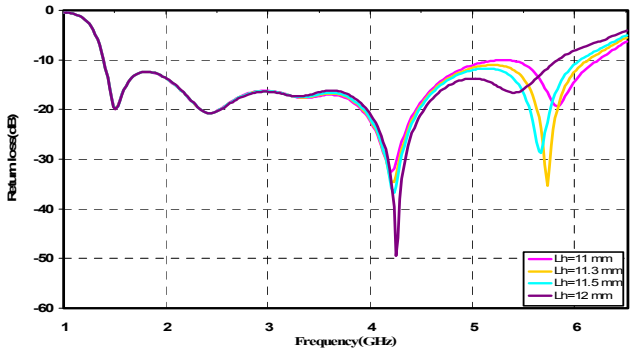

Figure 3. Simulation return loss for difference *Lh*.

B. Effect of Adjusting Lw of Slot Tuning

The effect of the width *Lw* of slot tuning on return loss is considered. Herein, the *Lw* is chosen to 3.7 mm, 4.2 mm, 4.7 mm and 5.7 mm, while *Lh* = 11.5 mm, *Ls* = 5.8 mm are fixed.

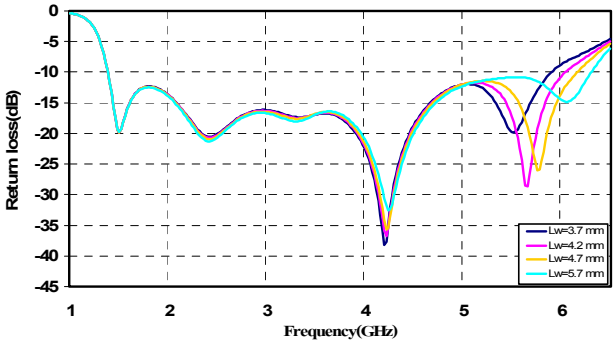

Figure 4. Simulation return loss for difference *Lw*.

The typical simulation results are shown in Figure 4, when we focus to the high resonance from 4 to 6 GHz, it can be found that the resonance frequency near 4 GHz is slightly

chanced but the resonance frequency near 6 GHz is shift up when value of *Lw* is increased and wider bandwidth.

C. Effect of Adjusting Ls of Slot Tuning

The effect of distance between both slot tuning (*Ls*) on the return loss is considered by vary values of *Ls*: 4.8 mm, 5.8 mm, 6.2 mm and 7 mm, respectively, while *Lh* = 11.5 mm and *Lw* = 4.2 mm, as shown in Figure 5. The resonance frequencies slightly changed and return loss is much change.

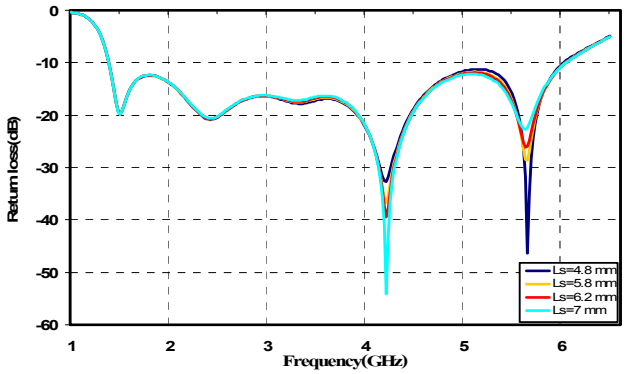

Figure 5. Simulated return loss for difference *Ls*.

D. Characteristic of Return Loss

We optimized and investigates the effect of adjusting three parameters of the antenna for enhance bandwidth covers IEEE 802.11a/b/g (2.4-2.4835GHz, 5.15-5.35GHz and 5.725-5.875GHz) WLAN applications and WiMAX (2-6 GHz). Finally, the dimension of slot tuning is *Lh* = 11.5 mm, *Lw* = 4.2 mm and *Ls* = 4.8 mm for sufficient choosing. Figure 6, shown the frequency band and maximum bandwidth coverage at 1.38 GHz to 6.04 GHz which all of parameters are shown in Table 1.

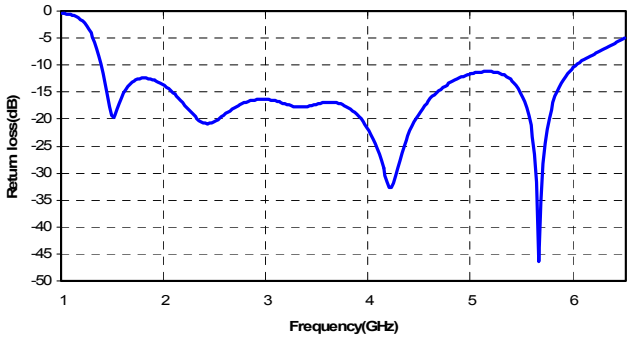

Figure 6. Simulated S_{11} of the proposed antenna.

E. Characteristic of Input Impedance

The input impedance Z_{in} is the complex number, which fined out by using the S_{11} parameter and characteristic impedance Z_o of transmission line. The characteristic of input impedance for this slot antenna is shown in Figure 7.

TABLE 1
Parameters of the proposed antenna designs.

	without patch and slot tuning (mm)	with patch, without slot tuning (mm)	with patch and slot tuning (mm)
Lx	44.8	44.8	44.8
Ly	25.5	25.5	25.5

IV. CONCLUSION

This paper presented the bandwidth enhancement of CPW fed slot antenna by rectangular conductor patch and slot tuning on rectangular planar patch. This slot antenna easy to fabrication and can achieved the wideband from frequency range 1.38 – 6.04 GHz coverage IEEE 802.11 a/b/g standard (2.4-2.4835 GHz, 5.15-5.35GHz and 5.725-5.875GHz) for WLAN and WiMAX (IEEE 802.16e, 2-6 GHz).

***Abstract*- This paper presents elliptical patch antenna that radiates unidirectional beam with circular polarization. This antenna is proposed for installing at the reader of the Radio Frequency Identification (RFID) at Ultra High Frequency (UHF) band. The center frequency is 923 MHz with the bandwidth from 920 MHz to 925 MHz. The antenna structure is simple because we use the single feed for circular polarization. The prototype antenna was fabricated to measure the characteristics. The pattern is unidirectional pattern with directivity around 8.93 dBi and axial ratio of 1.88 dB at the center frequency. The obtained bandwidth is 15 MHz.**

I. INTRODUCTION

At present, Radio Frequency Identification (RFID) system becomes very popular due to their usefulness in many applications such as identification, logistics and many others [1]. The antenna designs for both readers and tags are hot research topics. The operating frequency depends on different applications. The ultra-high frequency band is desired for long range applications. The antenna at reader plays a vital role in communication between the reader and the tags. The antennas that can communication with various tag orientations is desirable. Therefore, the antenna radiating the circular polarization is needed to cope with this problem [2]-[4]. In addition, for convenient installation the flat structure is required [5]-[10]. In literature, there are many researches involving with flat structure with circular polarization [2]-[10]. However, all of them focus on the design at microwave frequency that printed circuit board (PCB) is convenient to use for microstrip antenna fabrication with many configurations. To apply the similar concept to the UHF band, the authors proposes to use elliptical patch antenna with single feed to radiate circular polarization. The antenna is designed to achieve the unidirectional beam to direct at the tag direction. The structure is made of metallic plate with air substrate to avoid dielectric loss. The structure is flat with the feeding structure is easy. The antenna is expected to use for reader of RFID system.

II. ANTENNA STRUCTURE

The antenna structure is composed of three metallic plates as shown in Fig.1. The top plate is cut as the elliptical geometry with the major and minor axes of u_x and u_y, respectively. The middle plate is rectangular configuration with two opposite truncated corners whereas the remained two corners are not truncated. The length and the width of the rectangular one are v_x and v_y, respectively. The radius of the truncated corner is denoted by r. At the non-truncated corner, there are two square holes of the size s_h. The distance between the center of the hole and the corner is d. The bottom plate acts as the ground with the length and width of w_x and w_y, respectively. This structure is excited by the linear electric probe. The spacing between the bottom plate and the middle plate and the middle plate and the top plate are t_1 and t_2, respectively. The feeding location is x_p and y_p offset from the top and the right sides, respectively.

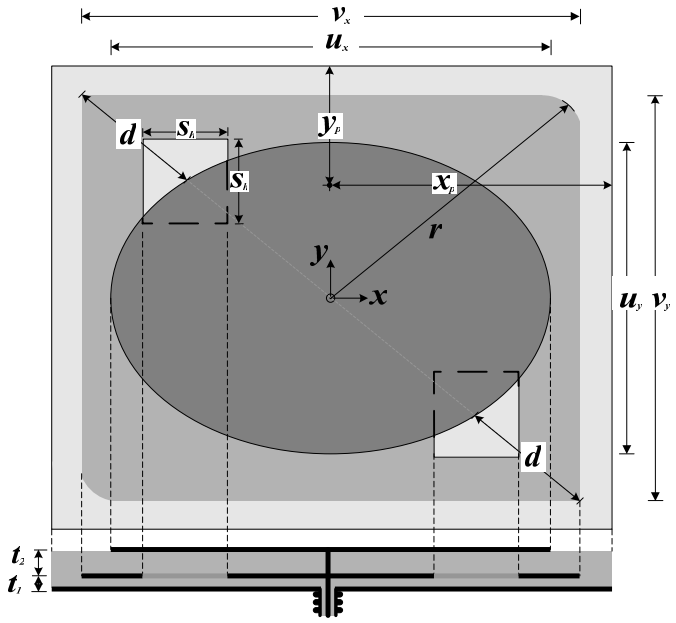

Figure 1. Antenna Structure

III. PARAMETRIC STUDY

In order to find the suitable parameters to obtain the unidirectional pattern with the circular polarization, the hole and the patch sizes must be varied. The other parameters have the size corresponded the operating frequency scaled from the references [2]. The initial antenna parameters are tabulated in Table 1.

Table1 Antenna Parameters

Parameters	Electrical Size	Physical Size at 923 MHz
u_x	0.44λ	14.21 cm
u_y	0.29λ	9.59 cm
v_x	0.58λ	18.80 cm
v_y	0.47λ	15.40 cm
r	0.25λ	8.20 cm
t_1	0.008λ	2.60 mm
t_2	0.034λ	11.10 mm
d	0.17λ	5.38 cm
x_p	0.34λ	10.90 cm
y_p	0.16λ	5.25 cm

The variation of axial ratios versus the hole size is shown in Fig.2. It is found that the suitable hole size with minimum axial ratio is 3.38 cm.

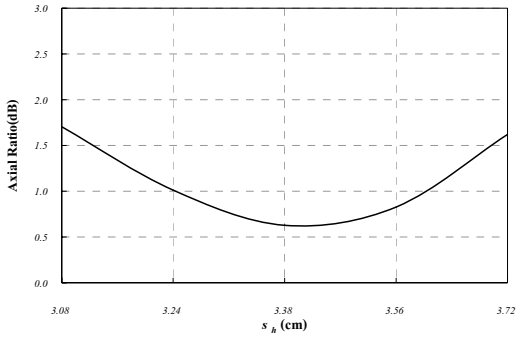

Figure 2. Axial ratio versus s_h

The axial ratio of the antenna in xz-plane for different hole sizes is illustrated in Fig.3. It is found that the axial ratio is lowest at angle of zero degree. However, when the angle is 90 degree offset, the axial ratio becomes very high. So, the circular polarization is significantly obtained at the angle of zero degree.

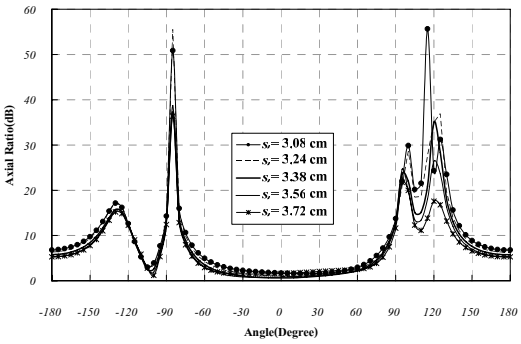

Figure 3. Axial ratio versus angle for different s_h

The magnitude of S_{11} as a function of frequency for various hole sizes is shown in Fig.4. It is obvious that the hole size affects the resonant frequency and level of $|S_{11}|$. To obtain the resonant frequency of 923 MHz with $|S_{11}|$ better than -10 dB, the hole size of 3.38 cm is selected.

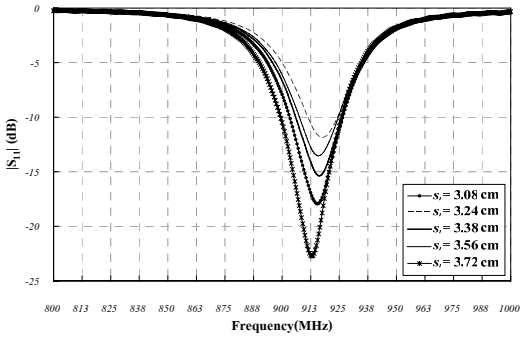

Figure 4. Magnitude of S_{11} versus frequency for different s_h

The axial ratio as a function of additional patch size is shown in Fig.5. The other parameters are the same as Table 1. It is evident that δ = 1.17 cm achieves the minimum axial ratio.

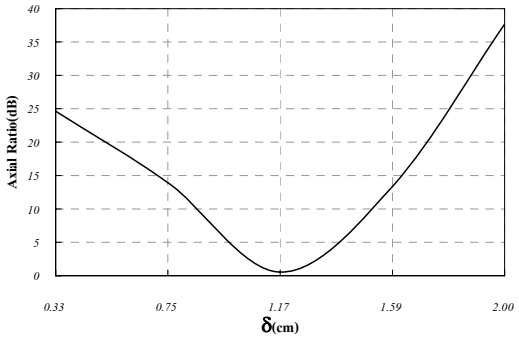

Figure 5. Axial ratio versus δ

The axial ratio in xz-plane for different additional patch sizes is shown in Fig.6. It is found that the minimum axial ratio is accomplished at angle of zero degree. When comparing among different δ, δ = 1.17 cm has the lowest axial ratio. This parameter is used for the guideline of the antenna design.

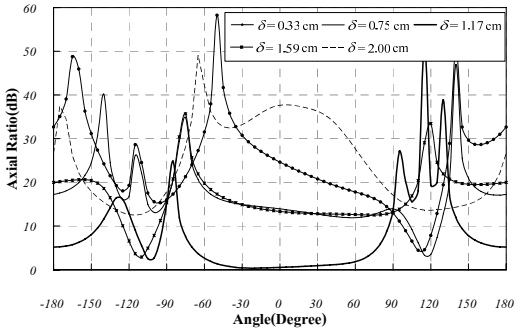

Figure 6. Axial ratio versus angle for different δ

In order to clarify the matching condition of the antenna for various δ, the magnitude of S_{11} for different δ is illustrated in Fig. 5.

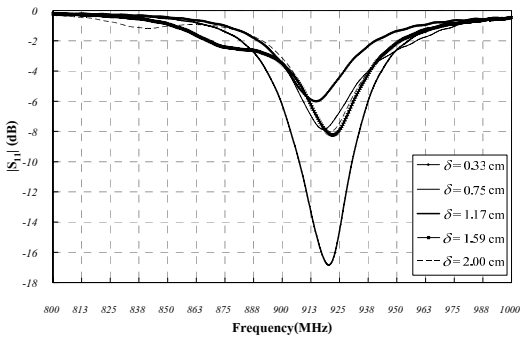

Figure 7. The magnitude of S_{11} versus frequency for different δ

The directivity of the antenna as a function of the frequency is shown in Fig.8. As expected, the directivity is increased when the frequency is higher because the dimension of the antenna per wavelength is larger. At the center frequency of 923 MHz, the directivity is 8.93 dBic.

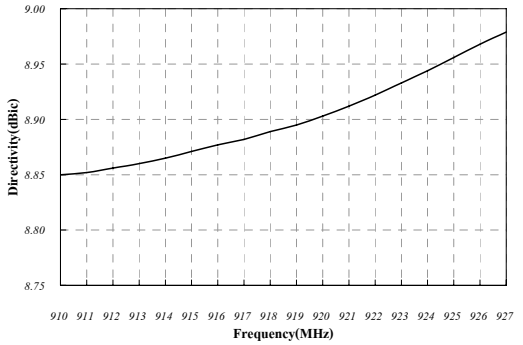

Figure 8. Directivity versus frequency

The axial ratio as a function of the frequency is shown in Fig.9. It is evident that the minimum axial ratio is occurred at 918 MHz. However, along the frequency range of 910-926 MHz, the acceptable axial ratio of less than 3 dB is accomplished. At the frequency of 923 MHz, the axial ratio is 1.88 dB.

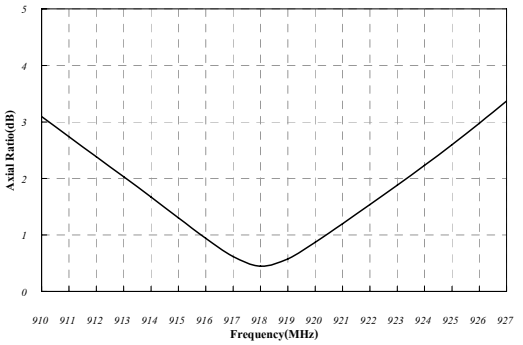

Figure 9. Axial ratio versus frequency

The axial ratio as a function of angle in xz- and yz-planes is shown in Fig.10(a) and Fig.10 (b), respectively. We have changed the frequency at 913, 917, 921 and 925 MHz. It can be seen that the axial ratio is slightly different for various frequencies. When comparing among the different angles, it is found that the angle of zero degree yields the minimum axial ratio.

IV. MEASURED RESULTS

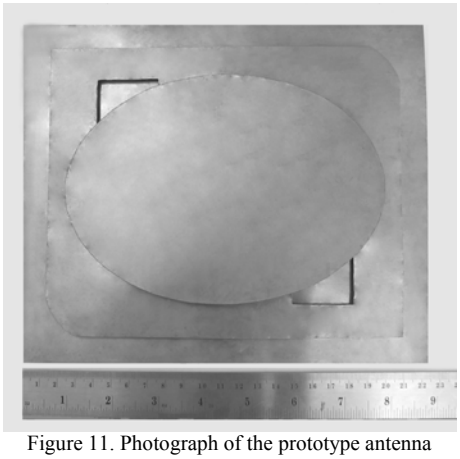

Figure 11. Photograph of the prototype antenna

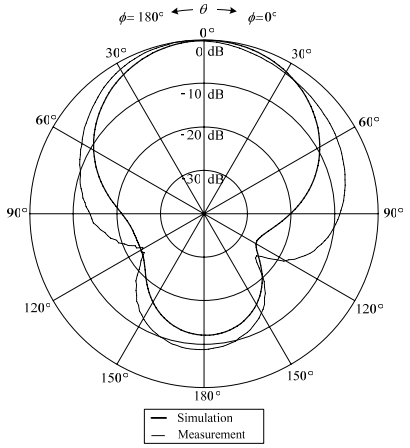
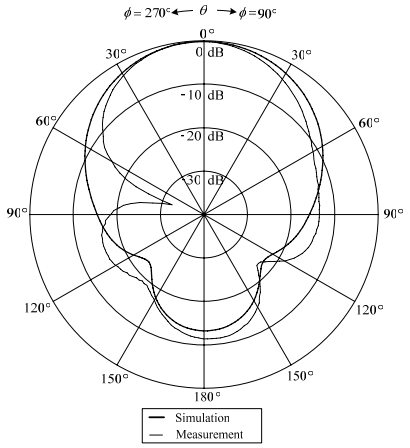
In order to verify the principle, the prototype antenna was fabricated to operate at the frequency of 923 MHz as shown in Fig.11. The physical dimension is shown in Table 1. The measurement of radiation pattern is set up at the frequency of 923 MHz. The radiation pattern in xz- and yz- planes are plotted and compared with the simulated results as shown in Fig.12(a) and Fig.12(b), respectively. It is seen that the results are reasonable agreement. The unidirectional is obtained. The measured beamwidths in xz- and yz- planes are 100 and 70

degrees, respectively. The measured front-to-back ratio in both planes is 12.7 dB.



(a) xz - plane



(b) yz – plane

Figure 12. Simulated and measured patterns

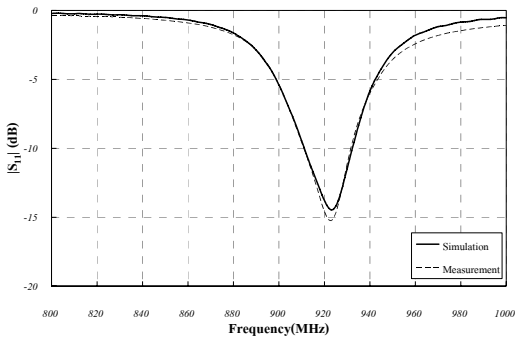


Figure 13. Simulated and measured magnitude of S_{11}

The magnitude of S_{11} as a function of frequency from simulation and measurement is disposed in Fig.13. It is found that the simulated and measured results agreed very well. The obtained impedance bandwidth of $|S_{11}|$ better than -10 dB is 2.2 % (912 - 932 MHz).

V. Discussions And Conclusions

The UHF-RFID antenna is proposed in this paper using the elliptical patch antenna to radiate the circular polarization. The antenna structure is simple because it need only single feeder and it is free from dielectric loss. The parametric study of the antenna is presented. It is obvious that the antenna radiates unidirectional beam with the beamwidth in xz- and yz- planes are 100 and 70 degrees, respectively. The axial ratio is 1.88 dB and the directivity is 8.93 dBic, respectively. From the results, it can confirm that this antenna can be used as the reader antenna of the UHF-RFID system.

***Abstract*- This paper presents the parametric study of a vertically polarized concentric circular ring antenna above the reflector for high gain applications. The proposed antenna is designed to achieve unidirectional pattern with high gain for the point-to-point communication application in wireless Local Area Network (WLAN). The operating frequency of this antenna is 2.45 GHz. The CST software based on FIT (Finite Integral Technique) is used as the simulation tool for investigating the antenna characteristics. From the simulation, the antenna bandwidth, frequency range and gain are 28.30%, 2.00-2.66 GHz and 9.19 dBi, respectively. Moreover, the good radiation characteristics with vertical polarization and front-to-back ratio better than 20 dB are obtained in both E-plane and H-plane.**

I. INTRODUCTION

It is well-known that the antenna is a significant part of wireless system to make the communication successfully. The conventional antenna for the wireless Local Area Network communication system radiates the omnidirectional beam. However, for some specific application of the long range service area such as the point-to-point communication between the buildings, the unidirectional antenna is preferred. Generally, the unidirectional antenna with the high gain, low side lobe level and narrow beamwidth is desirable. Thus, many researches have continuously developed the unidirectional antennas as published in [1]. Usually, the unidirectional beam can be obtained by using microstrip fundamental mode [2], horn antenna [3], reflector antenna [4] and many others. Moreover, the unidirectional antenna can be achieved by using some specific antenna that is arranged to from the array configuration [5]-[6]. Most unidirectional antenna has complicated structure with the expensive material. However, the structure of a concentric circular ring antenna above the reflector is simple and cost-effective.

Historically, the probe excited circular ring is designed to radiate the bidirectional pattern [7]. The unidirectional beam is carried out by placing the antenna above the reflector or ground plane. To realize the unidirectional pattern, the reflector should be placed near one side of the ring aperture [8]. From the previous work we found that the side lobe level is not good and directivity is not so high. But, the proposed antenna has an impedance bandwidth (2:1 VSWR) of 28.30%. The centre frequency is 2.45 GHz, and the obtained frequency range is 2.00-2.66 GHz. From the simulation, the concentric circular ring antenna above the reflector has the unidirectional pattern with the gain of 9.19 dBi. The polarization is vertically linear polarization, the front-to-back ratio in both E-plane and H-plane is better than 20 dB. Moreover, the design of this antenna is simple, and the fabrication uses the low cost materials. Therefore, this antenna is interested for utilizing in the point-to-point wireless Local Area Network communication system.

The content of this paper are divided into five sessions. In section II, the antenna structure is described. Then, the parametric study and conclusion of antenna parameter are presented. The last session is conclusion.

II. ANTENNA STRUCTURE

The structure and design of the antenna is easy and straightforward. For the specified operating frequency, a choice of the ring radius is first chosen to achieve the condition that only the dominant mode can be propagated inside the cylindrical waveguide. The structure of a concentric circular ring antenna above the reflector for high gain application consists of a linear electric probe of the length *l* aligned along the *y* axis, and the distance from probe to reflector is *h*, and it is surrounded by an inner ring of the radius *a*. The radius of an outer ring is *b*; the lengths of inner and outer circular ring are *t* and *d*, respectively. The distance between inner and outer circular ring is supported by the post of the length *p*. The traveling wave along *z* axis is accomplished by using an electric probe fed in the radial direction as shown in Fig.1. It is noted that the probe is shielded by dielectric rod of the length *l*/2.

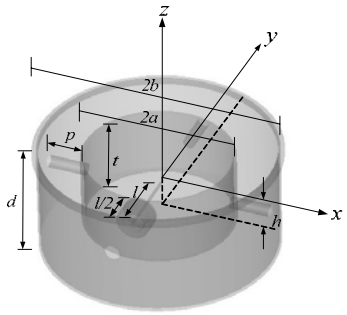

Fig.1 A concentric circular ring antenna above the reflector

The antenna was made from two material types, i.e. the outer circular ring and the reflector are made of aluminum and the inner circular ring is made of brass. The initial parameters for the parametric study are tabulated as shown in Table 1.

Table1 Antenna Parameters

Parameters	Electrical Size	Physical Size
a	0.59λ	72.71 mm
b	0.95λ	116.59 mm
l	0.26λ	33.00 mm
h	0.26λ	32.00 mm
t	0.29λ	35.53 mm
d	0.43λ	53.43 mm
p	0.17λ	21.94 mm
ε_r (dielectric constant)	10	10
Location of the Probe	$\rho = a$, $\phi = 90^o$, $z = 0$	

III. PARAMETRIC STUDY

A concentric circular ring antenna above the reflector is designed to operate at frequency of 2.45 GHz. The parametric study of six parameters is investigated in this section, i.e. the inner ring radius (a), outer ring radius(b), length of inner ring (t), length of outer ring (d), distance from probe to reflector (h), and probe length (l), respectively.

A. Effect of radius and length of inner ring

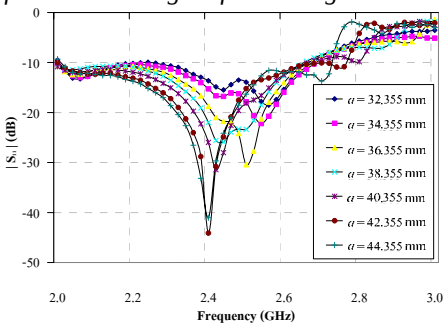

Fig.2 Frequency response of return loss as a function of inner ring radius

Figure 2 shows the frequency response of return loss as a function of inner ring radius. The different radii of inner ring are analyzed whereas all other parameters are fixed as following Table 1. The radius of inner ring affects to the front-to-back ratio as illustrated in Fig.3. From Fig.3, it is obvious that a of 42.355 mm is the suitable value of inner ring radius because it provides the optimum front-to-back ratio.

Moreover, the influence of the length of inner ring (t) is studied by fixing the radius of inner ring at 42.355 mm for simulation. The different lengths of inner ring are analyzed from 13.765 mm to 21.765 mm. Figure 4 and Figure 5 show the frequency response of return loss and front-to-back ratio as a function of inner ring length, respectively. From the results it is obvious that the inner ring length (t) of 17.765 mm is suitable for the antenna design because the best front-to-back ratio is obtained.

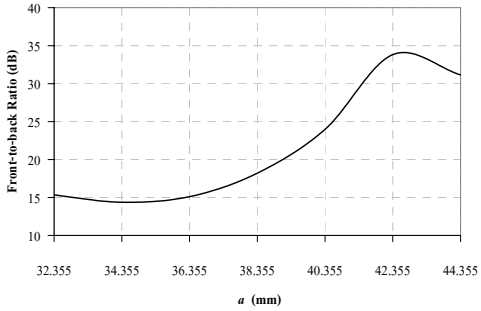

Fig.3 Front-to-back ratio as a function of inner ring radius

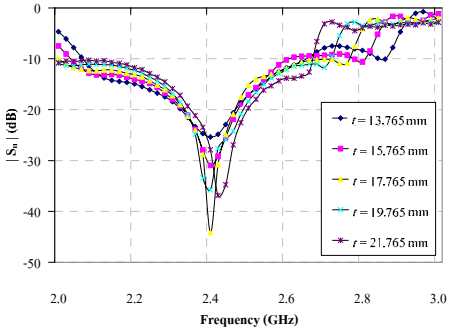

Fig.4 Frequency response of return loss as a function of inner ring length

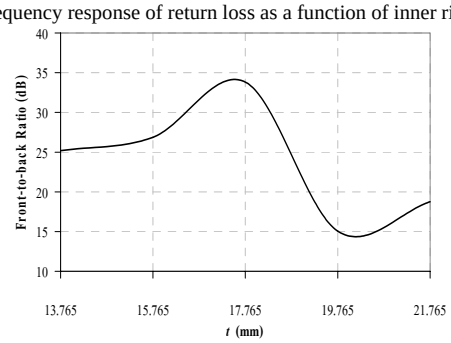

Fig.5 Front-to-back ratio as a function of inner ring length

B. Effect of radius and length of outer ring

The effects of different radii of outer ring are investigated from 54.295 mm to 62.295 mm while the radius and length of inner ring is fixed at 42.355 mm and 17.765 mm, respectively. Figure 6 and Figure 7 shows the frequency response of return loss as a function of outer ring radius and front-to-back ratio for various radii of outer ring. From the simulated results it is obvious that the outer ring radius (b) of 58.295 mm is suitable for the antenna design because the front-to-back ratio is the maximum at 58.295 mm as can be seen in Fig.7.

Furthermore, the simulation is performed to study the influence of the outer ring length by fixing a=42.355 mm, t=17.765 mm and b=58.295 mm while the outer ring lengths are varied from 45.43 mm to 57.43 mm. From Fig. 8, the outer ring length is not much affected to the return loss. Figure 9 shows the front-to-back ratio for various outer ring lengths. From the simulated results, it is obvious that the outer ring length (d) of 47.43 mm is the suitable for the antenna design.

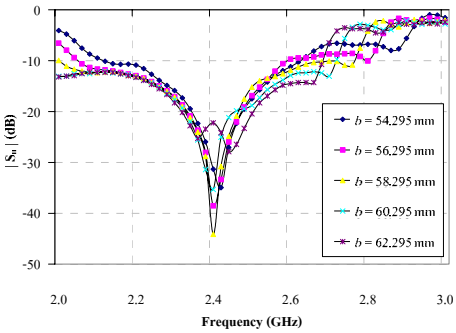

Fig.6 Frequency response of return loss as a function of outer ring radius

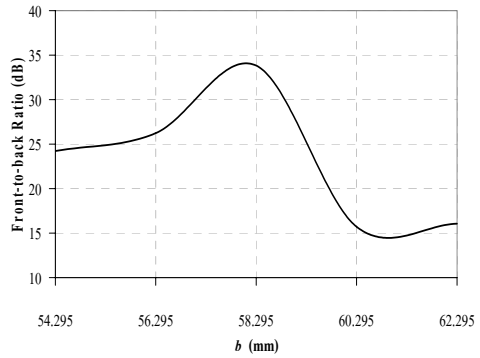

Fig.7 Front-to-back ratio as a function of outer ring radius

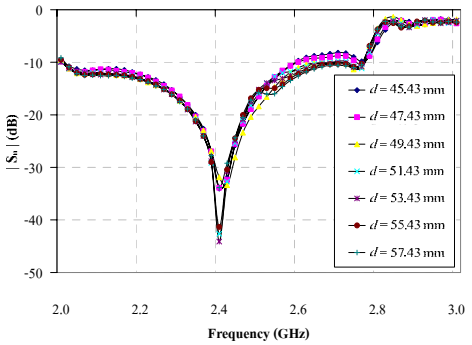

Fig.8 Frequency response of return loss as a function of the outer ring length

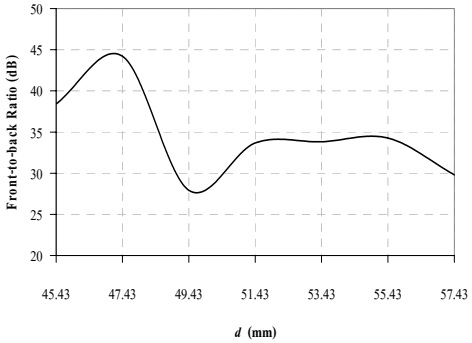

Fig.9 Front-to-back ratio as a function of outer ring length

C. Effect of distance from probe to reflector

In this section, the simulation is conducted to study the antenna characteristics of the distance from probe and reflector by using *a*=42.355 mm, *t*=17.765 mm, *b*=58.295 mm and *d*=47.43 mm. The distances from probe to reflector are investigated from 28 mm to 40 mm. The frequency response of return loss as a function of distance from probe to reflector is shown in Fig.10. The front-to-back ratio for various distances from probe to reflector is shown in Fig.11. From the simulated results, the distance from probe to reflector (*h*) of 32 mm is suitable for the antenna design.

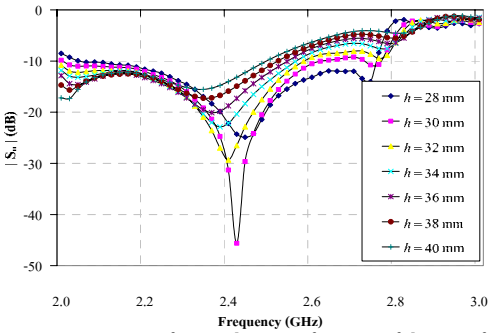

Fig .10 Frequency response of return loss as a function of distance from probe to reflector

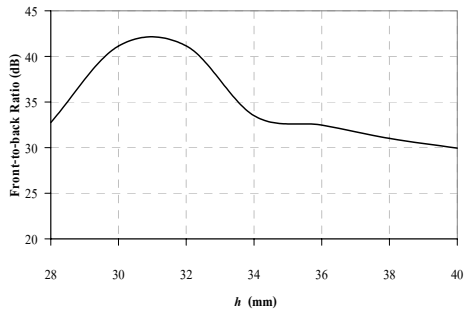

Fig.11 Front-to-back ratio as a function of distance from probe to reflector

D. Effect of probe length

The influence of the probe length (*l*) are also studied by fixing *a*=42.355 mm, *t*=17.765 mm, *b*=58.295 mm, *d*=47.43 mm, and *h*=32 mm. The probe lengths are investigated from 29 mm to 45 mm. From the simulation, it is found that the probe length (*l*) have much influence to return loss as illustrated in Fig.12. From the simulated results, the probe length of 33 mm is chosen for the antenna design because it provides the best resonance.

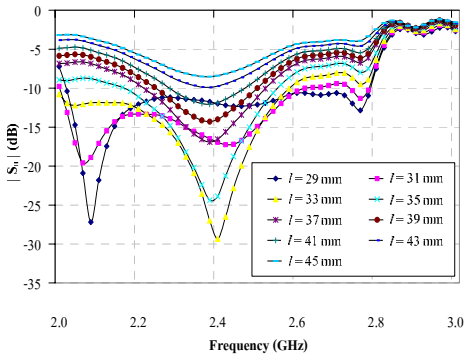

Fig.12 Frequency response of return loss as a function of probe length

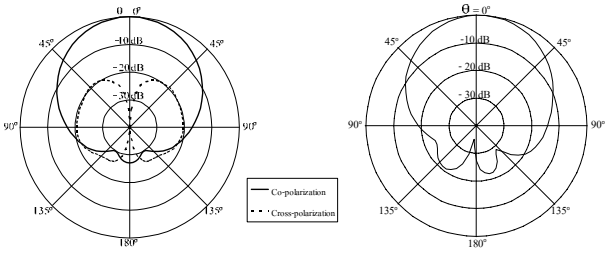
IV. SIMULATION RESULTS

A. Radiation Characteristics

From the previous section, the appropriate parameters were selected as inner ring radius (*a*) of 42.355 mm, inner ring length (*t*) of 17.765 mm, outer ring radius (*b*) of 58.295 mm, outer ring length (*d*) of 47.43 mm, distance from probe and reflector (*h*) of 32 mm, and probe length (*l)* of 33 mm. The proposed antenna provides the unidirectional pattern with the vertically linear polarization. The half-power beamwidth (HPBW) in both in E-plane and H-plane are 64.1^{o} and 64.8^{o}, respectively. The front-to-back ratio (F/B) in both planes is greater than 20 dB. Figure 13 shows the simulated radiation pattern in H-plane that it consists of co-polarization and cross-polarization and in E-plane the result shows only co-polarization because cross-polarization is less than co-polarization more than 40 dB. The maximum gain of the proposed antenna is 9.19 dBi at the frequency 2.45 GHz as can be seen in Fig.14.



(a) H-plane (XZ-plane) (b) E-plane (YZ-plane)

Fig.13 The radiation pattern

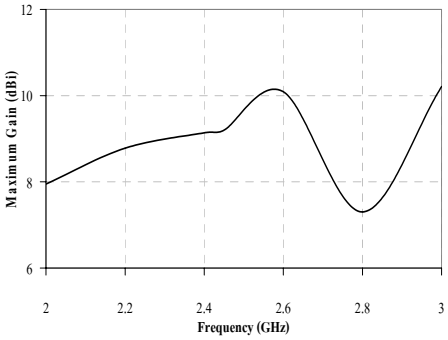


Fig.14 Frequency response of maximum gain

B. Impedance Characteristics

The impedance bandwidth (VSWR<2) of the proposed antenna is 28.30% and the resonant frequency is 2.45 GHz as shown in Fig. 15.

C. Polarization Characteristics

The simulated axial ratio of main lobe in H-plane is approximately 120 dB as shown in Fig.16. Therefore, this antenna radiates the dominantly vertically linear polarization.

V. DISCUSSIONS AND CONCLUSIONS

This paper describes a vertically polarized concentric circular ring antenna above the reflector with simple structure, low cost and high gain. The parametric study is also presented for finding the suitable parameters to meet the requirement of high gain. From the simulation results, it confirms that this antenna is suitable for applying in point-to-point communication of wireless Local Area Network (WLAN) system.

***Abstract*-Since durian has specific properties such as big peel, non-uniform shape, rough skin, etc. The non-destructive maturity determination is difficult to perform. This paper proposes microwave free-space measurement by using two microstrip patch antennas as transmitter and receiver operating in 2.4 GHz of frequency to determine the scattering parameters after passing through durian which can be calculated in term of complex permittivity. This method can save the costs that the results can be calculated from the amplitude of wave, no need the network analyzer. The results show that the technique can provide fast durian maturity determination with 72.22% accuracy.**

I. INTRODUCTION

Thailand can make a lot of export values from the agricultures. Durian is the one of the commercial fruits with highest export value. In fruit quality control, it is very important to know the maturity of durian before exporting. There are many methods to determine their qualities, both in destructive and non-destructive. In non-destructive way, it is very difficult to determine because durian has massive of its thickness peel, non-uniformity shape and roughness prickle. In the quality determination of fruit, Ketsa and Dangkanit [1] presented the relation between the maturity of durian and the chemical compound in the prickle of durian which destructive technique. Javier et al. [2] and Yang [3] presented the vision system for fruit determination with color, size and shape. Lee et al. [4] and Slaughter [5] presented near infared to determine chemical structure inside tomato and peach. However, the infared technique is not appropriate for pericarp fruit. T. Anupun et al. [6] presented the durian maturity determination by knocking and then took its signal to analyze for determination of frequency response. But the result showed low accuracy because of non-linearization of knocking. W. Kongratanaprasert et al. [7] presented non-destructive maturity determination of durian by force vibration and ultrasonic. T. Rutpralom et al. [8] presented non-destructive durian maturity determination by using microwave free-space measurement.

In this paper, we present the non-destructive technique of durian maturity determination by using microwave moisture sensing. This method using 2.45 GHz of microwave beam to measure the scattering parameters between the transmitter and the receiver. Then we calculate them in term of complex permittivity which is used to classify the property of a durian. Then the result is compared with percentage dry weight of durian after drying.

This method can save the costs because the results are calculated from the amplitude of the wave, do not need the network analyzer. The basic concept, experimental result and conclusion are showed in next chapter.

II. BASIC CONCEPT

A. Basic Microwave Material Interaction

When microwaves are directed towards a material, part of the energy is reflected, part is transmitted through the surface, and part of it is absorbed. The proportions of energy, which fall into these categories, have been defined in term of the dielectric properties. The fundamental electrical property though which the interactions are described is the complex relative permittivity of the material, ε^*. It is mathematically expressed as

$$\varepsilon^* = \varepsilon' - j\varepsilon'' \qquad (1)$$

where ε' = dielectric constant, and
ε'' = dielectric loss factor

The absolute permittivity of a vacuum, ε_0, is determined by

$$C_0 \mu_0 \varepsilon_0 = 1 \qquad (2)$$

where C_0 = speed of light in free space
μ_0 = magnetic constant = 1.26×10^{-6} H/m
ε_0 = 8.854×10^{-12} F/m

B. Free Space Method

This method use beams of electromagnetic radiation that pass through the dielectric sample as shown in Figure 1. The wave travels from the radiating antenna to the receiving antenna through the two media of air and sample.

The total reflection and transmission coefficients are given by

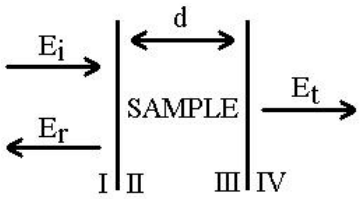

Fig1. Reflection/transmission measurement configuration

For lossy materials, the total reflection and transmission coefficients are given by

$$r = r_{12} = \frac{\sqrt{1} - \sqrt{\varepsilon_r}}{\sqrt{1} + \sqrt{\varepsilon_r}} \quad (3)$$

$$t = (1 - r_{12}^2)e^{-j\Theta} \quad (4)$$

where $\Theta = k_0 \sqrt{\varepsilon_r} d$, $k_0 = \frac{2\pi}{\lambda_0}$, (5)

Here, ε_r is the relative permittivity of the sample, and λ_0 is the wavelength in free space.

To find the permittivity by using any root-finding method, in (3) and (4) should be solved simultaneously. In order to simplify the solution of the equations, let $\sqrt{\varepsilon_r} = a - jb$. The expressions for reflection and transmission coefficients then become

$$r = r_{12} = \frac{1 - (a - jb)}{1 + (a - jb)} \quad , \quad t = \frac{4(a - jb)e^{-j\Theta}}{(1 + a - jb)^2} \quad (6)$$

and the amplitudes of reflection and transmission coefficients can written as

$$|r| = \frac{\sqrt{(1-a)^2 + b^2}}{\sqrt{(1+a)^2 + b^2}} \quad (7)$$

and

$$|t| = \frac{4\sqrt{a^2 + b^2}e^{-k_0 db}}{(1+a)^2 + b^2} \quad (8)$$

From (7) and (8), we get the final equation as

$$\sqrt{2a(1 - |r|^4) - (1 - |r|^2)^2} \cdot \exp\left\{-k_0 d \sqrt{\frac{2a(1 + |r|^2)}{(1 - |r|^2)} - (1 + a^2)}\right\} - |t| a = 0 \quad (9)$$

that depend on a .

The real and imaginary parts of the permittivity are then calculated by using the following simple equations

$$\varepsilon_r' = a^2 - b^2 \text{ and } \varepsilon_r'' = 2ab \quad (10)$$

The amplitudes of reflection and transmission coefficients together with the thickness of the sample uniquely determine the complex dielectric permittivity of cement-based specimens.

III. Experimental Setup

In the experiment, 2 microstrip patch antennas have been designed as shown in Fig.2, the dimension of the microstrip patch antenna is a = 90 mm, b = 90 mm, c = 5 mm.

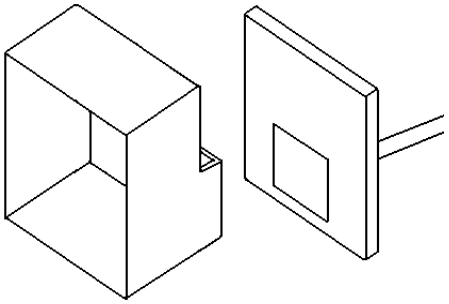

Fig 2. The designed microstrip patch antenna.

The measurement setup is shown in Fig.3 to determine the voltage that transmitted and reflected. Then change into transmission and reflection coefficient. Finally the data is calculated for permittivity by using Matlab software.

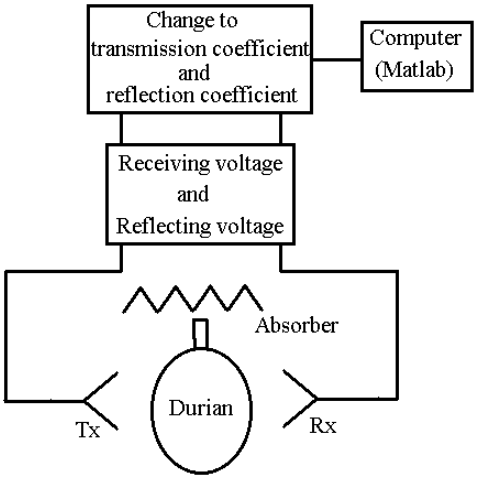

Fig 3. Measurement setup.

IV. Result

18 durians (Monthong) weight 4-4.5 kg. are sampled from Rayong market . The experiment for permittivity of durians determination is shown in Fig. 6, the transmitter and receiver antenna are placed in the same vertical level and close contact to durian surface to prevent non-direct signal path go to the

receiver antenna. The transmission and reflection coefficient is measured and calculated for real part of complex permittivity of durian.

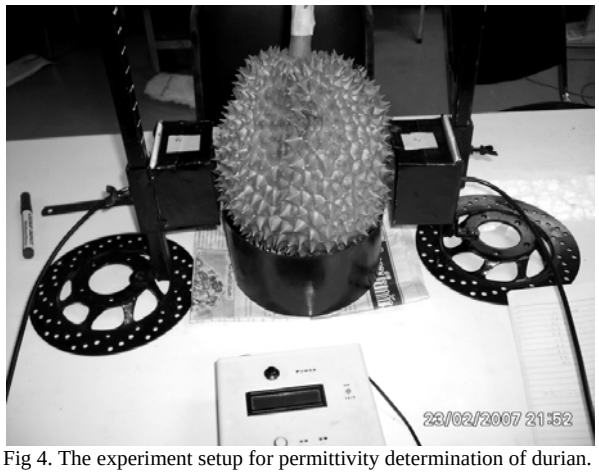

Fig 4. The experiment setup for permittivity determination of durian.

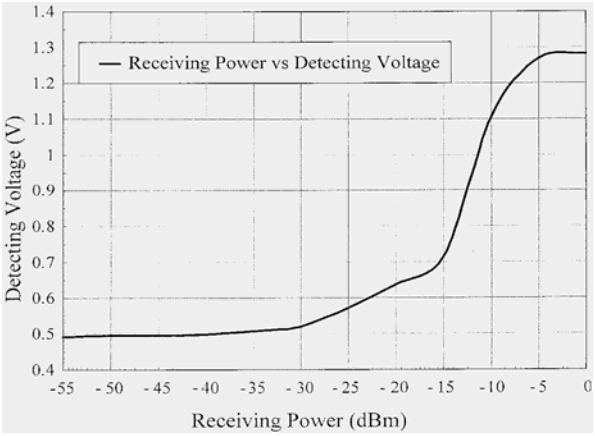
The voltage can change into the amplitude of the transmission and reflection coefficients by the following graphs.



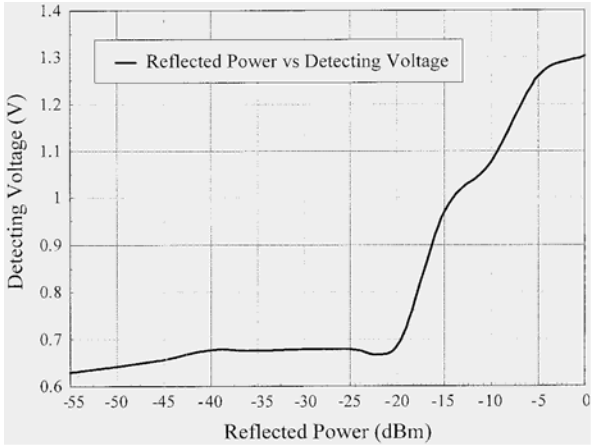


Fig 5. The amplitude transmission and reflection coefficients from measured voltages.

A. Dry-Weight Percentage Determination

The standard maturity classification of durian has been proposed by Peerapong [5] 50 g. of durian pulp is fumed 65 C° for 48 hours, Percentage dry-weight can be obtained from Equation (11).

$$\%Dry-weight = \frac{W_{after}}{W_{before}} 100\% \qquad (11)$$

Where W_{after} is weight after fuming
W_{before} is weight before fuming

From his result, he found that the % dry-weight threshold value is 30, the % dry-weight of immature durian is less than 30% and the % dry-weight of mature durian is more than 30% so in our experiment, we use this dry-weight percentage result as a standard maturity classification.

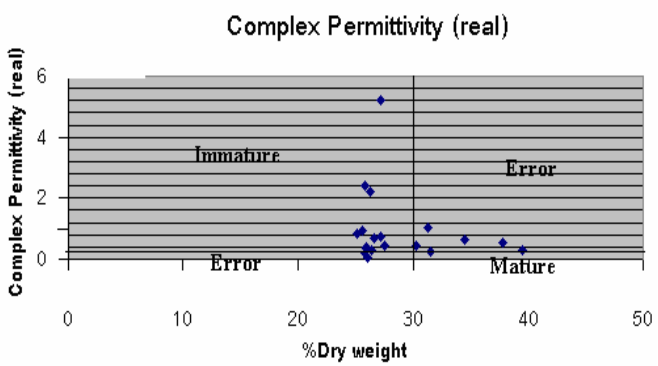

Fig 6. The result of 18 durian samples between real part of complex permittivity and %dry-weight.

From graph in Fig.6 above, it shows that the real part of complex permittivity is more than 0.4 and %dry-weight is less than 30% means durian is immature. Real part of complex permittivity is less than 0.4 and %dry-weight is more than 30% means durian is mature. In the left lower and right upper region of the graph are the error regions. The error occurs from non-uniform shape of durian causes incorrect sample length.

V. Conclusion

This paper presents nondestructive durian maturity determination by using microwave free space measurement. The complex permittivity of material such as agricultural products can be determined with fast and accurate. The results show that this technique gives 72.22**%** accuracy.

***Abstract*- The interdigital microstrip resonator sensor in two configurations for measurement of complex permittivity in compact areas of material under test is proposed. As a consequence, the characteristics of resonator including resonant frequency and bandwidth vary with dielectric constant and loss tangent of material. Limitations in the frequency response performance of the proposed sensors have been carefully studied. It has been found that the proposed sensors have great potentials for practical applications in view of low cost and monolithic integration capability with the driving circuit.**

I. INTRODUCTION

In numerous applications, a nondestructive monitorization of dielectric properties of materials is required. The electromagnetic radiation of the microwave region is widely used by microwave sensors. Microwave dielectric measurement methods generally fall into two categories: non-resonant and resonant methods. Non-resonant methods mainly include reflection and transmission/reflection techniques [1]–[3]. Resonant methods, mainly including resonator and resonant perturbation methods, have relatively higher accuracy than non-resonant ones [4]–[8]. In resonant methods, the sample under measurement is introduced to a resonator thus altering the electromagnetic boundaries of the resonator, and the electromagnetic properties of the sample are deduced from the change of the resonant properties of the resonator. Due to its high accuracy and its flexibility in sample preparation, the resonant method is widely used for low-loss samples, powders, small size samples and samples of irregular shapes. The sensors based on waveguide and coaxial lines are bulky and not convenient for integration with electronic circuits.

A planar transmission lines are used in order to develop a compact sensor to measure the permittivity [9]. Several investigators have used microstrip resonators for the determination of dielectric constant and dielectric loss of materials. The resonator structure is very simple, low cost, and easy to remove samples. The microwave sensors based on an interdigital microstrip resonator sensor for the complex permittivity materials have been developed. A software procedure has been also created that allows the direct identification of the complex permittivity as a function of the resonant frequency and the 3-dB bandwidth. The measurement system is shown in Fig.1, consisting of a sensor, a detector, a VCO and a processor unit.

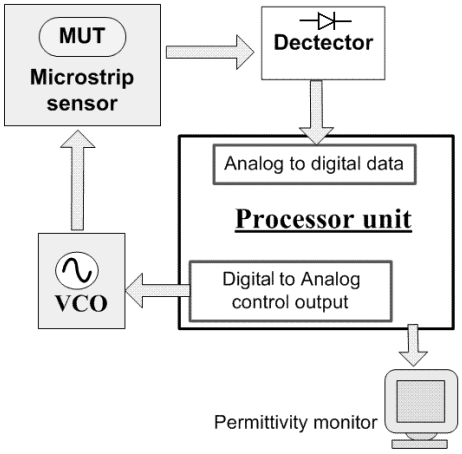

Fig. 1 Block diagram of the dielectric permittivity measurement system

Complex permittivity measurement can be performed by choosing the sensor that best fits to the user's specifications, thus adapting the measurement capability to the case of interest. Changes in permittivity manifest them selves as changes in resonant frequency of the microstrip sensor. A voltage controlled signal source and appropriate electronics are interfaced to the resonator under computer control. Different process can be used as sensor – a coaxial probe having a big size, can be used for large area samples and has a higher penetration depth, while the planar microstrip sensor is more suitable for small areas of the material under test (MUT).

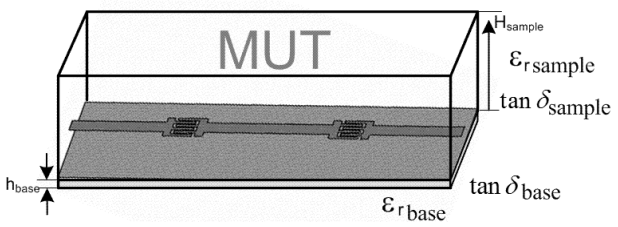

Fig. 2 3-D geometry of the proposed microstrip sensor

This paper proposes new microstrip resonant sensors to obtain high measurement performances with a wide range of dielectric constant including small size, low cost, and high sensitivity. The sensor allows monitoring the MUT properties by placing it above the strip (see an example of MUT location in Fig. 2) and performing continuous measurements at a fixed frequency of transmission characteristic. A 3-D geometry of the proposed microstrip sensor is shown in Fig. 2. The microstrip resonant sensor is on a dielectric layer, called the base substrate. It has known parameters including a thickness (h_{base}) and a complex relative permittivity (ε_{rbase}) and a loss tangent ($\tan\delta_{base}$). The MUT is a dielectric layer with unknown dielectric constant ($\varepsilon_{rsample}$) and loss tangent ($\tan\delta_{sample}$), called the sample layer. The thickness of this layer is also known. From [10], the results suggest that for the finite thickness greater than 10 mm as long as $\varepsilon_{rsample} \geq 2.1$, the MUT can be assumed as infinitely thick with good approximation. From Fig. 2, there are two layers, the base substrate and the sample layer with unknown relative permittivity and loss tangent; therefore it is posible to determine the relative permittivity and loss tangent of the material.

II. MICROSTRIP SENSOR TOPOLOGIES AND SIMULATION RESULTS

In this paper, two microstrip sensors with different operating of frequency ranges have been investigated and compared in terms of their dielectric constant ranges and performances. In Fig.3, the microstrip sensor structure is designed on interdigital microstrip resonator model which included Cg , Cp and a resonator. The model of a interdigital microstrip resonator was simulated using IE3D [11]. The MUT was also included in the simulation and the object parameters of the MUT including thickness, dielectric constant and loss tangent were varied for each simulation. The considered topologies are shown in Fig.4. Fig.4 (a) illustrates the layout of the microstrip sensor type A using interdigital microstrip resonator for a lower frequency bandwidth with a center frequency of 876 MHz for air-filled MUT or a dielectric constant of 1. In Fig.4 (b), the configuration type B contains the same structure with Fig.4 (a) but operates at a higher frequency band with a center frequency of 3.835 GHz. The resonators were constructed using interdigital microstrip resonators. The responses of microstrip sensors type A and type B for different values of permittivities of the MUT are shown in Fig.5 and 6, respectively.

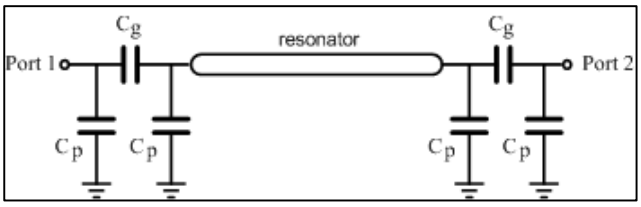

Fig. 3 The proposed microstrip sensor model [11]

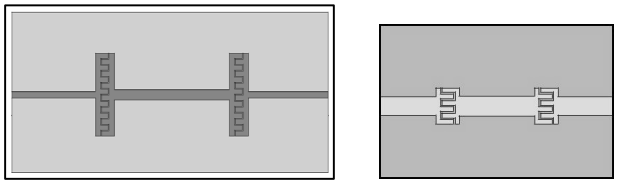

Fig.4 Interdigital microstrip resonators on FR4 substrate
(a) type A for low frequency band and size of 120*60mm
(b) type B for high frequency band and size of 37*24mm.

As a microstrip sensor typeA, a variation of the complex permittivity of the MUT causes a variation of the resonant frequency and 3-dB bandwidth which a dielectric constant are changing from 2.1 to 9. The result resonant frequency will be changing of 876-634 MHz. This can identify materials [12] by related approximate equation (1).

III. CHARACTERIZATION OF SENSORS

In this session, the characteristic responses of microstrip sensors are shown in Fig. 7 and Fig. 8. The complex permittivities in a wide range of sequence MUT are simulated by IE3D software which an effect output response has two parameters. These are resonant frequency response (Fig.7) and bandwidth response (Fig.8). In Fig.7, the output response of changed dielectric constant in X-axis is resonant frequency response in Y-axis. The resonant frequency point is related a loss tangent in many values which start from 0.0001 to 0.1. In resonant frequency response, the sensor type A is stable variability more than type B because a response after the dielectric constant of 12 in type B will be fluctuated. Therefore, the operative resonant frequency designed in this model should be careful at high frequency. The approximate equations (1) and (2) are used for dielectric constant calculation and equation (1) is used for sensor type A which is limited in range of dielectric constant not over of 24. In Fig.8, the output response of changed loss tangent in X-axis is

$$\varepsilon_r = 389.35e^{f_r/(-177.3)} - 1.99 \quad (1)$$

$$\varepsilon_r = 130.1e^{f_r/(-1.097)} - 2.729 \quad (2)$$

bandwidth response in Y-axis. The bandwidth response is determined for each value of dielectric constant. Subsequently, the bandwidth responses of sensors type A and type B are shown in Fig. 8. The trends of bandwidth response are linear responses but some responses are not. In Fig.8 (a), it can be seen that increasing of bandwidth response has a minimal change from loss tangent lower of 0.008. These minimal changes can not be classified into a loss tangent of MUT different response from Fig.8 (b). Fig.8 (b) is explicitly classified more than Fig.8 (a). Therefore, the high frequency sensor design can be identified MUT in loss tangent session , such as sensor type B which an approximate equations are becoming to be classified MUT and (3),(4),(5) equations are used to calculate loss tangent which their dielectric constants have been obtained in the following: 2.0,3.0,5.0. In other words, the effective bandwidth responses of microstrip -sensor type B at dielectric constant over of 13 are nonlinear. The approximate equations of sensor type A can be limitly used , which a loss tangent lower than 0.008 may result in error.

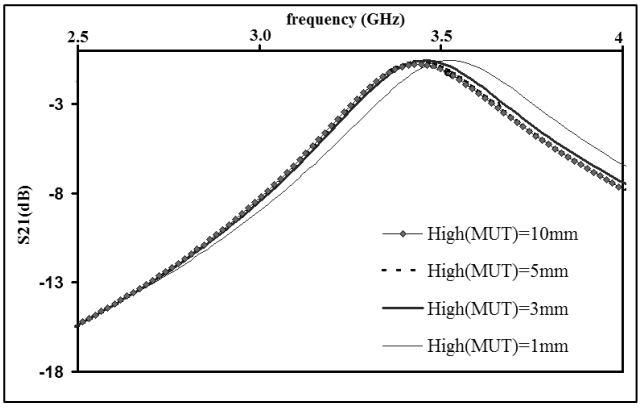

Fig. 10 Dependence of response on MUT thickness (h_{base})

$$\tan\delta = 0.001102BW - 0.53382 \quad ; \varepsilon_r = 2.0 \qquad (3)$$
$$\tan\delta = 0.000753BW - 0.39709 \quad ; \varepsilon_r = 3.0 \qquad (4)$$
$$\tan\delta = 0.000639BW - 0.36827 \quad ; \varepsilon_r = 5.0 \qquad (5)$$
$$\tan\delta = 0.001102BW - 0.53382 \quad ; \varepsilon_r = 2.0 \qquad (6)$$
$$\tan\delta = 0.003189BW - 0.18703 \quad ; \varepsilon_r = 22.0, 24.0 \qquad (7)$$

The MUT is represented by the dielectric layer. Its thickness (h_{base}) in Fig.2. Fig.10 shows the typical frequency response of the sensor for different thicknesses of the MUT. Since the effect of the finite thickness increases with decreasing h_{base}, the result of Fig.10 suggests that for height (MUT) greater than 5 mm, the MUT can be assumed as infinitely thick with good approximation.

V. CONCLUSION

For the purpose of determining of complex permittivities of dielectric materials, the resonator sensors have been proposed. Two resonator sensors based on interdigital microstrip resonators have been designed and analysed. The resonant frequency and bandwidth of the sensors have been simulated and investigated, resulting in formulation of permittivity equations for MUT with each sensor. These proposed sensors have very high performances with low cost and simplicity for manufacturing, therefore, they may be useful for permittivity characterization for a wide range of materials.

Abstract- In this paper, miniaturized dual-mode microstrips bandpass filter using the triangular loop structure is proposed by contain excellent performance. The proposed filter shows a 3.6% fractional bandwidth at the center frequency of 1.4 GHz with a return loss of better than 10 dB and an insertion loss of less than 2 dB. The size of the proposed structure is 50% less than conventional dual-mode microstrip triangular loop resonator filter at the same center frequency.

I. INTRODUCTION

Modern microwave communications systems such as satellite and mobile communications systems require compact size, high performance, and low-cost bandpass filters. Therefore, dual-mode microstrip filters have been widely used in wireless communications systems because of their advantages in applications requiring high-quality narrow-band microwave bandpass filters with features such as small size, low mass, and low loss.

Dual-mode microstrip resonators are attractive since a single dual-mode resonator can be utilized as a doubly tuned resonant circuit and, hence, the number of resonators required for a prescribed filter degree is reduced by half, resulting in a reduced-size filter structure [1]. Many authors [2]-[4] have proposed the dual-mode microstrip loop and patch resonators for miniaturization of the dual-mode microstrip filters. Recently, a dual-mode loop resonator using the properties of microstrip open-loop resonator has been proposed for miniaturization of the microstrip dual-mode filters [5].

A bandpass filter based on a dual-mode resonator can achieve Chebyshev, elliptic, or quasi-elliptic responses if the feed lines, notches, or stubs are properly arranged [6]-[10]. The strength and nature of the coupling between the degenerate modes of the dual-mode resonator are mainly determined by the perturbation's size and shape [6]. For instance, a bandpass filter based on a dual-mode microstrip square-patch resonator having a perturbation in the form of a corner cut can produce a Chebyshev characteristic [5], whereas one with a perturbation in the form of a small conductor patch attached to an outer corner of the same dual-mode resonator exhibits an elliptic characteristic. This is because the perturbation's shape on a patch resonator determines the nature of the coupling, whether it is inductive or capacitive. A perturbation in the form of a corner cut produces the inductive effect, while the capacitive effect is obtained by the perturbation in the form of a patch.

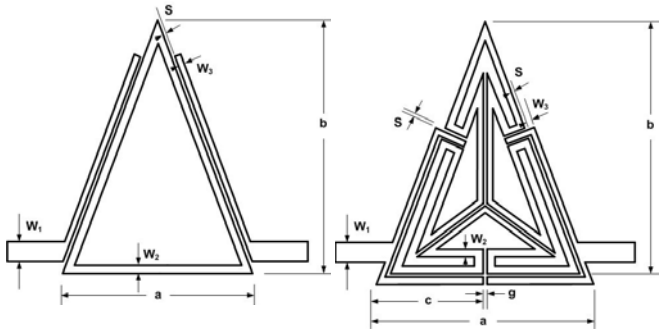

Fig. 1. *Configuration of the conventional dual-mode triangular loop structure (a) and the proposed miniaturized dual-mode triangular loop structure (b) the resonator dimensions are a = 20 mm, b = 27 mm, w_1 = 1.83 mm, w_2 = 1 mm, w_3 = 0.5 mm, c = 10.7 mm, s = 0.12 and g = 0.2 mm.*

A microstrip triangular loop resonator which reduces or eliminates some of the limitations of dual-mode bandpass filters based on microstrip loops. To allow easier coupling between the modes of two separate dual-mode resonators, we need the structure which is not symmetric with respect to two orthogonal planes. A simple structure which fulfills this requirement is a triangle although other solutions are possible. The triangular microstrip loop has several advantages, it has smaller size than a triangular patch as used in [1]. Differences in the resonant frequencies of the two modes can be easily adjusted be changing the height of the triangle. There is no need to couple the two modes of a given dual-mode resonator by inserting a perturbation. Filters with transmission zeros both at real frequency (attenuation poles) and at imaginary frequencies (group-delay flattening) can be designed with the same arrangement [11].

In this paper, we have proposed a miniaturized dual-mode microstrip filter using the degenerate mode of a modified triangular loop structure, which has a size reduction of more than 50% at the same center frequency compared with the conventional triangular loop structure [11].

II. DUAL – MODE RESONATOR

Single-mode microstrip resonator, such as broad side edge coupled filters, have been long established. However, single-mode filters have limited applications in microwave areas due to their low performance in terms of insertion loss and narrow bandwidth in pass-band regions. Hence, to improve the filter performance, the dual-mode microstrip resonating filters are more commonly adopted. The basic idea is to constructively couple two resonating modes, TM^{z100} and TM^{z010}, inside a resonator for a better performance. Planar dual-mode filters were first introduced in [12].

The triangle loop dual-mode resonator is simply a wavelength long microstrip line whose two ends are joined to form a triangle. Two of the sides of the triangle are always maintained equal, i.e., the triangle is isosceles. The structure is therefore, symmetric with respect to a plane going orthogonally through the middle of its bottom edge. Two degenerate modes can exist in such a structure, one with a magnetic wall (mode 1) and the other with an electric wall (mode 2) along the symmetry plane [11].

The proposed dual-mode resonator has been shown in Fig. 1(b). It consists of three identical arms, each of which may be viewed as a line with a triangular ring stub. The triangular ring stub increases the resonator perimeter significantly and hence decreases the resonance frequency. The proposed structure uses the space inside the loop efficiently when compared with the conventional triangular loop resonator shown in Fig. 1(a).

The resonance frequency of the both structures has been compared. Fig. 2 shows that the resonance frequency of the proposed resonator is much smaller than the conventional dual-mode triangular loop resonator for the same dimensions. The simulated results are given in Fig. 2. The resonant responses are obtained from both structures with the same size. It can be noticed that the proposed structure has a resonant frequency of 1.4 GHz, compared to 2.8 GHz of the conventional triangular loop structure. This means the proposed structure can be made smaller than the conventional structure when they resonate at the same frequency.

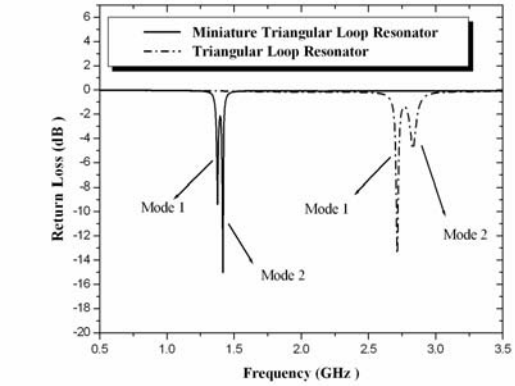

Fig. 2. Simulated return loss for the dual-mode triangular loop structure (broken line) and proposed miniaturized dual-mode triangular loop structure (full line).

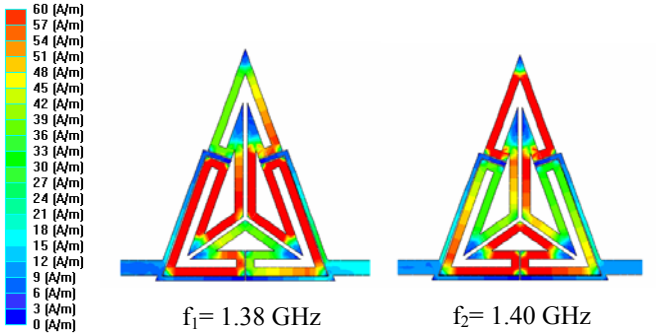

Fig. 3. Simulated current distribution for two resonance frequency of degenerated modes. (a) Mode 1 (magnetic wall along two side of the triangle). (b) Mode 2 (electric wall along two side of the triangle).

The simulated current distribution of the two modes can be easily computed from a full-wave simulation. In this study, the commercial software package, IE3D, is used for this purpose as well as for the analysis and the design of the resonator. By inspecting the current distribution patterns in Fig. 3, we can see that mode 1 is actually an even mode, while mode 2 is an odd mode. The current distribution of mode 1 is shown in Fig. 3(a). It can be seen that a high concentration is at the top tip and the center of the bottom edge of the triangle which called the electric wall. Fig. 3(b) shows the current distribution on the microstrip loop for mode 2. The field is mostly concentrated on the two lateral sides of the triangle which called the electric wall.

To observe the mode splitting, the dual-mode loop resonator has been simulated with different relative values of the length (a) and the height (b) of the base. The simulated split resonance frequencies of these degenerate modes of the triangular loop resonator as a function of are shown in Fig. 4. The split between the mode frequencies decreases as the height of the triangle increases from 15 mm up to 35 mm.

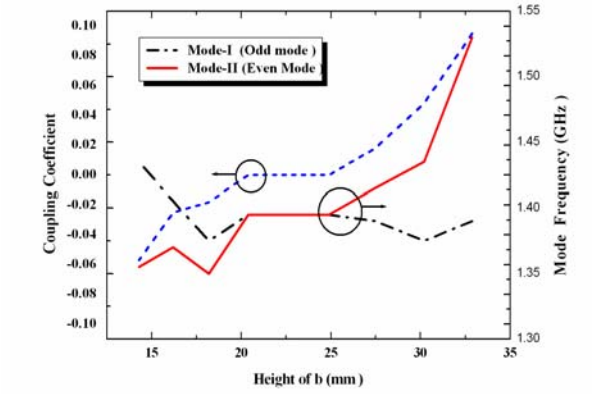

Fig. 4. Simulated coupling coefficient and two resonance frequencies of degenerate mode against the height of triangle.

This situation can also be seen from the coupling coefficient computed using the relationship between the split in the resonance frequency of two modes and the coupling, as described by [15]

$$k = \frac{f_{02}^2 - f_{01}^2}{f_{02}^2 + f_{01}^2} \tag{7}$$

where f_{01} and f_{02} are resonance frequency of mode 1 and mode 2, respectively. The coupling coefficient between the resonant frequency of mode 1 and mode 2 is also shown in Fig. 4.

Since we need to split mode of equilateral triangular loop resonator for design a bandpass filter, the mode splitting is achieved by changing height of the isosceles triangle, where $b < \sqrt{3}a/2$. We found that the resonant frequency of mode 1 was exited at lower than mode 2. The coupling coefficient becomes negative coupling coefficient (or electric coupling). Where $b > \sqrt{3}a/2$, it is found that the resonant frequency of mode 1 was exited at higher than mode 2, the coupling coefficient becomes positive coupling coefficient (or magnetic coupling). When $b = \sqrt{3}a/2$, the coupling coefficient becomes zero since the dual-mode resonator is a simple microstrip loop resonator.

III. Dual – Mode Filter

The equivalent circuits of the dual-mode triangular loop filter for even and odd modes. The impedance of the two networks at the feed point can be derived as follows [13] shown in Fig. 5.

$$Z_{even} = jZ_x\left(\frac{y_s \tan\theta_2 - 1}{y_s(1 - \tan\theta_1 \tan\theta_2) + \tan\theta_1 + \tan\theta_2} - \frac{1}{y_g}\right) \tag{1}$$

$$Z_{odd} = jZ_x\left(\frac{1}{(\cot\theta_1 + \cot\theta_2)} - \frac{1}{y_g}\right) \tag{2}$$

where Z_0 is the terminated impedance, Z_{even} and Z_{odd} are the input impedances of the half-circuits corresponding to the even and odd modes about the symmetric line, respectively. $\theta_1 = \beta l_1$, $l_1 = \sqrt{a^2 + b^2}$, $\theta_2 = \beta l_2$, $l_2 = a/2$, $y_g = 2\pi f c_g Z_x$, and $y_s = 2\pi f c_s Z_x$, C_g and C_s are the equivalent capacitances of the coupling gap and top tip of triangle, respectively. For design, the center frequency and Z_x are usually the prespecified parameters, where w_2, C_g, and C_s are the circuit variables to be lossless. The S -parameters of transmission and reflection for the triangle circuit are given by [14]

$$S_{11} = (\Gamma_{even} + \Gamma_{odd})/2 \tag{3}$$

$$S_{21} = (\Gamma_{even} - \Gamma_{odd})/2 \tag{4}$$

where

$$\Gamma_{even} = \frac{Z_{even} - Z_o}{Z_{even} + Z_o} \tag{5}$$

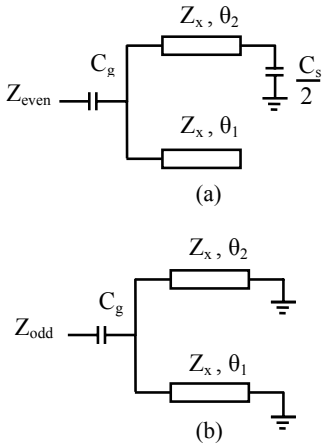

Fig. 5. *Equivalent circuits of the triangular loop dual-mode filter: (a) even mode; (b) odd mode.*

$$\Gamma_{odd} = \frac{Z_{odd} - Z_o}{Z_{odd} + Z_o} \tag{6}$$

Finally, the frequencies f_{z1}, f_{z2}, at which the transmission zeros are located, can be obtained by solving by setting insertion loss S_{21}=0.

The proposed dual–mode microstrip bandpass filter was fabricated on a GML-1000 substrate having a thickness of 0.762 mm and relative dielectric constant of 3.2. The filter dimensions are a = 20 mm, b = 27 mm, w_1 = 1.83 mm, w_2 = 1 mm, w_3 = 0.5 mm, c = 10.7 mm, s = 0.12 and g = 0.2 mm. Fig. 6 shows the photograph of the fabricated filter. The simulated bandwidth is about 3.6%, while the measured bandwidth is 5.7% at the center frequency of 1.4 GHz.

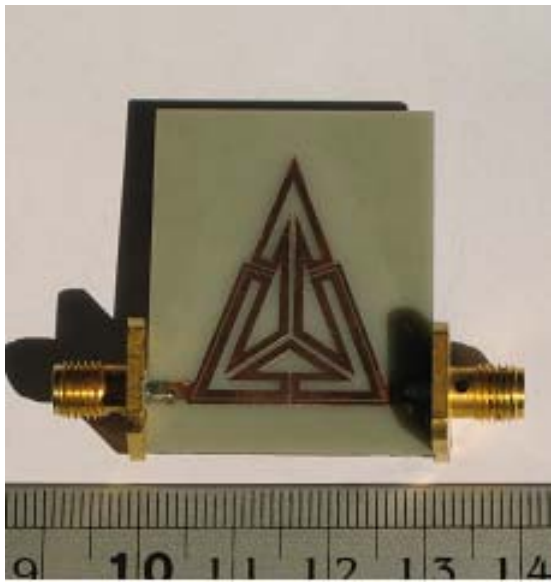

Fig. 6. *A fabricated of proposed dual-mode microstrip filter.*

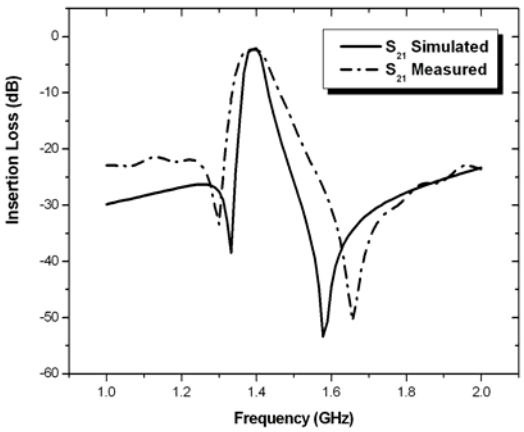

Fig. 7*. Simulated and measured responses (S_{21}) of the proposed filter.*

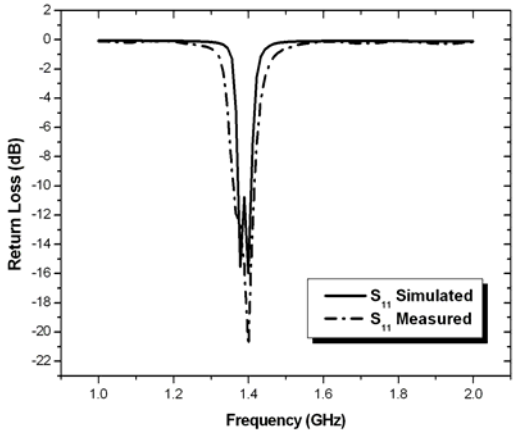

Fig. 8. *Simulated and measured responses (S_{11}) of the proposed filter.*

Fig. 7 shows the simulated and measured frequency responses, the measured insertion loss of filter is 2.3 dB, higher than the simulated value of 2 dB. The loss is due to circuit loss including conductor and dielectric losses. The return loss is better than 10 dB within passband as shown in Fig. 8. The simulated and measured results are in good agreement.

IV. CONCLUSION

A dual-mode band-pass filter with a 3.6% bandwidth at the center frequency of 1.4 GHz has been designed and fabricated to demonstrate the application of the proposed triangular loop resonator for designing the compact microstrip filters. Also, it has a size reduction of about 50% with respect to conventional triangular loop structure. The proposed filter responses have been measured resulting in good agreement with simulation expectations. The magnetic and electric coupling between degenerate mode of the dual-mode the proposed triangular loop resonator was identified depending on the height of triangle.

***Abstract*- Satellite communication with land mobile terminals in VHF and UHF bands is affected by ionospheric scintillation and multipath fading that causes strong variation in received signal power. In this paper, the performance of MPSK modulation in combined flat scintillation and frequency selective multipath fading channel with various fading conditions is presented. It is shown that for frequency-selective channels, Viterbi detector reduces the error floor, thus providing reduction of average bit error rate.**

I. INTRODUCTION

Satellite mobile communication in UHF band and lower frequency bands has been recently planned [1]. Combined scintillation and multipath fading channels are common in mobile satellite communication and have become impediments to reliable transmission system.

Scintillation effects are caused by non-uniform electrical charge distribution in the ionosphere layer. The phenomenon is maximum near the geomagnetic equator and smallest in the mid-latitude regions [1]. It is statistically modeled as Rician or Rayleigh fading with finite signal decorrelation time and limited coherent bandwidth of the transmission channel [2]. If the modulated signal is transmitted through the ionosphere with electrical charge fluctuation, there would be an effect on signal amplitude, the signal level swings rapidly up and down from normal level. The frequency-selective multipath fading channel is characterized by rural area power delay profiles defined in COST207 models [3].

The fading can be "flat"or "frequency selective" depending upon delay spread in communication medium and symbol rate, when the delays are short compared to the symbol rate, the medium is flat fading channel. Conversely, when the delays are long compared to the symbol rate, the channel is considered frequency-selective fading channel.

Previously in [4], the performance of MPSK modulation in combined scintillation and flat multipath fading system is analyzed.

In this paper, we simulate the performance of combined channels for mobile satellite communication with MPSK, specifically, QPSK modulation scheme. The performance is shown in terms of bit error rate versus signal-to-noise ratio (SNR) and the plots are then illustrated.

The paper is organized as follows. In Section II, system model and basic definitions are reviewed. Section III describes the channel model. In Section IV, simulation results and discussions for scintillation channel, combined scintillation and frequency selective multipath fading channel. Finally, the conclusions are given in Section V.

II. SYSTEM MODEL AND BASIC DEFINITION

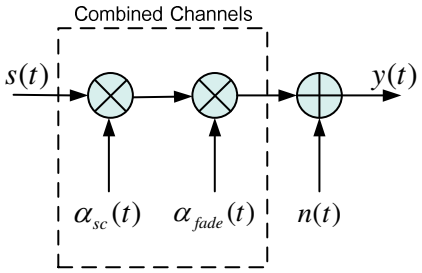

Fig. 1. Combined scintillation and multipath fading channel model

In combined scintillation-multipath channel given in Fig. 1, the received signal $y(t)$ is

$$y(t)=\sum_{n=-\infty}^{\infty}\alpha_{sc}(t)\cdot\alpha_{fade}(t)\cdot s(t-nT_s)+n(t) \qquad (1)$$

where $\alpha_{sc}(t)$ and $\alpha_{fade}(t)$ are scintillation and multipath fading coefficients, respectively, $s(t)$ is the modulated MPSK signal and $n(t)$ is an additive white Gaussian noise (AWGN) with zero mean and variance $\sigma^2 = N_0/2$ W/Hz.

In M-ary phase shift keying (MPSK) modulation is a common modulation scheme employed in satellite and wireless channel due to spectral efficiency. Each k-bit information sequence is mapped to a waveform of equal amplitude and M possible phases. The signal $s_i(t)$ can be expressed as

$$s_i(t)=\sqrt{\frac{2E}{T}}\cos\left(\omega_0 t-\frac{2\pi i}{M}\right);\quad \begin{matrix}0\le t\le T_s\\ i=1,...,M\end{matrix}, \qquad (2)$$

where E is the symbol energy over each the duration T_s and ω_0 is the radian frequency of the carrier. For an AWGN channel assuming coherent detection, the probability of bit error at high SNR can be expressed in terms of digital SNR $\left(E_b/N_0\right)$.

$$P_B \approx \frac{2Q\left(\sqrt{\frac{2E_b \cdot \log_2 M}{N_0}} \sin\frac{\pi}{M}\right)}{\log_2 M} \quad (3)$$

where $Q(x)$ is a Q-function, E_b is average bit energy and N_0 is the noise power spectral density.

III. CHANNEL MODEL

A. *Scintillation model*

Scintillation effects are caused by non-uniform electrical charge distributions in the ionosphere which depends on the ionosphere condition, location, season, solar activity and local time. Ionospheric scintillation is maximum near the geomagnetic equator and smallest in the mid-latitude regions. The received signal from scintillation effect causes amplitude signal fluctuations [1].

The intensity of scintillation is often measured by the scintillation index S4 which S4 can be found from standard deviation value to mean value of the received signal envelope.

In general, scintillation index has values $0 \le S4 \le 1$. When S4 = 0 is ideal non-fading channel, with $0 < S4 < 1$, it is Rician fading channel, and with S4 = 1, it is Rayleigh fading channel [6].

The scintillation coefficient $\alpha_{sc}(t)$ is statistically modeled as a non-zero mean, complex Gaussian random process [2].

$$\alpha_{sc}(t) = \sqrt{K_s} \cdot e^{j\phi} + n_{\text{scint}}(t), \quad (4)$$

where K_s is proportional to the signal power received via the line of sight path, ϕ is a random phase shift uniformly distributed over the interval $[-\pi, \pi]$ and $n_{\text{scint}}(t)$ is a complex Gaussian process that arises from scattered signal propagation over random paths due to atmospheric scintillation effects. The average signal power received over the scattered paths is proportional to $\sigma_{nsc}^2 = E\left|n_{sc\,\text{int}}(t)\right|^2$. Envelope signal power of scintillation coefficient $r_{sc} = \left|\alpha_{sc}(t)\right|$ has a Rician probability density given by:

$$P_{rsc}(r) = \frac{2r}{\sigma_{nsc}^2} \cdot e^{-\gamma} \cdot e^{-r^2/\sigma_{nsc}^2} \cdot I_0\left\{2r\sqrt{\gamma/\sigma_{nsc}^2}\right\} \quad (5)$$

where $\gamma \equiv K_s / \sigma_{nsc}^2$ is the ratio of received specular to scattered signal power and γ can be related to the scintillation index S_4 [6], then can be expressed as

$$S_4 = \sqrt{1 - \left\{\gamma/(\gamma+1)\right\}^2}. \quad (6)$$

The coefficient $\alpha_{sc}(t)$ can be generated in the time or frequency domain with the basic idea is to filter an independent complex Gaussian sequence to generate the scattered component $n_{\text{scint}}(t)$ and then combine the result with the specular component to produce $\alpha_{sc}(t)$. The magnitude-squared filter frequency response $\left|H_{sc}(f)\right|^2$ is matched to the power spectrum of $n_{\text{scint}}(t)$, *i.e.*,

$$\left|H_{sc}(f)\right|^2 = P_{sc}(f) = \int_{-\infty}^{\infty} d\tau \cdot R_{sc}(\tau) \cdot e^{-2\pi j f \tau} \quad (7)$$

The process is shown in Fig. 2, the filter frequency response is designed to have linear phase with $phase\left\{H_{sc}(f)\right\} = 2\pi\Delta f$, where Δ is typically set to half the duration of the filter impulse response.

$$h_{sc} = \int_{-\infty}^{\infty} df \cdot H_{sc}(f) \cdot e^{2\pi j f \tau} \quad (8)$$

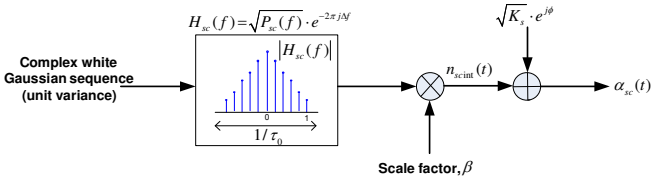

Fig. 2. Scintillation coefficient simulation model

For the discrete frequency response $\bar{H}_{sc}(k)$ of the discrete-time filter $\hat{h}_{sc}$ is computed from (8) as follows:

$$\bar{H}_{sc}(k) = \mathrm{e}^{-(\pi\tau_0 k F_s/N)^2/2} \cdot \mathrm{e}^{-(2\pi j(L/2)k/N)} \quad (9)$$

where $0 \le k \le N/2$ F_s is a sampling rate that is two to three times the maximum bandwidth of the square–root Gaussian filter and $N \ge L$ is the number of points computed. Finally, $\hat{h}_{sc}(k)$ is computed via inverse discrete Fourier transform.

$$\hat{h}_{sc}(k) = \frac{1}{N} \cdot w(k) \cdot \sum_{l=0}^{N-1} \hat{H}_{sc}(l) \cdot \exp\left(2\pi jkl/N\right) \quad (10)$$

where $0 \le k \le L-1$, $w(k)$ is a window function, L sampled in extent. Normally a Hamming window is used.

Given $\hat{h}_{sc}(k)$, the sampled scattered component $n_{sc\,\text{int}}(k/F_s)$ can generated via discrete convolution with a white, unit variance complex Gaussian input sequence $\xi(k)$ as follows:

$$n_{sc\,\text{int}}(k/F_s) = \beta \cdot \sum_{l=0}^{L-1} \hat{h}_{sc}(l) \cdot \xi(k-l), \quad (11)$$

where the scaling constant β is chosen to yield the desired output variance.

$$\beta = \sqrt{\sigma_{nsc}^2 / \sum_{l=0}^{L-1} \hat{h}_{sc}^2(l)} \quad (12)$$

As noted above, the value σ_{nsc}^2 is typically computed in terms of the desired Rician factor via $\sigma_{nsc}^2 = 1/(1+\gamma)$.

B. *Frequency-selective fading model*

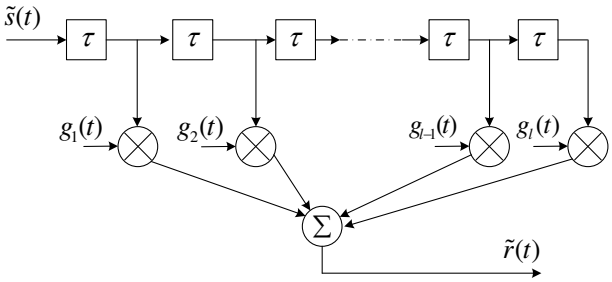

Fig. 3. Frequency-selective multipath fading channel model.

The complex envelope of the received signal $r(t)$ is

$$\tilde{r}(t)=\sum_{i=1}^{l} g_i(t)\cdot\tilde{s}(t-\tau_i) \tag{13}$$

where $\tilde{s}(t)$ is the complex envelop of the transmitted signal, l is the number of taps, $g_i(t)$ is the complex gains [3] and τ_i is path delays associated with the taps.

Multipath fading effects occur as the satellite signal is not only received via the direct path but also reflected from objects in the surrounding area. Each area contains different conditions which cause varying degrees of additions and subtractions of signal. In process of simulation, the frequency selective multipath fading channel is characterized by typical rural area (non-hilly) power delay profiles defined in COST207 models [3]. The COST207 models are useful for simulating GSM and other systems (up to 2 GHz band); the model describes the channel impulse response in terms of a set of Doppler characteristics at various specified time delays.

The power and delay profiles of the simple 6 path form for rural area are given in Table 1.

TABLE I
TYPICAL RURAL AREA POWER DELAY PROFILE DEFINED BY COST207 [2]

Delay (μs)	Fractional Power	Doppler Category
0.0	0.602	RICE
0.1	0.241	CLASS
0.2	0.096	CLASS
0.3	0.036	CLASS
0.4	0.018	CLASS
0.5	0.006	CLASS

In a tapped delay model, each channel has a Doppler spectrum $P_s(f,\tau_i)$, where i is the index of the tap. The following two types of Doppler spectra are defined in the COST 207 model, where $f_{\max}$ represents the maximum Doppler frequency of the channel.

- CLASS is the classical (Jakes) Doppler spectrum and is used for paths with delays not in excess of 500 ns $(\tau_i \le 0.5\mu s)$

$$P_s(f,\tau_i)=\frac{A}{\sqrt{1-\left(f/f_{\max}\right)^2}} \tag{14}$$

- RICE is the sum of a classical Doppler spectrum and one direct path. This spectrum is used for the shortest path of the model for propagation in rural areas.

$$P_s(f,\tau_i)=\frac{0.41}{2\pi f_{\max}\sqrt{1-\left(f/f_{\max}\right)^2}}+0.91\delta(f-0.7f_{\max}) \tag{15}$$

where $|f|\le f_{\max}$ and A is a normalization constant chosen so that $\int P_s(f,\tau_i)\,df=1$.

IV. SIMULATION RESULTS AND DISCUSSIONS

The performance of QPSK modulation in combined channels is simulated in this section. The channel is the product channel of flat scintillation and frequency selective multipath fading. The performance is in terms of bit error rate and the signal-to-noise (SNR) ratio is defined by E_b/N_0, where E_b is average bit energy and N_0 is the noise power spectral density in Watts/Hz.

In the simulation, QPSK modulation is selected with scintillation index S4 = 0 (no scintillation), 0.3, 0.6 and 0.9 respectively. The frequency selective multipath fading channel has 6 channel taps with delay profile [0, 0.1, 0.2, 0.3, 0.4, 0.5] μs and fractional power profile [0.602, 0.241, 0.096, 0.036, 0.018, 0.006]. Carrier frequency in the satellite mobile system is set to be 320 MHz and users' speed is 10 km/hours. The block size is 2048 bits with bit rate of 10 Mbps and noise in the system is AWGN.

In Fig. 4, we illustrate BER performance of QPSK modulation in flat scintillation channel as the scintillation index varies. It is evident that as the scintillation intensity level increases, the BER performance degrades. e.g., BER = $1\text{x}10^{-5}$, with S4 = 0.9, there is an SNR loss of 33 dB compared with the case of AWGN channel (S4 = 0).

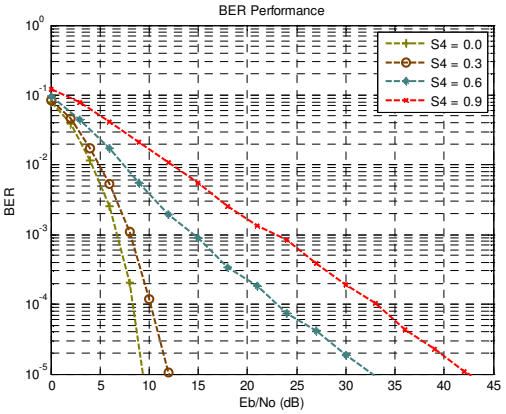

Fig. 4. BER performance of QPSK modulation in flat scintillation fading channel for S_4 = 0, 0.3, 0.6 and 0.9.

In Fig. 5, we illustrate the case of combined flat scintillation and frequency selective multipath fading channel with COST207 channel model. As scintillation index increases, the system performance in terms of bit error rate degrades. At low values of S4, the SNR loss is incrementally less than at high values of S4.

In addition, like any other fading channels, there exist irreducible error floors as the SNR increases, the error floors are caused by the delay spread. Compared with scintillation channels alone and channels in [4], the frequency-selective multipath fading causes more severe performance. Thus, to reduce the floors, the Viterbi detection is implemented to correct the intersymbol interference; the results are reduction of bit error rate and absence of error floors as shown in Fig. 6.

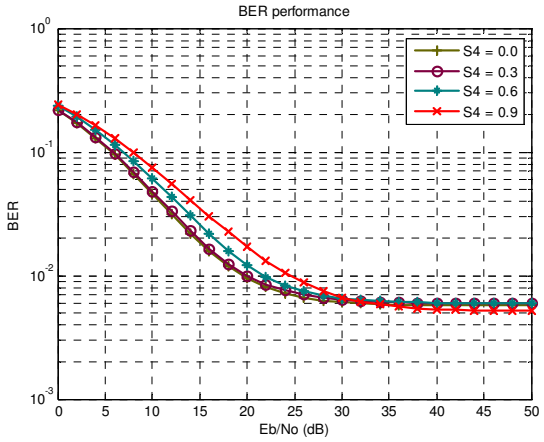

Fig. 5. BER performance of QPSK modulation in combined flat scintillation and frequency selective fading channel.

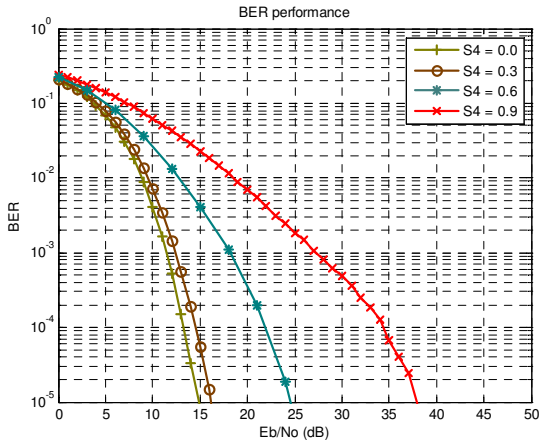

Fig. 6. BER performance of QPSK modulation in combined flat scintillation and frequency selective fading channel with Viterbi detector.

V. CONCLUSIONS

In this paper, we have simulated the performance of QPSK modulation in combined flat scintillation and frequency selective multipath fading channel. The system performance degrades as the scintillation intensity level increases and when combined with terrestrial frequency selective multipath fading, the bit error rate has additional loss and there are error floors occurring at high SNR. The error floors caused by the delay spread of the channel which can reduce the floors with the use of equalizers such as Viterbi detector.

ACKNOWLEDGMENT

I would like to acknowledge Prof. Nipa Leelaruji and Prof. Narong Hemakorn for providing suggestion and supportive facility at Satellite Communication Lab (SCL), ReCCIT, KMITL. In addition, I am grateful to student members of the lab for advice and proofreading assistance.

***Abstract*–This paper addresses an interference cancellation of orthogonal frequency division multiplexing (OFDM) system for aeronautical channel in the future. In this system, each sub-carrier contains all symbols transmitted in a given frame. Each symbol in the sub-carrier will be separated by orthogonal Hadamard sequences. The proposed method used with the multiple receiver antennas, called "minimum mean square error–diversity combiner (MMSE-DC)". The E_b/N_0 performance of the proposed system are improved. Simulation results shown the proposed system is better performance than MMSE-DC for 3dB at the BER of 10^{-4}.**

I. INTRODUCTION

Orthogonal frequency division multiplexing (OFDM) system is commonly used for high-data-rate applications in fading channels and has been chosen for several new standards such as digital audio broadcasting and wireless LAN [1], [2]. At the present, the number of fight is growth in regional and global air travel. Thus the channel bandwidth will be occupied. Since the OFDM system consists of a high-bit-rate and high spectral effiency [3], this element would be the most reasonable for solve to increase the demand of fight traffic and increase number of channel per system in the future. For the airport, the aeronautical channel scenarios consist of several conditions such as en-route scenarios, arrival and takeoff scenario, taxi scenarios, parking scenarios, aircraft flying over ground station. The interference of these communications will decrease the performance of OFDM system. In this paper, an interference cancellation of OFDM system for aeronautical channel is presented. The taxi and parking scenarios are considered.

II. SYSTEM MODEL

A. Transmitter system

The OFDM transmitter with interference cancellation for aeronautical communication is shown in Fig. 1. The input data stream rate R (bits/sec) though a serial-to-parallel converter which provides N parallel data streams, the data rate be R/N bits/sec. The output of parallel data that have the time interval is N time of original data. Let x_q is number parallel data q, spread by orthogonal Hadamard sequence [4] $w_q=[w_{q,0},w_{q,1},..,w_{q,N-1}]$, for q=0,1,…, N-1. After the spreading, the data rate is recovered to R bits/sec. x_q denotes QPSK modulated signal in complex form, i.e., $x_q=\alpha_q+j\beta_q$, the spread signal can be expressed as

$$X_{q,k} = x_q w_{q,k} = \alpha_q w_{q,k} + j\beta_q w_{q,k} \tag{1}$$

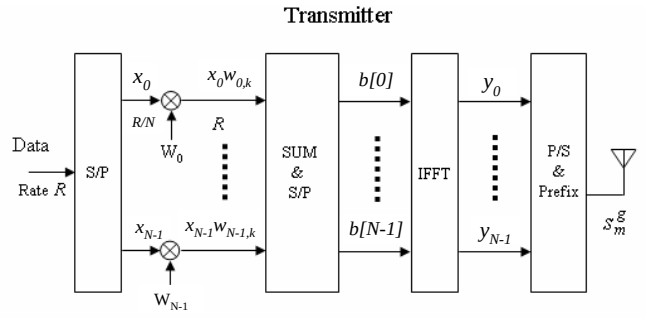

Fig. 1. Block diagram of OFDM transmitter system.

when k=0,1,…,N-1. The process is called orthogonal code division multiplexing (OCDM). After that, each spread signal is summed and a second serial to parallel converter, given as

$$b[k] = \sum_{q=0}^{N-1} x_q w_{q,k} \tag{2}$$

The signal b[k] is parallel signal. It applied to the input of inverse fast Fourier transform (IFFT) for convert frequency domain to time domain, express as

$$y_m = \sum_{k=0}^{N-1} b[k] e^{j2\pi\left(\frac{km}{N}\right)}; m = 0,1,\ldots,N-1 \tag{3}$$

Then, the output N parallel streams of IFFT can be added the guard time of each frame, called a cyclic prefix, to prevent the multipath fading channel. The cyclic prefix is actually a copy of the last portion of the data symbol appended to the front of the symbol during the guard interval. Then all symbols of each frame is $N_S=N+N_g$, for N_g is the number of guard-samples that added to the frame. The equation can be given by

$$s_m^g = \sum_{k=0}^{N-1} b[k] e^{j2\pi\left(\frac{km}{N}\right)}; m = -N_g,\ldots,N-1 \tag{4}$$

From the above detail, the N incoming data symbols consist of $[x_0,x_1,\ldots,x_{N-1}]$. This data symbols are applied to the input of OFDM transmitter and can express in matrix D_N follows as

$$D_{\tilde{N}} = \begin{bmatrix} x_0 & x_0 & \cdots & x_0 \\ x_1 & x_1 & \cdots & x_1 \\ \vdots & \vdots & \vdots & \vdots \\ x_{N-1} & x_{N-1} & \cdots & x_{N-1} \end{bmatrix} \begin{matrix} \leftarrow W_0 \\ \leftarrow W_1 \\ \vdots \\ \leftarrow W_{N-1} \end{matrix}$$
$$\begin{matrix} \uparrow & \uparrow & \cdots & \uparrow \\ f_0 & f_1 & \cdots & f_{N-1} \end{matrix}$$

It can be observed that the proposed method is every transmitter sub-carriers f_k contain all data symbols, x_0, x_1,…x_{N-1}, which each symbol is separated from each other by orthogonal Hadamard sequence. When compared with the ordinary OFDM, one sub-carrier spread to only one sub-carrier and w_q are not Hadamard sequence. Consider $W_q=[w_{q,k}]$, it will equal 1, when q=k and will equal 0 when q≠k, hence it can see that the ordinary OFDM system is a special case of proposed OFDM system, expressed in matrix D_N follows as

$$D_N = \begin{bmatrix} x_0 & 0 & \cdots & 0 \\ 0 & x_1 & \cdots & 0 \\ \vdots & \vdots & \vdots & \vdots \\ 0 & 0 & \cdots & x_{N-1} \end{bmatrix} \begin{matrix} \leftarrow W_0 \\ \leftarrow W_1 \\ \vdots \\ \leftarrow W_{N-1} \end{matrix}$$
$$\begin{matrix} \uparrow & \uparrow & \cdots & \uparrow \\ f_0 & f_1 & \cdots & f_{N-1} \end{matrix}$$

B. Receiver system

The interference cancellation MMSE-DC receiver in the OFDM system for aeronautical communication is shown in Fig. 2. The system consists of multiple receiver antennas. The received signal from each receiver antenna is separated to remove the guard time and converted from serial to parallel next. After that, this signal will be processed by fast Fourier transform (FFT), the resulting output is signal in frequency domain. Again, this output signal is converted from parallel to serial. The output can be expressed as (5)

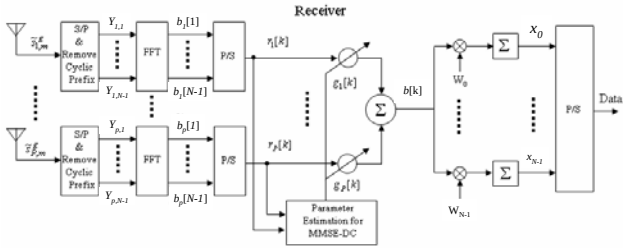

Fig. 2. Block diagram of MMSE-CD receiver in OFDM system.

$$r_p[k] = H_p^{(0)}[k]b_p^{(0)}[k] + \sum_{l=1}^{L} H_p^{(l)}[k]b_p^{(l)}[k] + N_p[k] \quad (5)$$

Eq. (5), let the receive antenna is p antennas, when p=1,2,…,P, $b_p^{(0)}[k]$, b is the required signal, $H_p^{(0)}[k]$ is the frequency response of channel of required signal of p-th receive antennas, $b_p^{(l)}[k]$ is l-th interference signals, $H_p^{(l)}[k]$ is the frequency response of channel consistence with the interference of p-th receive antennas, $N_p[k]$ is Gaussian noise of p-th receive antennas which is equal zero and noise power equal σ_n^2. On the next step, the signal of each receive antenna is summed, so called diversity combiner (DC) and weight with $g_p[k]$. The equation can be given as

$$b[k] = G^H[k]r[k] \quad (6)$$

where r[k] is the signal vector of receive antenna, G[k] is the weight of vector, $G^H[k]$ is the defining of conjugate and transpose of vector G[k]. By using MMSE algorithm detection is

$$MMSE = \min E\left\{ \left| G^H[k]r[k] - b^{(0)}[k] \right|^2 \right\} \quad (7)$$

Also, G[k] in (6) and (7) can be calculated by [3], and expressed as

$$G[k] = (R_r[k])^{-1} H^{(0)}[k] \quad (8)$$

where $H^{(0)}[k]$ is channel frequency response vector P×1, $R_r[k]$ is correlation matrix P×P of receive antenna which is transmitted with same sub-carrier, given by

$$R_r[k] = E\left(r[k]r^H[k]\right) = \sum_{l=0}^{L} H^{(l)H}[k]H^{(l)}[k] + \sigma_n^2 I_P \quad (9)$$

Also, I_P is the identical matrix P×P. The signal b[k] of (6) can be achieved by linear summing of each antenna and weight with MMSE algorithm, called MMSE-DE. After that, the output of b[k] must be despread by product with W_q. The output of each despread is summed, given by

$$x_q = \sum_{k=0}^{N-1} b[k]W_q \quad (9)$$

The x_q must be modulated by QPSK, and it parallel-to-serial converted to recovering the original data.

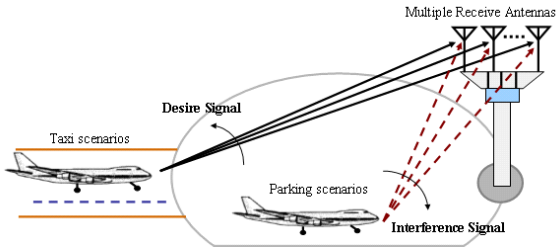

Fig. 3. The communication between aircrafts and an airport ground station.

C. Aeronautical Channel model

The aeronautical channel scenarios consist of several conditions such as en-route scenario, arrival and takeoff scenario, taxi scenario, parking scenario, aircraft flying over ground station [7]. In this paper, only taxi and parking channel scenarios will be considered. The taxi scenario is the applied when the aircraft is on the ground and traveling toward or from the terminal while parking scenario is applied when the aircraft is on the ground and traveling at very slow speed close to the terminal or is parked at the terminal. In Fig. 3, we let the taxi scenario is the channel of

desire signal. In this case, the speed of aircraft approximately about 15m/s. If we use the carrier about 5GHz, the maximum doppler frequency is 250Hz, the channel is Rician fading and the factor *k* is 6.9dB [7]. Again, we let the channel of the parking scenario as shown in Fig. 3 is interference signal. The speed of aircraft about 5.5m/s, at the same carrier, the maximum doppler frequency is 91.7Hz, the channel is Rayleight fading.

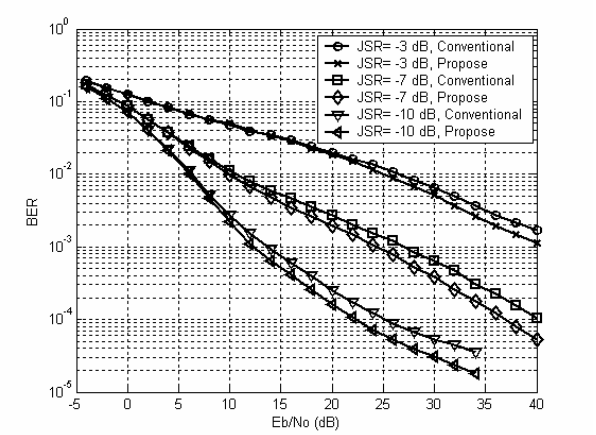

Fig. 4. BER performance of the original OFDM MMSE-DC compared with proposed OFDM system with respect to three receive antennas with JSR is:-3dB, -7dB, and -10dB.

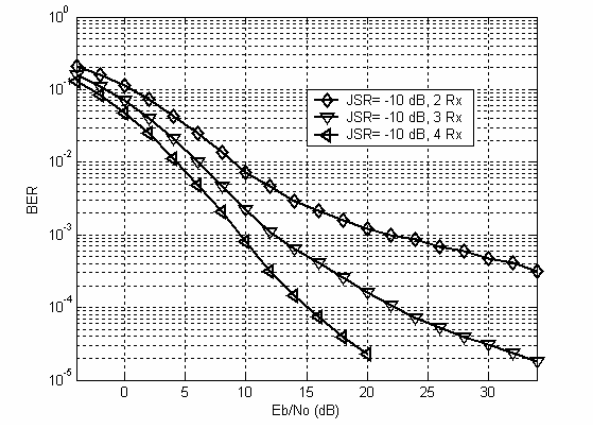
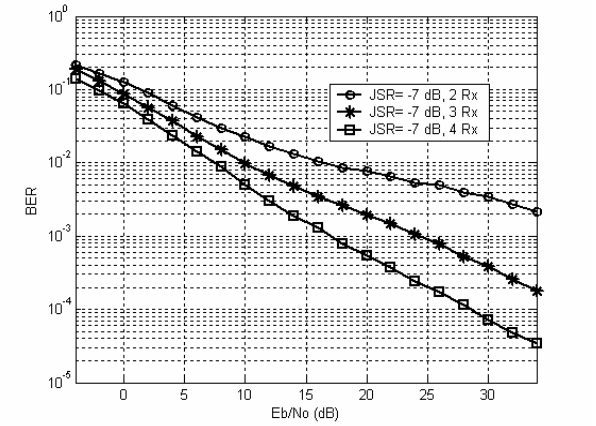


(a)



(b)

Fig. 5. BER performance of proposed OFDM system with respect to different receive antennas, (a) JSR=-10dB and (b)-7dB.

III. Simulation Results

The proposed systems in Figs. 1 and 2 are evaluated by using computer simulation. In the simulation, the system consists of N_C=N=64 carriers, each spread is 7.68kHz from each other, giving a total bandwidth is 492kHz and an OFDM symbol duration of T_{FFT}=130μs. A guard time of T_g=32.5μs and the carrier frequency is 5GHz [7]. Fig. 4 shows the Bit Error Rate (BER) performance of the original OFDM MMSE-DC compared with proposed OFDM system. In this simulation, it used three receive antennas with JSR is -3dB, -7dB, and -10dB, respectively, when JSR=10log(P_I/P_S), also P_I and P_S denotes the average power of interference and desire signal, respectively. In this figure, it can see that the proposed OFDM system give better performance compared with original OFDM MMSE-DC. Proposed OFDM is better than original OMDM MMSE-DC by 3dB at the BER of 10^{-4} for JSR=-7dB and -10dB. The BER performance of proposed OFDM system with respect to different receive antennas for JSR=-10dB and -7dB shown in Fig. 5(a) and (b), respectively. When we use the receive antenna R_x=2, 3, and 4, the BER performance in Fig. 5(a) for JSR=-10dB give better performance compared with Fig. 5(b) for JSR=-7dB. In this case, we can evaluate that the performance of aeronautical communication can be improved by increase the receive antenna at an airport ground station.

IV. Conclusions

We show that when the aircraft is on the ground and traveling on the runway, the communication between an aircraft and ground station will be disturbed from the interference signals. In this paper, an interference cancellation of aeronautical communication is presented. The performance of aeronautical communication can be increased by canceling the interference signals. The simulation results demonstrate that the performance of the system can be improved. When the power of interference signal increased, the JSR will be increased too, in this case the performance of the system can be increased by increasing the receive antenna combined with MMSE-DC algorithm. The performance of aeronautical communication can be increased by improving the ground station without changing the system of aircraft.

***Abstract*— Adaptive multiple input multiple output orthogonal frequency division multiplexing (MIMO-OFDM) system adaptively changes modulation scheme per subcarrier depending on channel state information (CSI) via feedback channel. CSI feedback channel delay including propagation delay, processing delay, frame delay degrades the data capacity of adaptive modulation system. This paper evaluates the two least square (LS) based multi-step autoregressive predictions, high rate prediction (HRP) and low rate prediction (LRP), over severe mobile fading channels and presents an adaptive MIMO-OFDM system with a linear predictor that is robust to the delay and the channel estimation error. Via computer simulation, we verify that LRP based MIMO-OFDM improves data capacity compared to HRP based MIMO-OFDM.**

I. INTRODUCTION

Adaptive OFDM improves data capacity for cellular systems by changing adaptively modulation order per each subcarrier according to the feedback CSI [1,2]. In practical communication systems, the CSI feedback channel has multiple symbol delays, such as processing delay and propagation delay, which result in the CSI mismatch to degrade system performance.

To compensate the multiple symbol delays via feedback channels, several minimum mean square error (MMSE) based autoregressive (AR) high rate prediction (HRP) schemes for adaptive OFDM systems have recently been proposed [3,9-10]. HRP is sensitive to CSI feedback delay d due to its fixed sample span, especially at the high channel estimation error conditions [5]. As a linear prediction filter, this paper chooses least square (LS) rather than MMSE [4], since MMSE is difficult to get the weight vector over time-varying mobile fading. This paper also investigates low rate prediction (LRP) whose sample span for prediction is extensible depending on the delay d. As a result, LRP that has a d times larger sample span than HRP is more robust to the multiple symbol delays [5].

To compensate the multiple symbol delays effectively in adaptive MIMO-OFDM, we employ the low rate prediction (LRP) scheme [5]. We evaluate the two prediction schemes, LRP and HRP, in terms of minimum sum of error squares (MSES) and mean square error (MSE) versus the delay d in MIMO-OFDM channels and verify that LRP based MIMO-OFDM is less sensitive than HRP based MIMO-OFDM over mobile fading channels with a large CSI delay and a small channel estimation signal to noise ratio (CESNR). Via computer simulation, we verify that LRP based MIMO-OFDM improves data capacity over HRP based MIMO-OFDM.

The organization of the rest of the paper is as follows. Section II explains the two fading channel prediction methods, HRP and LRP. Section III addresses the proposed adaptive SISO (single input single output) / MIMO-OFDM system with a multi-step predictor and Section IV demonstrates the simulation results for the proposed adaptive MIMO-OFDM. Finally we conclude this paper in Section V.

II. MULTI-STEP FADING CHANNEL PREDICTION

CSI feedback channel has multiple symbol delays such as processing delay and propagation delay. Hence this paper employs a multi-step channel prediction scheme to mitigate adaptive system performance degradation due to the CSI mismatch by the feedback delay. This paper compares and analyzes the two autoregressive (AR) multi-step prediction schemes, the conventionally well-known high rate prediction (HRP) and the recently proposed low rate prediction (LRP), in multipath fading channels. As an AR prediction filter, LS is used.

A. High Rate Sample Based Multi-step Prediction

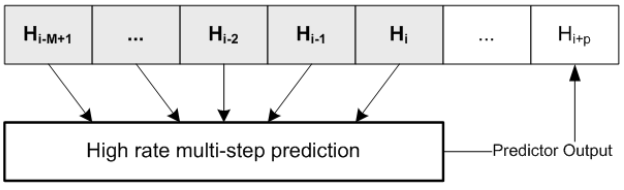

Fig. 1. High rate samples based multi-step prediction.

HRP, described in Fig 1, predicts the future p th channel samples $\hat{H}_{i+p}$ based on the previous contiguous M (=filter length) samples $\{H_i, H_{i-1}, ..., H_{i-(M-1)}\}$, whose sampling rate is the same as the OFDM symbol rate f_s, as follows:

$$\hat{H}_{i+p} = \sum_{j=1}^{M} w_j H_{i-(j-1)}, \quad (1)$$

where p is the prediction step size and w_j is the jth element of HRP weight vector $\mathbf{w}_h = [w_1 \ w_2 \ ... \ w_M]$. The weight vector $\mathbf{w}_h$ is derived by

$$\mathbf{w}_h = \mathbf{\Phi}_h^{-1} \mathbf{z}_h, \quad (2)$$

where $\mathbf{\Phi}_h = \mathbf{U}_h \mathbf{U}_h^H$ is the $M \times M$ autocorrelation matrix of HRP data matrix $\mathbf{U}_h$ [4] (the superscript H denotes the Hermitian transpose) given as

$$\mathbf{U}_h = \begin{bmatrix} H_M & H_{M+1} & \cdots & H_N \\ H_{M-1} & H_M & \cdots & H_{N-1} \\ \vdots & \vdots & \ddots & \vdots \\ H_1 & H_2 & \cdots & H_{N-M+1} \end{bmatrix}.$$

M and N denote the filter length and the number of samples for generating the weight vector, respectively. $\mathbf{z}_h = \mathbf{U}_h \mathbf{d}_h^H$ is the $M \times 1$ cross correlation vector of the data matrix $\mathbf{U}_h$ and the desired output vector $\mathbf{d}_h = [H_{M+1} \ H_{M+2} \ ... \ H_{N+1}]$ [4]. HRP has a fixed sample span M so it is sensitive to CSI feedback delay d [5], especially when the channel estimation error is high.

B. Low Rate Sample Based Multi-step Prediction

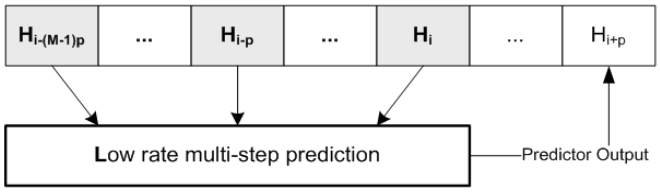

Fig. 2. Low rate samples based multi-step prediction.

LRP, described in Fig. 2, predicts the p th future samples $\tilde{H}_{i+p}$ based on the previous M channel samples whose index difference is p: $\{H_i, H_{i-p}, ..., H_{i-(M-1)p}\}$. That is, the sampling rate of LRP is f_s / p which is p times lower than HRP. H_{i+p} can be obtained by the following equation (3).

$$\tilde{H}_{i+p} = \sum_{j=1}^{M} \tilde{w}_j H_{i-(j-1)p}, \quad (3)$$

where p is the prediction step size and $\tilde{w}_j$ is the jth element of LRP weight vector $\mathbf{w}_l = [\tilde{w}_1 \ \tilde{w}_2 \ ... \ \tilde{w}_M]$ which is obtained from

$$\mathbf{w}_l = \mathbf{\Phi}_l^{-1} \mathbf{z}_l, \quad (4)$$

where $\mathbf{\Phi}_l = \mathbf{U}_l \mathbf{U}_l^H$ is the autocorrelation matrix of data matrix $\mathbf{U}_l$

$$\mathbf{U}_l = \begin{bmatrix} H_{(1+(M-1)p)} & H_{(1+Mp)} & \cdots & H_{(1+(N-1)p)} \\ H_{(1+(M-2)p} & H_{(1+(M-1)p)} & \cdots & H_{(1+(N-2)p)} \\ \vdots & \vdots & \ddots & \vdots \\ H_1 & H_{1+p} & \cdots & H_{(1+(N-M+1)p)} \end{bmatrix} \quad (5)$$

and $\mathbf{z}_l = \mathbf{U}_l \mathbf{d}_l^H$ is the cross correlation matrix of LRP data matrix $\mathbf{U}_l$ and desired output matrix $\mathbf{d}_l = [H_{(1+Mp)} \ H_{(1+(M+1)p)} \ ... \ H_{(1+Np)}]$. LRP that has an expandable sample span dM proportional to the delay d is more robust to CSI feedback delay d than HRP [5].

C. Performance comparison

This paper compares the two LS based prediction schemes, HRP and LRP, in terms of MSES (minimum sum of error squares) $E_{\min}$

$$\begin{aligned} E_{\min} &= E_d - E_{est} \\ &= \sum_{i=M}^{N} |d(i)|^2 - \sum_{i=M}^{N} |d(i \mid \mathbf{u}_i)|^2 \\ &= \sum_{i=M}^{N} |d(i)|^2 - \mathbf{z}^H \mathbf{\Phi}^{-1} \mathbf{z}, \end{aligned} \quad (6)$$

where $E_d = \sum_{i=M}^{N} |d(i)|^2$ is the energy of desired output samples $d(i)$ and $E_{est} = \sum_{i=M}^{N} |d(i \mid \mathbf{u}_i)|^2$ is the energy of estimated output samples $\hat{d}(i \mid \mathbf{u}_i)$ when the ith prediction filter input vector $\mathbf{u}_i = [u_i \ u_{i-1} \ ... \ u_{i-M+1}]$ is given. That is, $\mathbf{u}_i = [H_i \ H_{i-1} \ ... \ H_{i-M+1}]$ for the HRP method and $\mathbf{u}_i = [\tilde{H}_i \ \tilde{H}_{i-p} \ ... \ \tilde{H}_{i-(M-1)p}]$ for the LRP method.

HRP and LRP are compared in Fig. 3 in terms of MSES versus CSI feedback delay in a Vehicular A channel [7]. Assume the mobile speed is 60km/h. Fig. 3 shows that when the delay d is less than 5 there is no big MSES difference between LRP and HRP. But when the delay d is greater than 5, the MSES difference between LRP and HRP gets greater, That is, as the feedback delay increases,

MSES of HRP increases but MSES of LRP is within the range of 10^{-4} to 10^{-2}. Fig. 4 compares MSE of HRP, i.e., $E\left[\left|H_{i+p}-\hat{H}_{i+p}\right|^2\right]$, and MSE of LRP, i.e., $E\left[\left|H_{i+p}-\tilde{H}_{i+p}\right|^2\right]$, for the variation of the CSI feedback delay *d*. We employ Vehicular A channel for fading channel and assume the mobile speed is 60km/h. As the CSI feedback delay increases, the MSE curve for HRP has a steeper slope than that for LRP. From the results in Fig. 3 and Fig. 4, we can confirm that LRP is more robust to the delay *d* than HRP especially in mobile fading channels.

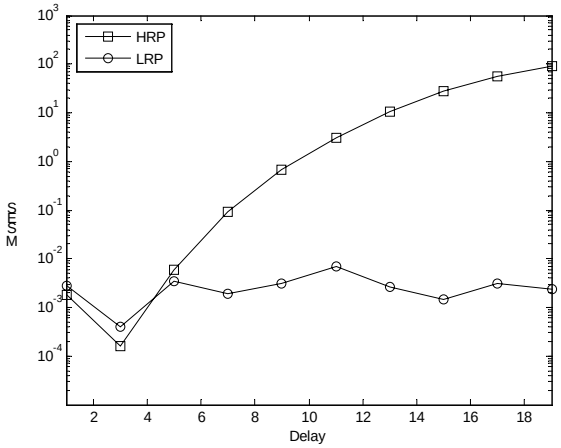

Fig. 3. MSES comparison of HRP and LRP in Vehicular A channel when the mobile speed is 60km/h.

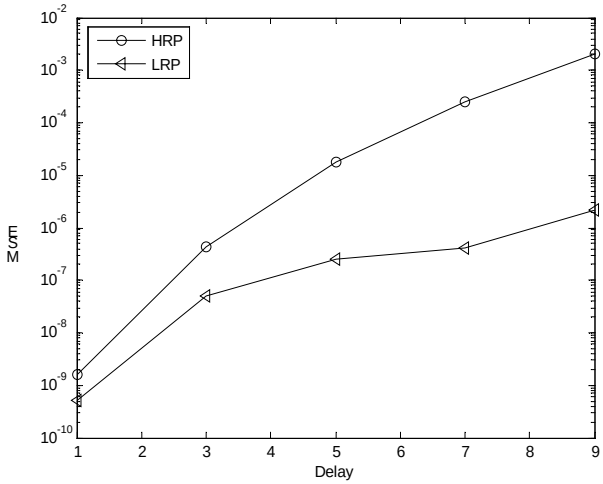

Fig. 4. MSE comparison of HRP and LRP in Vehicular A channel when the mobile speed is 60km/h.

III. ADAPTIVE MIMO-OFDM SYSTEM WITH A PREDICTION FILTER

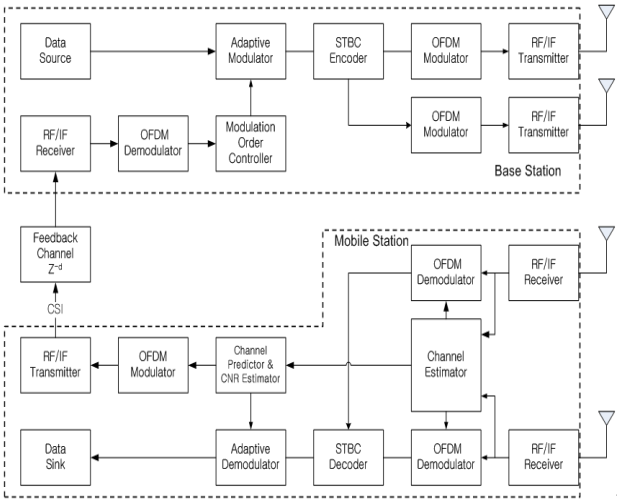

Fig. 5. Adaptive MIMO-OFDM system with a multi-step channel predictor.

A block diagram of adaptive MIMO-OFDM with a multi-step channel predictor is shown in Fig. 5. This paper employs a 2×2 space-time block code (STBC) for MIMO operation [6]. For adaptive operation, we add an adaptive modulator block and a channel predictor block to the fixed MIMO-OFDM system and establish a CSI feedback path with the feedback delay *d*. Mobile station (MS) receiver compensates the CSI damage due to the delay *d* using the multi-step channel predictor. MS feedbacks CSI to its serving base station (BS) and the BS assigns bit loading information per each modulation symbol depending on the CSI.

TABLE 1. SYSTEM PARAMETERS

Parameter	*Value*
bandwidth	20MHz
sampling frequency	25MHz
carrier frequency	5GHz
number of used subcarriers	1536
number of virtual unused subcarriers and DC subcarrier	512
number of total subcarriers	2048
number of transmit antennas	2
number of receive antennas	2
effective symbol period	81.92usec
cyclic prefix length	18.08usec

IV. SIMULATION RESULTS

In this section, we provide simulation results that demonstrate the performance of the proposed SISO / MIMO-OFDM system with a multi-step predictor. In computer simulation, we consider the Jakes model [8]

whose fading parameters are the same as Vehicular A channel model [7]. Assume the mobile velocity is 60km/h. Among the total 2048 subcarriers, the number of used (traffic or pilot) subcarriers is 1536. The adaptive MIMO-OFDM system parameters are shown in Table 2.

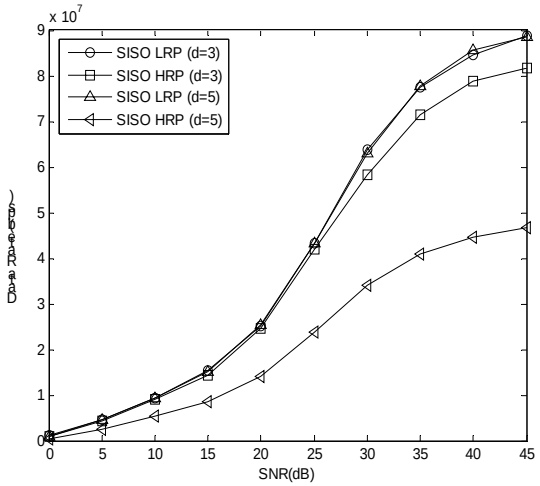

Fig. 6. Data rates of SISO LRP and HRP versus SNR and CSI feedback delay for CESNR 50dB.

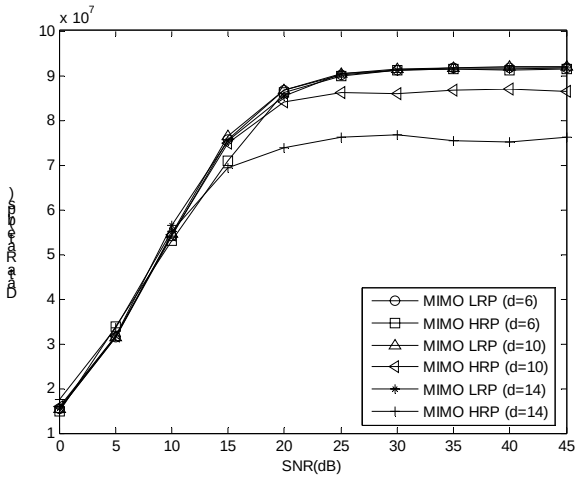

Fig. 7. Data rates of MIMO LRP and HRP versus SNR and CSI feedback delay for CESNR =50dB.

Fig. 6 compares the data rate of SISO LRP and SISO HRP versus signal-to-noise ratio (SNR) when CSI feedback delay varies. Assume CESNR (channel estimation signal to noise ratio) is equal to 50dB. In case of SISO HRP, the maximum allowable data rate (= data capacity) decreases from 82Mbps to 48Mbps when the delay *d* increases 3 to 5. But in case of SISO LRP, the increase of delay does not make a big change of data rate. For SISO LRP, the data capacity is 88Mbps. On the other hand, Fig. 7 compares the data rate of MIMO LRP and MIMO HRP versus signal-to-noise ratio (SNR) when CSI feedback delay varies. Assume also CESNR is set to 50dB. For the space-time diversity gain, MIMO-OFDM assumes constant channel for the two symbol period. For the delay *d*=6, MIMO HRP and MIMO LRP has a similar data capacity of 92Mbps. But as the delay increases while MIMO LRP has no big change of data rate MIMO HRP reduces the data rate a lot. For instance, for *d*=14, MIMO HRP has a reduced data capacity of 76 Mbps and MIMO LRP keeps the maximum data capacity of 92Mbps.

V. CONCLUSION

This paper has presented an adaptive MIMO-OFDM with an LS based linear prediction filter which compensates CSI feedback delay effectively over mobile fading channels. This paper has compared MSES and MSE between the two linear autoregressive prediction schemes, LRP and HRP, and has confirmed that LRP is more robust to the severe MIMO-OFDM channels. Via computer simulation in Vehicular A channels, we verify that LRP based MIMO-OFDM improves data capacity compared to conventionally proposed HRP based MIMO-OFDM.

Abstract- **The future satellite communication systems are required to support the higher transmission data rate for providing the multimedia services by employing the efficient modulation method such as multi-level QAM. However, the employment of conventional single carrier transmission method with multi-level QAM would cause the fatal degradation of signal quality due to the non-linear amplifiers located at the earth station and satellite. To overcome this problem, we have proposed the multi-level QAM-OFDM technique with IDAR method designed for non-linear satellite channel. However, the proposed method could not mitigate the non-linear distortion sufficiently when modulation level becomes higher such as 64QAM. This paper proposes the combined scheme for PAPR reduction method employed at the transmitter and OFDM-IDAR method employed at the receiver so as to enable the usage of higher multi-level QAM method. The proposed method can achieve the higher transmission data rate with keeping the better bit error rate performance even in the non-linear satellite channel.**

I. INTRODUCTION

One of the disadvantages of using the OFDM is that its time domain signal has the larger PAPR (Peak to Average Power Ratio), which causes the degradation of BER (Bit Error Rate) performance in the non-linear amplifier [1]. From this reason, the OFDM has been considered as unsuitable transmission technique for the non-linear satellite channel, although it has a potential capability to improve the transmission data rate by employing the multi-level QAM with less complexity of transmitter and receiver.

To solve PAPR problem in the OFDM scheme, we proposed the OFDM-IDAR (Improved Decision Aided Reconstruction) method, which can mitigate the non-linear distortion at the receiver and achieve the higher transmission data rate with keeping the better BER performance even in the satellite channel [2]. However, the proposed OFDM-IDAR method has some limitation on the usage of higher level of modulation method such as 64QAM for achieving the higher transmission data rate. Because its higher level of modulation method causes a lot of decision error due to the non-linear amplifiers located at the transmit earth station and satellite, and the IDAR method could no more mitigate the non-linear distortion sufficiently. To reduce the non-linear distortion, it is required to improve the PAPR performance as much as possible for the OFDM signal at the transmission side. If the PAPR performance of OFDM signal can be improved somehow at the transmission side, the non-linear distortion can be reduced and accordingly the IDAR method could achieve the better BER performance at the receiver even when the higher level of modulation method is employed. In this paper, we propose the OFDM-IDAR method in conjunction with the PAPR reduction method, which allows the employment of higher level of modulation method in the non-linear satellite channel. As for the PAPR reduction method, we propose the improved DSI (Dummy Sub-carrier Insertion) method [3], which can achieve the better PAPR performance than the conventional DSI method [4].

In this paper, Section 2 firstly presents the satellite system model including the non-linear amplifiers at the earth station and satellite. Section 3 proposes the improved dummy sub-carrier insertion (IDSI) method as the PAPR reduction method at the transmit earth station and also propose the IDAR method as the mitigation method of non-linear distortion at the receive earth station. Section 4 presents the various computer simulation results to verify the effectiveness of proposed OFDM-IDAR with IDSI method in the non-linear satellite channel, and Section 5 draws some conclusions.

II. SATELLITE SYSTEM MODEL

Figure 1 shows the typical satellite system model assumed in the following evaluations. The non-linear amplifiers assumed at the transmit earth station and satellite are the Solid State Power Amplifier (SSPA) and Traveling Wave Tube Power Amplifier (TWTA), respectively. The input-output relationships of AM-AM and AM-PM characteristics both for SSPA and TWTA are assumed in the following evaluations [2]. The downlink signal from the satellite to the received earth station, which corresponds to the output signal of TWTA, is given by the following equation.

$$s_{dw}(t) = F_c\left[\left|s(t)\right|\right] \cdot e^{j\left\{\arg(s(t)) + \Phi_c(s(t))\right\}} \qquad (1)$$

where $s(t)$ is the modulated OFDM signal, and $F_c[\,]$ and $\Phi_c[\,]$ are the composite AM-AM and AM-PM conversions characteristics of SSPA and TWTA as shown in Fig.1.

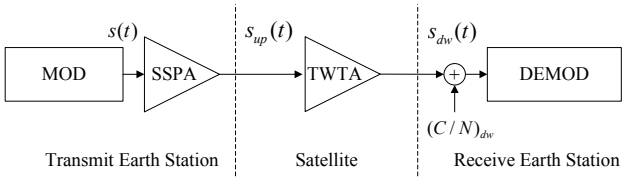

Figure 1. Satellite system model.

III. PROPOSAL OF OFDM-IDAR WITH IMPROVED DSI METHOD

A. Proposed DSI Method at Transmit Earth Station

This section proposes the improved DSI (IDSI) method, which can achieve better PAPR performance as compared with the conventional DSI method. Fig.2 shows the structure of proposed OFDM symbol represented in the frequency domain. The OFDM symbol consists of *M* data sub-carriers and *L* dummy sub-carriers that are placed at the both ends of data sub-carriers.

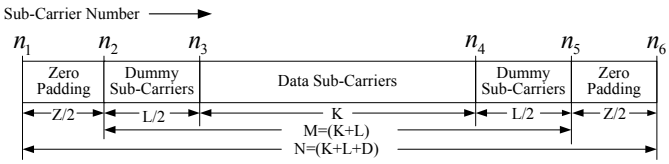

Figure 2. Structure of proposed OFDM symbol in frequency domain.

Figure 3 shows the block diagram of proposed IDSI method at the transmission side that employs the time-frequency domains swapping algorithm for the determined phase values for the dummy sub-carriers. In the proposed method, the target PAPR and the maximum number of iterations are firstly set. From Fig.3, the modulated data sub-carriers and dummy sub-carriers in the frequency domain are converted to the time domain signal by *IFFT*. The time domain signal at the *i-th* iteration is given by the following equation.

$$x_k^{(i)} = \frac{1}{\sqrt{N}} \sum_{n=0}^{N-1} X_n^{(i)} e^{j\frac{2\pi kn}{N}} \tag{2}$$

where N is the number of *IFFT* points and $X_n^{(i)}$ is the frequency domain data including the data, dummy and null sub-carriers at the *i-th* iteration, which is given by,

$$X_n^{(i)} = \begin{cases} A_n & n_3 \le n \le n_4 - 1 \\ D_n^{(i)} & n_2 \le n \le n_3 - 1 \text{ and } n_4 \le n \le n_5 - 1 \\ 0 & \text{others (zero padding)} \end{cases} \tag{3}$$

where A_n is the frequency data for information and $D_n^{(i)}$ is the frequency data for dummy sub-carriers at *i-th* iteration. At the initial iteration (*i=0*), the frequency data for all dummy sub-carriers are given by 0.

In the time-frequency domain swapping algorithm, the error signal is calculated by the following equation in which the sampled time domain signal is detected as the error signal only when its amplitude level is greater than a certain reference level of *S*.

$$e_k^{(i+1)} = \begin{cases} x_k^{(i)} & \text{if } \left|x_k^{(i)}\right| \ge S \\ 0 & \text{if } \left|x_k^{(i)}\right| < S \end{cases} \quad (0 \le k \le N-1) \tag{4}$$

where the reference level *S* is usually decided on the basis of the average power of input signal. The time domain error signal given by (4) is converted to the frequency domain signal by *FFT*, which is given by the following equation.

$$E_n^{(i+1)} = \frac{1}{\sqrt{N}} \sum_{k=0}^{N-1} e_k^{(i+1)} \cdot e^{-j\frac{2\pi nk}{N}} \quad (0 \le n \le N-1). \tag{5}$$

By using (5), the frequency domain signal both for the data and dummy sub-carriers to be used at the next iteration *(i+1)* is given by the following equation.

$$D_n^{(i+1)} = \alpha \cdot e^{j\left[\arg\left\{D_n^{(i)} - E_n^{(i+1)}\right\}\right]} = \alpha \cdot e^{j\theta_n^{(i)}}$$
$$n_2 \le n \le n_3 - 1 \text{ and } n_4 \le n \le n_5 - 1 \tag{6}$$

where α is the constant amplitude level which can be decided by the averaged amplitude level of data sub-carriers. Here, it should be noted that these determined phases are carried out only for the dummy sub-carriers and the data sub-carriers are kept as the same as the original data information. In the time-frequency swapping algorithm, (2) to (6) are repeated up to reach either the predetermined PAPR or the predetermined number of iterations.

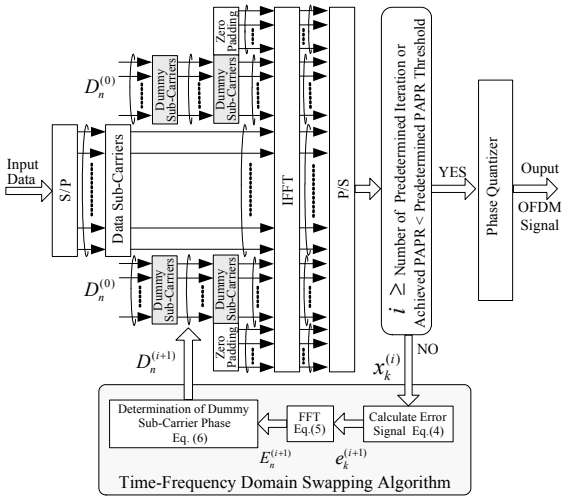

Figure 3. Structure of proposed IDSI method.

The phase value of $\theta_n^{(i)}$ for each dummy sub-carrier, which is obtained by the above time-frequency domain swapping algorithm, has the continuous (analogue) value because of using the time-frequency domains swapping algorithm. However, the IDAR method is required to use the decision data at the receiver for the reconstruction of inter-modulation noise. If the continuous phase is used for each dummy sub-carrier, the accuracy of decision phase at the receiver would be degraded relatively and the complexity of IDAR receiver would be increased. From these reasons, the continuous phase value is quantized to the discrete value at the "Phase Quantizer" as shown in Fig.3. The output of "Phase Quantizer" can be given by the following equation.

$$\tilde{\theta}_n^{(i)} = \min_{k=1\sim J} \left|\theta_n^{(i)} - \tilde{\theta}_k\right| \tag{7}$$

where $\tilde{\theta}_k$ is the predetermined discrete phase value and given by the following equation.

$$\tilde{\theta}_k = 2\pi \cdot \frac{(k-1)}{J} \quad k = 1 \sim J \tag{8}$$

where the discrete phase value is given by equal phase step from *0* to 2π and *J* is the number of discrete phase value. By using (7), the transmitted dummy sub-carrier is given by the following equation.

$$X_n^{(i)} = \alpha \cdot e^{j\tilde{\theta}_n^{(i)}} \ , n_2 \le n \le n_3 - 1 \ and \ n_4 \le n \le n_5 - 1 \qquad (9)$$

Here it should be noted that if J is taken by larger number, the PAPR performance could be improved. However, the complexity of IDAR method at the receiver side would be increased because the decision of dummy sub-carriers is required to perform by using the larger number of discrete phase. The selection of optimum value for J is evaluated in Section 4.

B. OFDM-IDAR Method for Satellite Channel

Figure 4 shows the structure of receiver for the proposed OFDM-IDAR with IDSI method. In Fig.4, the received downlink RF signal $s_{dw}(t)$ given in (1) is first down converted to the base band signal and digitized by A/D converter. The received time domain sampled signal after removing the guard interval (GI) is given by the following equation.

$$r_k = s_{dw,k} + w_k = y_k + i_k + w_k \qquad (10)$$

where, $s_{dw,k}$, w_k, y_k and i_k represent the output signal of TWTA, additive noise in the downlink, transmitted desired signal and inter-modulation noise on the *k-th* time domain sampled signal, respectively. Here, the inter-modulation noise is assumed to add the desired signal y_k linearly. It should be noted that the inter-modulation noise at the output of non-linear amplifier is unable to express separately as given in (10), because it is strongly related to the desired signal y_k. However, the inter-modulation noise is reconstructed separately in the IDAR method by using the decision data at the receiver. Although it is inappropriate to express the inter-modulation noise separately, (10) is given here just as the assumption so as to explain the following IDAR algorithm clearly. The received time domain sampled signal given by (10) is converted to the frequency domain signal by *FFT*, which is given by the following equation.

$$R_n = Y_n + I_n + W_n \qquad (11)$$

where, the capital letter represents the frequency domain signal, which corresponds to its small letter given by (10) in the time domain. The decision for data information and dummy sub-carriers can be made by the following equation.

$$\hat{S}_n = \min_X \left| R_n - X_n \right| \qquad (12)$$

where $\hat{S}_n$ is the decision data both for the data and dummy sub-carriers at the *n-th* sub-carrier. Here it should be noted that the decision for dummy sub-carrier is made by using (7).

The decision data in the frequency domain is converted to the time domain signal $\hat{s}_k$ by *IFFT*, which corresponds to the reconstructed transmitted time domain signal. In the IDAR method, the time domain signal $\hat{s}_k$ is used for the reconstruction of inter-modulation noise. This is based on the fact that the OFDM time domain signal converted from the decision data in the frequency domain, which includes even some decision errors, would be almost the same as the original time domain signal without error [2]. From this fact, the inter-modulation noise can be reconstructed by using the decision data in the time domain.

By using the time domain signal $\hat{s}_k$, the output time domain signal of SSPA and TWTA can be reconstructed by using the same manner as processed at the earth station and satellite. In the IDAR method, the operations of non-linear amplifiers both for the SSPA and TWTA are conducted on the digital sampled data by assuming the same AM-AM and AM-PM conversion characteristics as that operated in the radio frequency. The time domain signal at the output of SSPA and TWTA as shown in Fig.4 is given by the following equation.

$$\hat{s}_{dw,k} = F_C\left[\left|\hat{s}_k\right|\right] \cdot e^{j\left\{\arg(\hat{s}_k) + \Phi_C\left(\left|\hat{s}_k\right|\right)\right\}} \qquad (13)$$

where, $\hat{s}_k$ is the time domain signal converted from the frequency domain decision data given in (12), F_C and Φ_C are the AM-AM and AM-PM conversions characteristics which are the composite characteristics of SSPA and TWTA. Here, the composite characteristics of SSPA and TWTA can be estimated by using the low PAPR preamble symbols. By using (13), the inter-modulation noise incurred at the SSPA and TWTA can be estimated by the following equation.

$$\begin{aligned} \hat{d}_k &= \hat{s}_{dw,k} - \hat{s}_k \\ &\approx \hat{s}_k + \hat{i}_k - \hat{s}_k \approx \hat{i}_k \end{aligned} \qquad (14)$$

The inter-modulation noise given by (14) is then converted to the frequency domain signal $\hat{C}_n$ by *FFT*. By subtracting $\hat{C}_n$ from (11), the frequency domain signal coped with the inter-modulation noise can be obtained by the following equation.

$$\begin{aligned} \hat{R}'_n &= R_n - \hat{C}_n = Y_n + \left\{ I_n - \hat{I}_n \right\} + W_n \\ &\approx Y_n + W_n \end{aligned} \qquad (15)$$

The above procedures are repeated until the better performance can be achieved in the IDAR method.

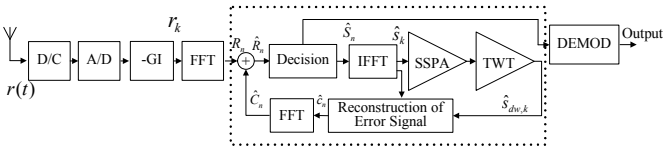

Figure 4. Structure of proposed receiver for OFDM-IDAR with IDSI method.

IV. PERFORMANCE EVALUATIONS

This section presents the various computer simulation results to demonstrate the performance of OFDM-IDAR with IDSI method in the non-linear satellite channel. In the following evaluation, the uplink C/N is assumed to be the noise free condition and only the downlink noise is added to the received signal. The input back-off (IBO) for the transmit earth station amplifier of SSPA is fixed by – 4 dB.

Figure 5 shows the BER performance for the proposed method when changing the number of discrete phase J for the "Phase Quantizer" as shown in Fig.3. In the figure, the BER performance for the case of continuous phase is also shown. In the simulations, IBO for satellite TWTA is taken by -6 dB and the downlink C/N is 26 dB. From the figure, it can be observed that the BER performance of proposed method is almost the same as the case of continuous phase when J is larger than 18. From these results, the following simulation for IDSI method is assumed to use 18 as the number of discrete phase.

Figure 6 shows the PAPR performances for the proposed IDSI and conventional OFDM methods. In the figure, the PAPR performance with the case of continuous phase is also shown. The PAPR performance is evaluated by using the Complementary Cumulative Distribution Function (CCDF). From the figure, it can be seen that the PAPR performance for the IDSI method can be improved as increasing the number of discrete phase, while the performance is almost the same as the case of continuous phase when the number of discrete phase is 18. From these results, J is assumed to use 18 in the following evaluations for the proposed method.

TABLE I SIMULATION PARAMETERS.

Allocated bandwidth	26MHz
Modulation method	64QAM
Detection method	Coherent
No. of *FFT* points (N)	512
No. of sub-carriers (M+L)	128
Symbol duration	4.92μs
Guard interval	0.5μs
No. of dummy sub-carriers (L)	24
Number of discrete phases (J)	18
Transmission data rate	115.1Mbit/s

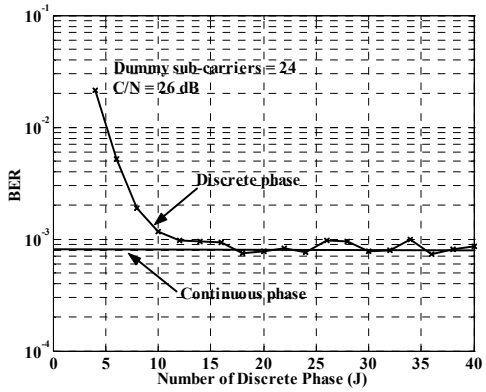

Figure 5. BER performance when changing the number of discrete phase.

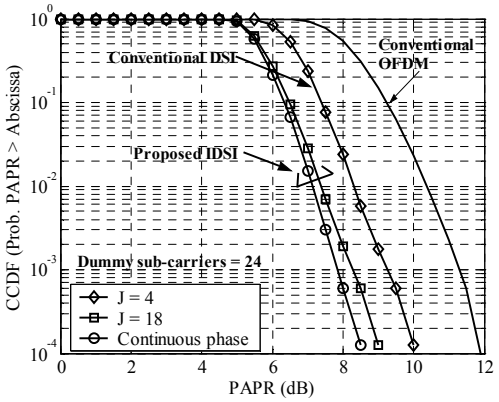

Figure 6. PAPR performance.

Figure 7 shows the BER performances for the conventional single carrier (SC), OFDM-IDAR and proposed OFDM-IDAR with IDSI methods when changing the downlink $(C/N)_{dw}$. In the simulation, the optimum IBO of satellite TWTA for these methods are taken by -15 dB, -6 dB and -6 dB, respectively based on the optimized IBO [2]. From the figure, it can be observed that the proposed method can achieve much better BER performance than that for the conventional SC and OFDM-IDAR methods of which BER performances have error floor at the higher C/N. From these results, it can be concluded that the proposed OFDM-IDAR with IDSI method could achieve the higher transmission data rate with keeping the better BER performance in the non-linear satellite channel.

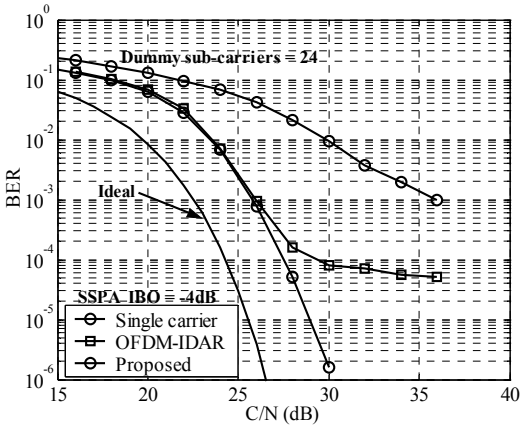

Figure 7. BER performance when changing C/N.

V. CONCLUSIONS

This paper proposed the OFDM-IDAR with IDSI method, which can reduce the PAPR performance at the transmitter by using the proposed IDSI method and can mitigate the non-linear distortion at the receiver by using the IDAR method, respectively. This paper presented various computer simulation results to verify the effectiveness of proposed method in the non-linear satellite channel. From the computer simulation results, we confirmed that the proposed method could achieve the higher transmission data rate with keeping the better BER performance in the non-linear satellite channel.

***Abstract*- In this paper, a new scheme for phase shifter implemented on phase locked loop (PLL) is proposed. It can be accomplished by placing a gain controller either between a loop filter and a VCO or between a summing circuit and an integrator of a conventional PLL. This gain controller is employed to control phase shifting where the phase shift is inversely proportional to its gain. The advantage of this technique is that the phase shift is not a function of the running frequency of a VCO. Hence, the identical phase shifters can be achieved. In addition, the proposed scheme is applied for a QPSK modulator to illustrate its practical application where the experimental results confirm well with the theoretical expectation.**

I. INTRODUCTION

PLL is well known to be one of negative feedback system applications. It is employed in many fields, such as in communication system for FM modulation, FM demodulation, frequency synthesizer, frequency doubler, frequency multiplier, and frequency divider. Also in control system, it is used for phase synchronize to deliver power to motor and in power electronic for phase synchronize to control on-off switched.

Recently, A.W. Houghton and P.V. Brennan [1] proposed phase shifter for application in antenna beam steering by PLL. This proposed technique is based on the summing between input feeding voltage and output phase error voltage. Although it is quite simple; however, the disadvantage of such method is that phase shift is dependent directly on the running frequency (ω_r) of VCO. In addition, this method can be applied for the case that error frequency is small. When the difference between frequency input (ω_i) and frequency running (ω_r), ($\omega_i - \omega_r$) are large, the accuracy of this method thus decreases.

In this paper, an alternative technique to shift phase of signal is proposed which is based on gain adjustment. The proposed system can be easily implemented by adding a gain controller to the conventional PLL. The obtained phase output is found to be proportional to gain of this gain controller. Also, the proposed phase shifter with PLL technique can provide an accurate result because phase difference is directly determined without any approximation. In addition, the phase shifting is not dependent on the frequency running (ω_r) of VCO. Hence, the phase shifters whose phase shifting characteristics are identical can be easily constructed.

Moreover, the phase shift of the proposed technique can be electronically controlled. It is accomplished by constructed the gain controller with devices such as OTA. For this case, gain of this controller is adjusted by the biasing current which results in phase shifting be electronically controlled.

To verify the validation of the proposed method, the experiment is established by using a commercial PLL IC4046. Furthermore, this proposed phase shifter is modified to be QPSK modulator where the experimental results confirm the theoretical expectation.

The organization of this article is given as follows. The brief review of PLL is discussed in section II. In section III, the phase shifter that is proposed by [1] is described and followed with the proposed technique. The application of the proposed PLL for a QPSK modulator is explained in section IV. The experimental results are demonstrated in section V. Finally, the conclusions are given in section VI.

II. PRINCIPLE OF PLL

In this section, a brief review of a conventional PLL as shown by the block diagram in Fig.1 is given. It is noted that the notations in Fig.1 are

$\phi_i(s)$: Laplace transform of phase input function ($\phi_i(t)$)

$\phi_o(s)$: Laplace transform of phase output function ($\phi_o(t)$)

$\varepsilon(s)$: Laplace transform of phase error ($\varepsilon(t)$)

$V_L(s)$: Laplace transform of loop filter output ($v_L(t)$)

$\omega_o(s)$: Laplace transform of frequency output of VCO ($\omega_o(t)$)

$F(s)$: Transfer function of loop filter

$I(s)$: Laplace transform of Integrator $I(t)$

$\omega_r(s)$: Laplace transform of frequency running of VCO in PLL.

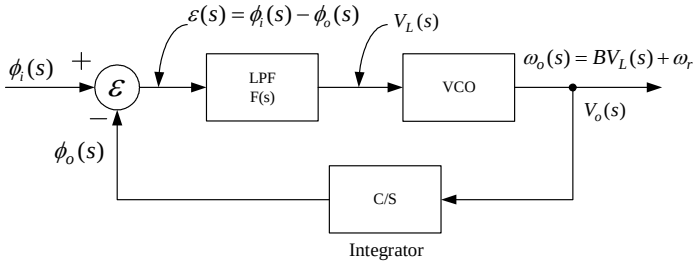

Figure 1. Block diagram of a conventional PLL.

From Fig. 1, the relationship of the system can be written as

$$\frac{BCF(s)}{S}\phi_o(s)+\phi_o(s)=BCF(s)\phi_i(s)+\omega_r(s) \quad (1)$$

where B is the sensitivity of VCO and C is gain of integrator. By substituting a transfer function of the loop filter as $F(s)=\frac{A}{1+GS}$, where A is gain of the loop filter, into (1), it then yields

$$\frac{ABC}{S(1+GS)}\phi_o(s)+\phi_o(s)=\frac{ABC}{S(1+GS)}\phi_i(s)+\omega_r(s). \quad (2)$$

For convenience, let $D = ABC$ and then (2) is rewritten to be

$$GS^2\phi_o(s)+S\phi_o(s)+D\phi_o(s)=D\phi_i(s)+GS^2\omega_r(s)+S\omega_r(s). \quad (3)$$

By taking inverse Laplace transform to both sides of (3), it thus becomes

$$G\frac{d^2\phi_o(t)}{dt^2}+\frac{d\phi_o(t)}{dt}+D\phi_o(t)=D\phi_i(t)+G\frac{d^2\omega_r(t)}{dt^2}+\frac{d\omega_r(t)}{dt}. \quad (4)$$

Since $\omega_r(t)$ is not a function of time, the first and second derivative of this term (shown in the right-side of (4)) is zero. Therefore,

$$G\frac{d^2\phi_o(t)}{dt^2}+\frac{d\phi_o(t)}{dt}+D\phi_o(t)=D\phi_i(t). \quad (5)$$

From (5), the solution for $\phi_o(t)$ can be determined by solving this differential equation. In general, $\phi_o(t)$ is composed of two parts which are homogeneous solution (natural response) and particular solution (force response). For this work, only steady state response is of interest, the natural response is therefore ignored. To determine the force response, let $\phi_i(t)$ be assumed as follows

$$\phi_i(t)=\omega_i t+\theta_i \quad (6)$$

where ω_i is an input frequency. Then $\phi_o(t)$ has the following form,

$$\phi_o(t)=at+b \quad (7)$$

where *a*, *b* are constant.
By replacing $\phi_o(t)$ shown in (7) into (5), hence

$$\phi_o(t)=\omega_i t+\theta_i+\frac{\omega_i}{D}. \quad (8)$$

Therefore,

$$\varepsilon(t)=\phi_i(t)-\phi_o(t)=-\frac{\omega_i}{D} \quad (9)$$

where $\varepsilon(t)$ is phase difference between input and output vary with $-\omega_i/D=-\omega_i/ABC$. As can be seen, the phase difference $\varepsilon(t)$ can be adjusted by A, B and C.

III. PHASE SHIFTER BASED PLL

Recently, A.W. Hougton et al. [1] proposed a phase shifter based on PLL where its application is for antenna beam forming. The block diagram of this work can be depicted as Fig. 2.

In similar to the analyses of the PLL shown in Fig. 1, the error phase voltage of [1] is

$$\varepsilon(t)=\frac{\omega_i-C\omega_r}{ABC}+\frac{v_i}{A}. \quad (10)$$

It is seen in (10) that error phase voltage is proportion to ω_i, ω_r and v_i. However, this scheme cannot provide an accurate phase shift since the ω_r term is difficult to be determined.

To improve this limitation, an alternative technique to shift phase is proposed as given in Fig. 3. As can be seen, the gain controller which can be placed at one of these positions which are either between the loop filter and the VCO or between the summing circuit and the integrator. By selecting gain of the gain controller be inversely proportional to v_i, the phase shift of the proposed scheme is found to be proportional to voltage input as given by

$$\varepsilon(t)=\frac{-v_i\omega_i}{ABC}. \quad (11)$$

It is noted that, this gain controller can be either voltage amplifier or divider circuits.

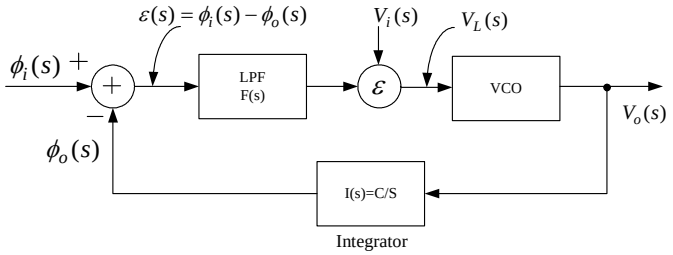

Figure 2. Block diagram of the phase shift scheme proposed by [1].

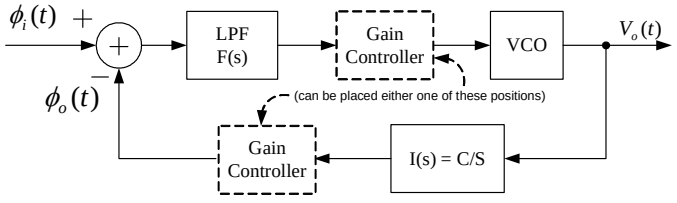

Figure 3. The proposed phase shift scheme.

IV. THE PROPOSED QPSK MODULATOR

Based on the proposed phase shift scheme described in previous section, the application for QPSK modulator is experimented. The proposed phase shifter based on PLL is employed to be the phase detector for $0°-180°$ of phase range. For the case of conventional QPSK signal, 4 phases required for modulating signals are selected to be $45°$, $135°$, $-45°$, and

$-135°$. The experimented circuit of the QPSK modulator is shown in Fig. 4. As shown in Fig. 4, the circuit depicted inside the dash line is the gain controller which can shift phase by adjusting its gain. In addition, the design of the modulation codes are given in Table I.

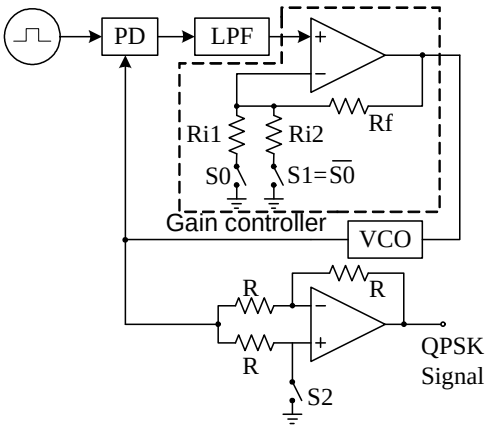

Figure 4. The proposed QPSK scheme.

TABLE I
MODULATION CODE DESIGN

θ	D1	D0	A	S0	S1($\overline{S0}$)	S2
45	0	0	A0	ON	OFF	OFF
135	0	1	A1	OFF	ON	OFF
-45	1	0	A0	ON	OFF	ON
-135	1	1	A1	OFF	ON	ON

As shown in Table I, the switch S0 is controlled by D0 (close when logic D0 = 1 and open when logic D0 = 0). Contrarily, the switch S1 is controlled by $\overline{D0}$, its operation is thus opposite to that of S0. For the switch S2, it is controlled by logic D1 where on and off operation (when logic D1 = 1 and 0, respectively) of this switch controls gain of the amplifier to be -1 or 1, respectively.

V. EXPERIMENTAL RESULTS

To confirm the proposed phase shifter by PLL as mentioned above, the experiment is setup by using a commercial PLL IC4046 as the circuit shown in Fig. 5. It is noted that R1= 50KΩ, R2=50KΩ, R3=1KΩ, Ri=1KΩ, C1=1nF, and C2=0.1μF are employed in this circuit. The results of phase shift for the 49KHz and 50KHz running frequency are illustrated in Fig. 6. It is obvious that the phase shifting characteristic of the proposed technique is independent on the running frequency. In addition, the phase shift is shown to be inversely proportional to gain of the gain controller.

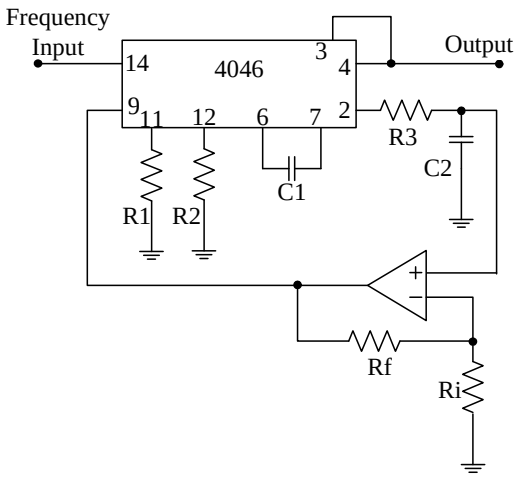

Figure 5. The experiment phase shifter using IC4046.

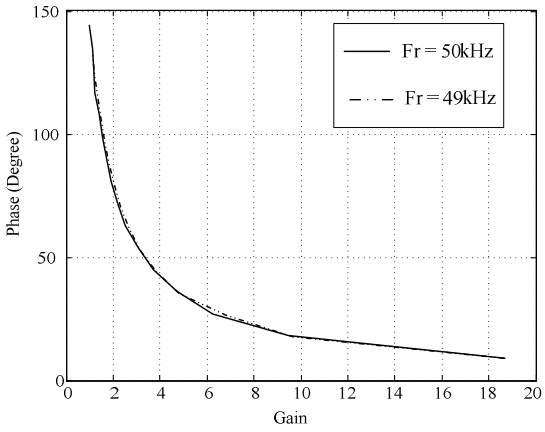

Figure 6. Phase shifting versus controller gain varying of the proposed scheme for running frequency is 49KHz and 50KHz.

For the experiment of the QPSK modulation, the proposed QPSK scheme shown in Fig. 4 is setup with IC XR-2206 for a VCO, X-OR for a phase detector and first order RC for a loop filter as shown in Fig. 7. The example of experimental result is shown in Fig. 8-10. The obtained QPSK signals therefore confirm the application of the proposed phase shift scheme in practical.

VI. CONCLUSIONS

A new scheme for phase shifting is proposed in this work. The concept of the proposed technique to control phase shifting is based on gain of a gain controller. The gain controller is chosen to have its gain be inversely proportional to the input voltage. In the conventional PLL circuit, this gain controller can be placed either between the loop filter and the VCO or between the integrator and the summing circuit. The phase output of the proposed scheme is found to be independent on the running frequency. The identical phase shifter circuits therefore can be achieved. For practical application, the proposed phase shifting scheme has been applied for the QPSK modulator where the experimental result confirms the contribution of the proposed technique.

***Abstract*— In this paper, the bit error rate (BER) performance of ultra wideband (UWB) communications with matched filter and correlation receivers are analyzed. The rectangular passband, modulated rectangular and modulated Gaussian waveforms, which is satisfied the UWB signal definition and Federal Communications Commission (FCC) indoor and outdoor limit spectral masks, are used as the transmitted UWB signal. The complex form of Friis' transmission formula is considered as the UWB free space channel. Therefore, the distortion effects caused from the channel are included. The BER performance of each waveform is shown and compared. The results are discussed in the conclusion.**

I. INTRODUCTION

An ultra wideband (UWB) radio technology has become an important topic for microwave communication because of its low cost and low power consumption potentials [1]-[3]. The UWB differs from the convectional narrow band radio frequency (RF) and spread spectrum (SS) technologies. The UWB uses an extremely wideband of RF spectrum to transmit the data with very short pulses and power spectral density (PSD) in the range of ultra wide frequency spectrum instead of using narrow carrier frequency in traditional RF technologies. The UWB is a unique and new usage of recently legalized frequency spectrum. The UWB technology is specified the frequencies ranging from 3.1 GHz to 10.6 GHz by Federal Communications Commission (FCC) [4]. The FCC defined the UWB signal as those, which have a fractional bandwidth equal or greater than 0.20, or occupied bandwidth equal or greater than 500 MHz.

The Friis' transmission formula [5] is widely used to calculate the free space path loss for narrow band communications. After that, the complex form of Friis' transmission formula is developed for UWB communications [6]-[8]. The matched filter and correlation receivers are used as the UWB receivers [9]-[12]. Although, the performances of UWB communications are analyzed [13], [14], there are no considerations about the FCC regulation of UWB signal and distortion of UWB signal caused by channel. After that, the rectangular waveform distorted by UWB free space channel is used to derive the theoretical BER performance [15]. However, there are no considerations about other causal waveforms.

In this paper, the BER performance of UWB communications with matched filter and correlation receivers are analyzed. The rectangular passband, modulated rectangular and modulated Gaussian waveforms, which is satisfied the UWB signal definition and FCC indoor and outdoor limit spectral masks [16], are used as the transmitted UWB signal. The complex form of Friis' transmission formula is considered as the UWB free space channel. The spectral density of received signal considering the distortion caused by free space channel is evaluated. At the receiver, the matched filter and correlation receivers with frequency transfer functions, which is satisfied the constant noise power condition between the input and output, are used. The BER performance of each waveform is shown and compared.

This paper is organized as follows. Sections 2 and 3, the UWB waveform models and analysis of BER performance are briefly discussed, respectively. Next the analysis results are illustrated in Sec. 4. Finally, the conclusions are discussed in Sec. 5.

II. UWB WAVEFORM MODELS

For UWB waveforms, the rectangular passband, modulated rectangular and modulated Gaussian waveforms are considered as the UWB transmitted waveform (v_{t}) in time domain and its spectral density (V_{t}) in frequency domain. These waveforms can satisfy the FCC definition of UWB signal and FCC spectral masks for indoor and outdoor limits. The parameters obtained from maximum bandwidth, amplitude and average power optimizations, which is proposed in [16], are used.

A. Rectangular Passband Waveform

The rectangular passband transmitted waveform in time domain and its spectral density function are given by

$$v_{\mathrm{t}}(t) = \frac{A}{f_{\mathrm{b}}}[f_{\mathrm{H}}\mathrm{sinc}(2f_{\mathrm{H}}t) - f_{\mathrm{L}}\mathrm{sinc}(2f_{\mathrm{L}}t)], \quad (1)$$

$$V_{\mathrm{t}}(f) = \begin{cases} \frac{A}{2f_{\mathrm{b}}} & ||f| - f_{\mathrm{c}}| \le \frac{f_{\mathrm{b}}}{2} \\ 0 & ||f| - f_{\mathrm{c}}| > \frac{f_{\mathrm{b}}}{2} \end{cases}, \quad (2)$$

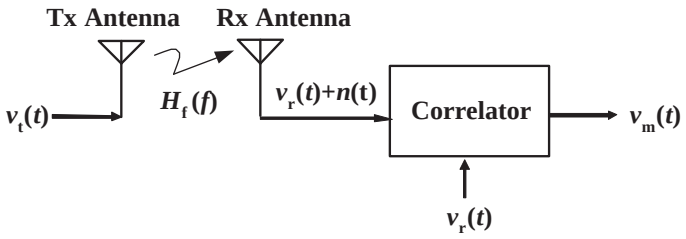

Fig. 1. Block diagram of matched filter receiver system.

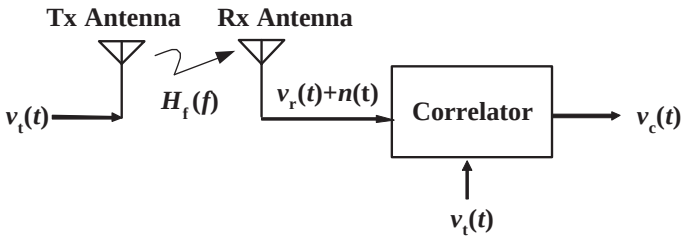

Fig. 2. Block diagram of correlation receiver system.

where A is the maximum amplitude, $f_{\rm b}$ is the occupied bandwidth, $f_{\rm c}$ is the center frequency, $f_{\rm L} = f_{\rm c} - f_{\rm b}/2$ and $f_{\rm H} = f_{\rm c} + f_{\rm b}/2$ are the minimum and maximum frequencies.

B. Modulated Rectangular Waveform

The modulated rectangular transmitted waveform in time domain and its spectral density function are given by

$$v_{\rm t}(t) = \begin{cases} A\sin(2\pi f_{\rm c}t) & |t| \le \frac{t_{\rm b}}{2} \\ 0 & |t| > \frac{t_{\rm b}}{2} \end{cases}, \quad (3)$$

$$V_{\rm t}(f) = \frac{At_{\rm b}}{j2} \begin{Bmatrix} \mathrm{sinc}[t_{\rm b}(f-f_{\rm c})] \\ -\mathrm{sinc}[t_{\rm b}(f+f_{\rm c})] \end{Bmatrix}, \quad (4)$$

where A is the maximum amplitude, $f_{\rm c}$ is the carrier frequency and $t_{\rm b}$ is the pulse width of waveform.

C. Modulated Gaussian Waveform

The modulated Gaussian transmitted waveform in time domain and its spectral density function are given by

$$v_{\rm t}(t) = Ae^{-(t/d)^2}\sin(2\pi f_{\rm c}t), \quad (5)$$

$$V_{\rm t}(f) = \frac{Ad\sqrt{\pi}}{j2} \begin{bmatrix} e^{-\pi^2 d^2 (f-f_{\rm c})^2} \\ -e^{-\pi^2 d^2 (f+f_{\rm c})^2} \end{bmatrix}, \quad (6)$$

where A is the maximum amplitude of envelope waveform, $f_{\rm c}$ is the carrier frequency and d is the $1/e$ characteristic decay time.

III. Analysis of BER Performance

In this section, the analysis of BER performance is theoretically discussed. The UWB waveform models discussed in Sec. 2 are used as the UWB transmitted waveforms. For UWB free space channel, the complex form of Friis' transmission formula is used [6]-[8]. The transmitting (Tx) and receiving (Rx) antennas are considered to have one constant gains. The frequency transfer function of free space channel $H_{\rm f}$ can be written as

$$H_{\rm f}(f,d) = \frac{c}{4\pi|f|d}e^{-j2\pi fd/c}, \quad (7)$$

where d is the transmitter-receiver (T-R) separation distance and c is the velocity of light. This equation is satisfied for both positive and negative frequencies as it satisfies the causality.

The spectral density of UWB received signal $V_{\rm r}$ is calculated by using multiplication between $H_{\rm f}$ and $V_{\rm t}$, which can be written as

$$V_{\rm r}(f,d) = H_{\rm f}(f,d)\cdot V_{\rm t}(f). \quad (8)$$

This spectral density of UWB received signal includes the distortion effect caused by UWB free space channel.

The matched filter and correlation receivers with frequency transfer functions satisfied constant noise power condition between input and output are considered. For matched filter receiver or optimum correlation receiver, the spectral density of template signal is the complex conjugate of $V_{\rm r}$. The block diagram of matched filter receiver system is shown in Fig. 1. For correlation or transmitted template signal receiver, the spectral density of template signal is the complex conjugate of $V_{\rm t}$. Figure 2 shows the block diagram of correlation receiver system. The receiver gains of both receivers are satisfied the constant noise power condition. Therefore, the frequency transfer functions of matched filter and correlation receivers, ($H_{\rm m}$ and $H_{\rm c}$), can be written as

$$H_{\rm m}(f,d) = \frac{\sqrt{2f_{\rm b}}}{\sqrt{\int_{-\infty}^{\infty}|V_{\rm r}(f,d)|^2df}}V_{\rm r}^*(f,d), \quad (9)$$

$$H_{\rm c}(f,d) = \frac{\sqrt{2f_{\rm b}}}{\sqrt{\int_{-\infty}^{\infty}|V_{\rm t}(f,d)|^2df}}V_{\rm t}^*(f,d), \quad (10)$$

where * is the complex conjugate operator.

The spectral densities of output signal from matched filter and correlation receivers, ($V_{\rm m}$ and $V_{\rm c}$), can be written as

$$V_{\rm m}(f,d) = H_{\rm m}(f,d)\cdot V_{\rm r}(f,d), \quad (11)$$

$$V_{\rm c}(f,d) = H_{\rm c}(f,d)\cdot V_{\rm r}(f,d). \quad (12)$$

The signal-to-noise ratio (SNR) gain of these receivers are defined as the ratio between average power of received signal at receiver input and that at receiver output. The SNR gains of matched filter and correlation receivers, $G_{\rm m}$ and $G_{\rm c}$ can be respectively written as

$$G_{\rm m} = \frac{\int_{-\infty}^{\infty}|V_{\rm m}(f,d)|^2df}{\int_{-\infty}^{\infty}|V_{\rm r}(f,d)|^2df}, \quad (13)$$

$$G_{\rm c} = \frac{\int_{-\infty}^{\infty}|V_{\rm c}(f,d)|^2df}{\int_{-\infty}^{\infty}|V_{\rm r}(f,d)|^2df}. \quad (14)$$

The efficiency of receiver is considered by using correlation coefficient between received and template signals. The correlation coefficients of matched filter and correlation receivers, $C_{\rm m}$

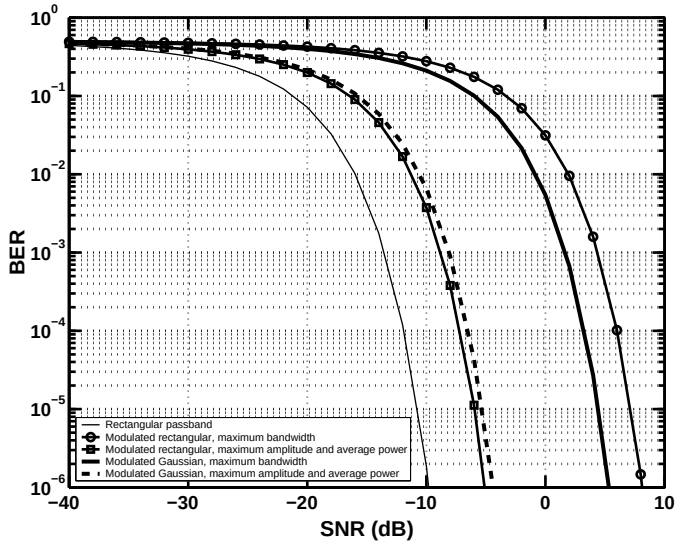

Fig. 3. BER performance of matched filter receiver for UWB waveforms satisfied FCC indoor limit spectral mask.

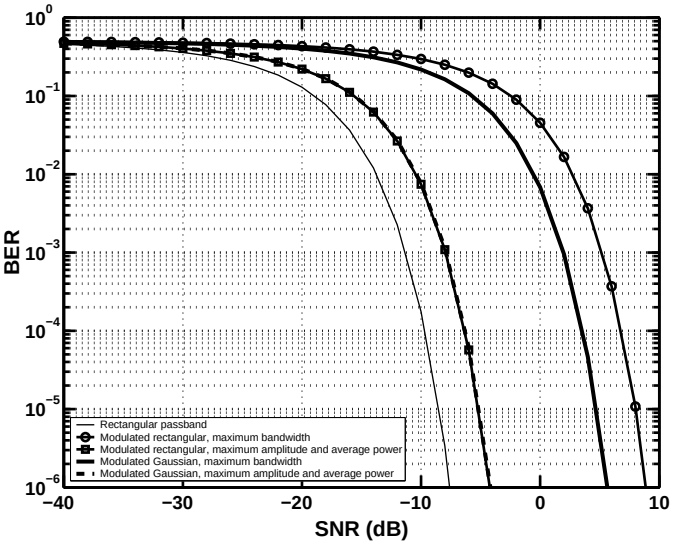

Fig. 4. BER performance of correlation receiver for UWB waveforms satisfied FCC indoor limit spectral mask.

and $C_{\rm c}$ can be respectively written as

$$C_{\rm m} = \frac{\max|\int_{-\infty}^{\infty} V_{\rm m}(f,d)e^{j2\pi ft}df|}{\sqrt{\int_{-\infty}^{\infty}|V_{\rm r}(f,d)|^2df\cdot\int_{-\infty}^{\infty}|H_{\rm m}(f,d)|^2df}}, \quad (15)$$

$$C_{\rm c} = \frac{\max|\int_{-\infty}^{\infty} V_{\rm c}(f,d)e^{j2\pi ft}df|}{\sqrt{\int_{-\infty}^{\infty}|V_{\rm r}(f,d)|^2df\cdot\int_{-\infty}^{\infty}|H_{\rm c}(f,d)|^2df}}, \quad (16)$$

The UWB modulation schemes can be classified in to the antipodal modulation scheme such as binary pulse amplitude modulation (BPAM) and orthogonal modulation scheme such as on-off keying (OOK) and pulse position modulation (PPM) with modulation index of $\delta = 1$ [17]. In this paper, only BER performance of antipodal modulation scheme is considered. For orthogonal modulation scheme, the BER performance can be evaluated in the same way as shown in [15], [18]. The BER performance of matched filter and correlation receivers, $B_{\rm m}$ and $B_{\rm c}$, in additive white Gaussian noise (AWGN) for antipodal modulation scheme can be respectively written as

$$B_{\rm m} = Q\left(\sqrt{\frac{2C_{\rm m}G_{\rm m}f_{\rm b}S}{B_{\rm r}N}}\right), \quad (17)$$

$$B_{\rm c} = Q\left(\sqrt{\frac{2C_{\rm c}G_{\rm c}f_{\rm b}S}{B_{\rm r}N}}\right), \quad (18)$$

where $B_{\rm r}$ is the bit rate, S/N is the SNR at input of receiver and

$$Q(x) = \frac{1}{\sqrt{2\pi}}\int_x^{\infty} e^{-t^2/2}dt, \quad x \geq 0.$$

The SNR is normalized by average power of rectangular passband waveform, which is the theoretical maximum average power of UWB signal, for considering FCC spectral masks. Moreover, the distortion effect caused from UWB channel, occupied bandwidth and bit rate are also included to analyze the BER performance.

IV. Analysis Results

In this section, the analysis results of BER performance are shown. The BER performance of transmitted waveforms, which are the rectangular passband, modulated rectangular and modulated Gaussian waveforms, are analyzed. The T-R separation distance is set to be 10 m, while the bit rate is set to be 110 Mbps. These parameters are based on the IEEE 802.15.3a [19]. The parameters of each waveform, which obtained from the maximum bandwidth, amplitude and average power optimizations satisfied FCC spectral masks for indoor and outdoor limits [15], are used.

Figures 3 and 4 show the BER performances of matched filter and correlation receivers for UWB waveforms satisfied FCC indoor limit spectral mask, respectively. The BER performances of rectangular passband waveforms are lowest for both matched filter and correlation receivers. The BER performances of maximum amplitude and average power optimizations are less than that of maximum bandwidth optimizations. That is because the maximum bandwidth optimizations are much less average power and slightly more bandwidth compared with maximum amplitude and average power optimizations [16]. For comparison between modulated rectangular and Gaussian waveforms, the BER performance of modulated rectangular and Gaussian waveforms with maximum amplitude and average power optimizations are almost the same and are better than the others.

The BER performances of matched filter and correlation receivers for UWB waveforms satisfied FCC outdoor limit spectral mask are shown in Figs. 5 and 6, respectively. The BER performances of rectangular passband waveforms are also lowest for both matched filter and correlation receivers. For

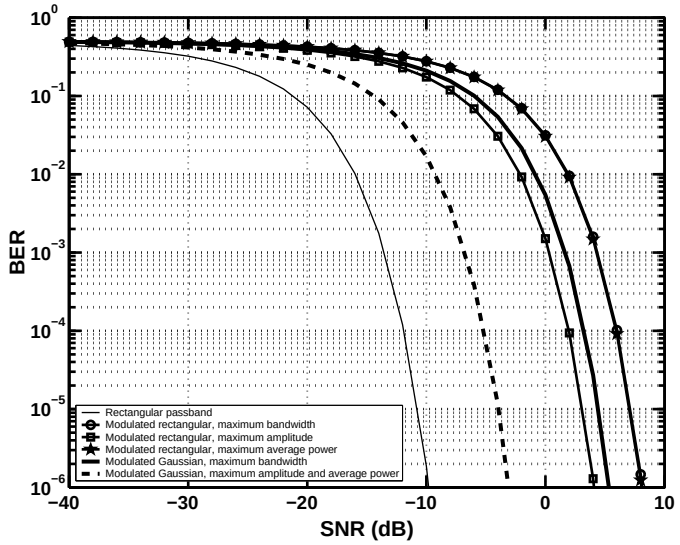

Fig. 5. BER performance of matched filter receiver for UWB waveforms satisfied FCC outdoor limit spectral mask.

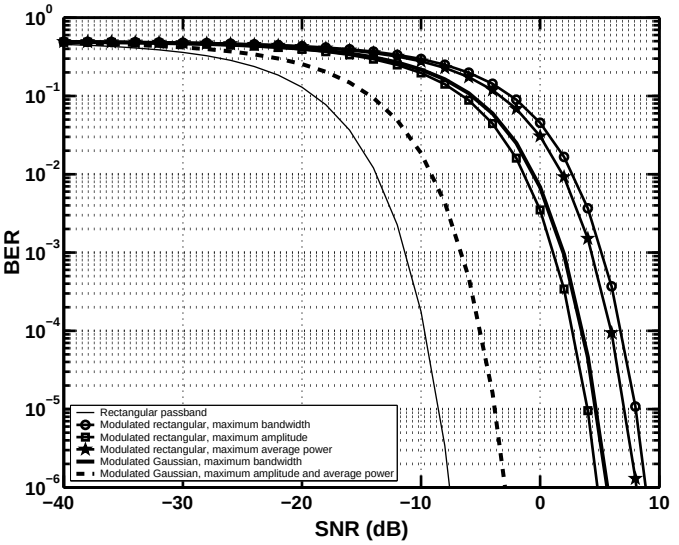

Fig. 6. BER performance of correlation receiver for UWB waveforms satisfied FCC outdoor limit spectral mask.

comparison between modulated rectangular and Gaussian waveforms, the BER performance of modulated Gaussian waveform with maximum amplitude and average power optimizations are clearly better than the others.

V. Conclusion

In this paper, the BER performance of UWB communications with matched filter and correlation receivers are analyzed. The rectangular passband, modulated rectangular and modulated Gaussian waveforms, which is satisfied the UWB signal definition and FCC indoor and outdoor limit spectral masks, are used as the transmitted UWB signal. From the results, the BER performance of rectangular passband waveform with matched filter receiver is the ideal theoretical bound, which is the minimum BER performance case. The modulated rectangular and Gaussian waveforms with maximum amplitude and average power optimizations are appropriate for FCC indoor limit spectral mask, while the modulated Gaussian waveform with maximum amplitude and average power optimizations is appropriate for FCC outdoor limit spectral mask.

***Abstract*— In this paper, a two-dimensional (2-D) transverse magnetic (TM) mode finite difference time domain (FDTD) method is used to simulate the indoor radio wave propagation and model the indoor ultra wideband (UWB) channel. The modulated Gaussian pulse, which is satisfied the UWB signal definition and Federal Communications Commission (FCC) indoor limit spectral mask, is used as the UWB excitation signal. The free space path loss obtained by using FDTD method is shown and verified by comparing with that obtained by using Friis' transmission formula. After that, the path loss in example indoor environment is evaluated. The line-of-sight (LOS) and obstructed (OBS) environments are considered. Furthermore, these obtained data are modeled the path loss by using regression model. The probability density function (PDF) and cumulative distribution function (CDF) of fading are evaluated. The results are discussed in the conclusion.**

I. INTRODUCTION

Recently, ultra wideband (UWB) radio technology has become an important topic for microwave communication because of its low cost and low power consumption potentials [1]. The UWB technology is different from other radio frequency (RF) technologies. Instead of using narrow carrier frequency, the UWB transmits pulses with power spectral density (PSD) in the range of ultra wide frequency spectrum. The Federal Communications Commission (FCC) [2] specified that UWB signal has a frequency spectrum ranging from 3.1 GHz to 10.6 GHz. The FCC defined the UWB signal as those which have a fractional bandwidth equal to or greater than 0.20, or occupied bandwidth equal to or greater than 500 MHz.

The power density of UWB signal is considered to be the noise for other communication systems because its power spectrum is below the FCC part 15 noise limit. The UWB receiver collects the power of received signal to rebuild the pulse. Therefore, the UWB radio technology can coexist with other RF technologies without interference.

The indoor radio communications have become more and more interesting in recent time, which several researchers report the wideband impulse response measurement [3]. Such data is useful to predict the maximum allowable data rates in order to the intersymbol interference and in the exploration of such techniques as diversity and equalization. The effective design, assessment and installation of radio communication in indoor environment require the accurate characterization of radio wave propagation. Therefore, it is also important to consider the propagation behavior in indoor environment.

A ray tracing technique has been demonstrated to be promising for indoor radio propagation [4]. A finite difference time domain (FDTD) method [5], [6] is the alternative method for modeling channel. Although the FDTD method requires more computer resources compared with the ray tracing technique, the simulation of indoor environment requires the computer resources less than that of outdoor environment. Furthermore, the FDTD method can be calculated the scattered fields more accurately compared with ray tracing technique for complex lossy structures with finite dimensions encountered in indoor environment. Therefore, the FDTD method is usually used to model the narrow band channel [7], [8]. For UWB communications, there are many researches that used the FDTD method to model the channel [9], [10]. However, there is no consideration about path loss model with FCC regulation of UWB signal.

In this paper, the two-dimensional (2-D) transverse magnetic (TM) mode FDTD method, which is satisfied the numerical stability condition [11] and with perfectly matched layer absorbing boundary condition (PML ABC) [12], is used to simulate the indoor radio wave propagation and model the indoor UWB channel. The modulated Gaussian pulse, which is satisfied the UWB signal definition and FCC indoor limit spectral mask [13], is used as the UWB excitation signal. The free space path loss obtained by using FDTD method is shown and verified by comparing with that obtained by using Friis' transmission formula [14]. which has the high accuracy for UWB channel [15]. After that, the path loss in example indoor environment is evaluated. The line-of-sight (LOS) and obstructed (OBS) environments are considered. Furthermore, these obtained data are modeled the path loss by using regression model. The probability density function (PDF) and cumulative distribution function (CDF) of fading are evaluated.

II. FDTD METHODS

The 2-D TM mode finite difference equations are directly derived from Maxwell's curl equations in time domain. To obtain discrete approximation of continuous partial differential equations, the centered difference approximation is used on both time and space first-order partial difference. The entire computation domain is the collection of all the unit cells. The dimensions of unit cell along x and y directions are Δx and Δy, respectively. The node with subscript indices i and j corresponds to the node number in x and y directions. The time step is indicated with the superscript index n. The time interval of each time step is Δt. After simple arrangement, the 2-D TM mode finite difference equations are described as [5],[6]

$$H_x|_{i,j}^{n+\frac{1}{2}} = H_x|_{i,j}^{n-1/2} + \left(\frac{\Delta t}{\mu_{i,j}}\right)\left(\frac{E_z|_{i,j-\frac{1}{2}}^{n} - E_z|_{i,j+\frac{1}{2}}^{n}}{\Delta y}\right), \quad (1)$$

$$H_y|_{i,j}^{n+\frac{1}{2}} = H_y|_{i,j}^{n-1/2} + \left(\frac{\Delta t}{\mu_{i,j}}\right)\left(\frac{E_z|_{i+\frac{1}{2},j}^{n} - E_z|_{i-\frac{1}{2},j}^{n}}{\Delta x}\right), \quad (2)$$

$$E_z|_{i,j}^{n+1} = C_{\mathrm{a}}|_{i,j} E_z|_{i,j}^{n-1} + C_{\mathrm{b}}|_{i,j}\left(\frac{H_y|_{i+\frac{1}{2},j}^{n+\frac{1}{2}} - H_y|_{i-\frac{1}{2},j}^{n+\frac{1}{2}}}{\Delta x} + \frac{H_x|_{i,j-\frac{1}{2}}^{n+\frac{1}{2}} - H_x|_{i,j+\frac{1}{2}}^{n+\frac{1}{2}}}{\Delta y}\right), \quad (3)$$

with the electric field updating coefficients at node (i, j) are given by

$$C_{\mathrm{a}}|_{i,j} = \left(1 - \frac{\sigma_{i,j}\Delta t}{2\varepsilon_{i,j}}\right) \Big/ \left(1 + \frac{\sigma_{i,j}\Delta t}{2\varepsilon_{i,j}}\right), \quad (4)$$

$$C_{\mathrm{b}}|_{i,j} = \left(\frac{\Delta t}{\varepsilon_{i,j}}\right) \Big/ \left(1 + \frac{\sigma_{i,j}\Delta t}{2\varepsilon_{i,j}}\right), \quad (5)$$

where H is the magnetic field, E is the electric field, μ is the magnetic permeability, ε is the electric permittivity and σ is the electric conductivity. The maximum time step is limited by stability restriction of finite difference equation [11].

The modulated Gaussian pulse, which is satisfied the UWB signal definition and FCC indoor limit spectral mask, is used as the UWB excitation signal V_{S}. The expression of this pulse is [7]

$$V_{\mathrm{S}}|^{n} = Ae^{-[(n-n_0)\Delta t/d]^2}\sin[2\pi f_{\mathrm{c}}(n-n_0)\Delta t], \quad (6)$$

where A is the maximum amplitude of envelope signal, f_{c} is the carrier frequency, d is the $1/e$ characteristic decay time and n_0 is the delayed time step.

The tangential field components on four mesh walls must be specified in such a way that outgoing waves are not reflected. The FDTD simulation in this paper uses the PML ABC [12].

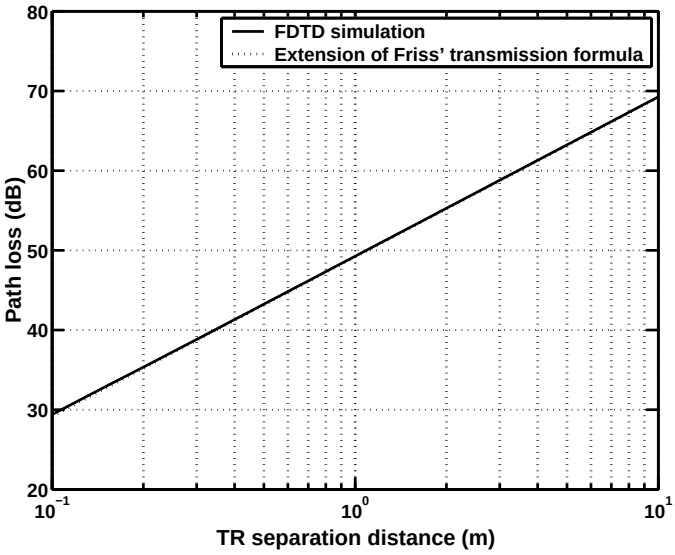

Fig. 1. Free space path loss obtained from FDTD simulation compared with that obtained from Friis' transmission formula.

TABLE I
ELECTROMAGNETIC PROPERTIES OF DIFFERENT MATERIALS.

Material	Electromagnetic property

Dry concrete wall	$\varepsilon_{\mathrm{r}} = 5.00$, $\sigma = 0.70$

III. UWB CHANNEL MODEL

In this section, the path loss obtained from FDTD method is modeled. First, the 2-D TM FDTD simulation is done in the free space environment. The cell sizes in x and y directions are $\Delta x = \Delta y = 0.005$ m. The PML ABC with 16 layers is used to reduce the reflection error at edges. The time interval of each time step is $\Delta t = 11.79$ ps, which is satisfied the numerical stability condition. For UWB excitation signal, the parameters of modulated Gaussian signal, which is satisfied the UWB signal definition and indoor limit spectral mask, are $f_{\mathrm{c}} = 7.34$ GHz, $d = 0.11$ ns and $A = 0.27$ V. These signal parameters are the maximum amplitude and average power optimizations with bit rate of 100 Mbps [13].

Figure 1 shows the free space path loss obtained from FDTD simulation compared with that obtained from Friis' transmission formula along transmitter-receiver (TR) separation distance 0.1 to 10 m. From the figure, the path loss obtained from FDTD simulation coincides very well with that obtained from Friis' transmission formula. There is root mean square (RMS) error only 0.13 dB. This verifies that FDTD simulation can be modeled the path loss of UWB channel.

Subsequently, the FDTD simulation is done in the room structure with excitation signal located at point S. The dimension of this room is shown in Fig. 2. The room consists of gypsum board, plywood door, metallic cabinet, brick and dry concrete walls. The metallic cabinet is assumed to be the perfect

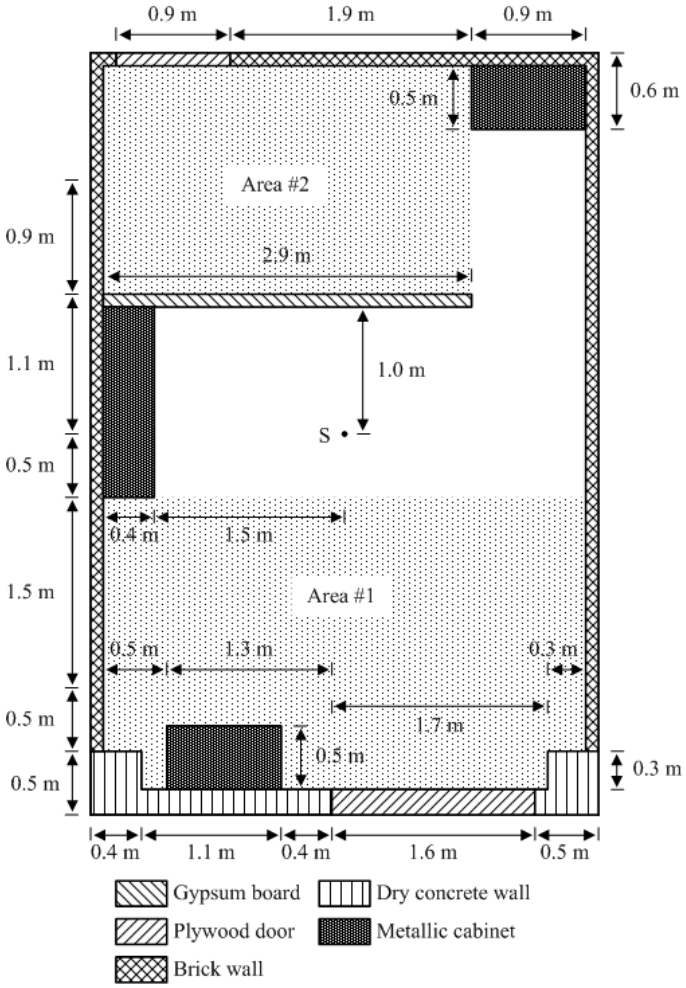

Fig. 2. Layout of room environment.

conductor. The electromagnetic properties of other materials are listed in Table 1 [4]. The two areas, Area #1 and Area #2, as shown in Fig. 2 are considered for LOS and OBS environments, respectively. The UWB path loss of both considered areas in dB at note (i, j) can be evaluated by using

$$PL|_{i,j} = 10 \log \left[\frac{\sum_n (V_{\mathrm{S}}|^n)^2}{\sum_n \left(V_{\mathrm{R}}|^n_{i,j}\right)^2} \right], \tag{7}$$

where V_{R} is the received signal.

The TR separation distance d at node (i, j) is computed by using

$$d = \sqrt{[(i - i_{\mathrm{S}})\Delta x]^2 + [(j - j_{\mathrm{S}})\Delta y]^2}, \tag{8}$$

where $(i_{\mathrm{S}}, j_{\mathrm{S}})$ is the node of UWB excitation signal.

For modeling path loss, the linear regression model based on log-distance path loss model [16] is used. The model can be realized by curve fitting on a scatter plot of obtained path loss and then derived the path loss exponent n from

$$PL(d) = \overline{PL}(1) + 10n \log(d) + X_\sigma, \tag{9}$$

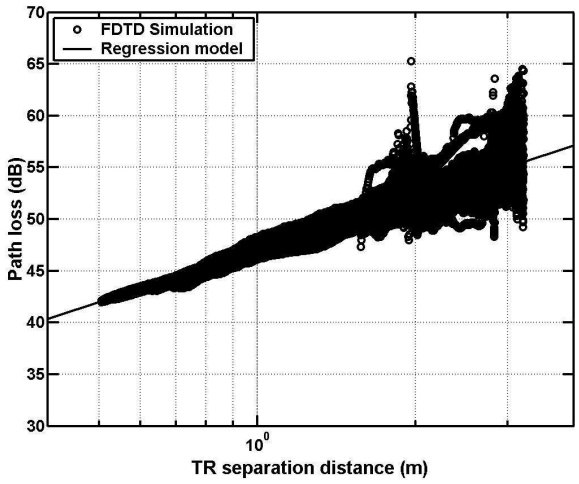

Fig. 3. Scatter plot of path loss obtained from FDTD simulation and regression model in Area #1.

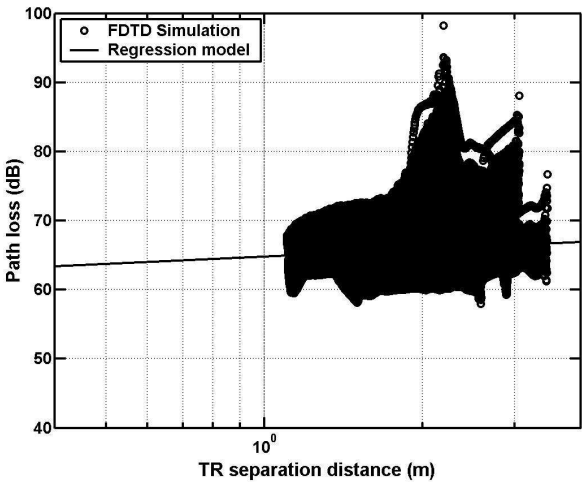

Fig. 4. Scatter plot of the path loss obtained from FDTD simulation and regression model in Area #2.

where $PL(d)$ is the path loss in dB at TR separation distance of d (m), $\overline{PL}(1)$ is the average large-scale path loss at TR separation distance is 1 m, X_σ is the fading parameter with standard deviation of σ in dB. When plotted on a log-distance graph, the path loss model is a straight line and n can be determined from the slope of $10n$ dB per decade. The value n and σ depend on the specific propagation environment. The main objective of this simulation is to determine $\overline{PL}(1)$, n and X_σ of UWB signal propagation in Area #1 and Area #2.

Figure 3 shows the scatter plot of path loss obtained from FDTD simulation and regression model in Area #1, which is the LOS environment. The 323,081 data are used to model the path loss. For this area, the model parameters are $\overline{PL}(1) = 47.00$ dB and $n = 1.68$. The scatter plot of path loss obtained from FDTD simulation and regression model in Area #2, which is the OBS environment, is shown in Fig. 4. The 207,861 data are

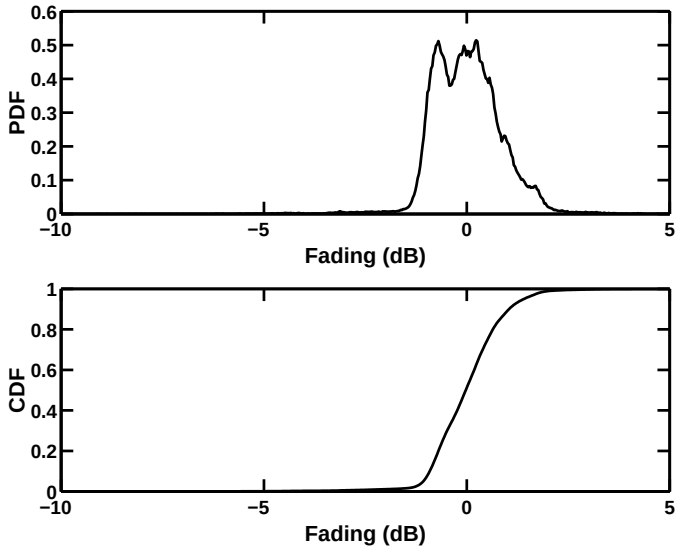

Fig. 5. PDF and CDF of fading in Area #1.

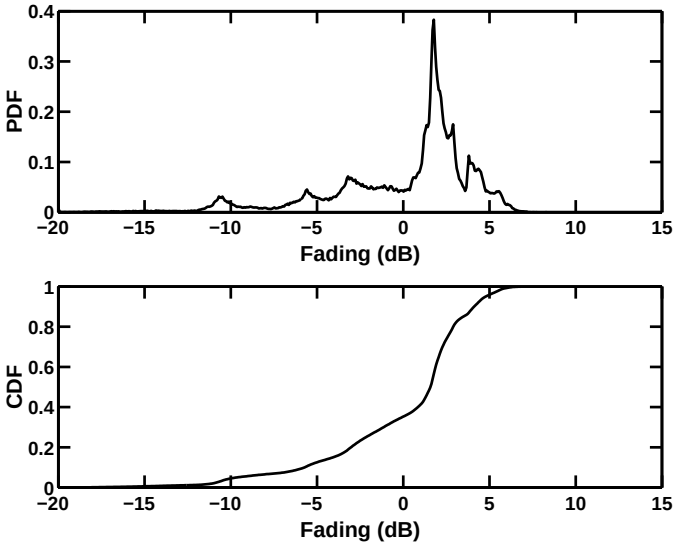

Fig. 6. PDF and CDF of fading in Area #2.

used to model the path loss. For this area, the model parameters are $\overline{PL}(1) = 64.79$ dB and $n = 0.35$.

For considering the fading parameter X_σ, the statistic model is used. The PDF and CDF of fading are evaluated. Figure 5 shows the PDF and CDF of fading in Area #1. The statistic parameters of this area are the standard deviation of $\sigma = 0.86$ dB and zero mean. The PDF and CDF of fading in Area #2 are shown in Fig. 6. The statistic parameters of this area are the standard deviation of $\sigma = 4.21$ dB and zero mean. We can see that the fading in Area #2, which is OBS environment, is more fluctuate than that in Area #1, which is LOS environment.

IV. Conclusion

In this paper, the 2-D TM mode FDTD method is used to simulate the indoor radio wave propagation and model the path loss of UWB channel. The free space path loss obtained by FDTD method is verified with that obtain by Friis' transmission formula. By using FDTD method, the numerous data can be obtained for modeling indoor UWB channel. It is flexible to model the different environment according to desire accuracy by setting cell size. This simulation can be applied to arbitrary bandwidths or types of UWB signals. In order to develop a reliable UWB product for WPAN applications, a good understand of UWB channel model of specific environment is essential for link budget. Therefore, FDTD method provides a high flexible and convenient tool for modeling UWB channel.

***Abstract*— According to satisfy the Federal Communications Commission (FCC) indoor and outdoor limit spectral masks, a good understanding of power spectral density (PSD) of ultra wideband (UWB) signal and how it is influenced by modulation without and with time hoping (TH) is necessary. In this paper, the PSD of UWB signal using pulse shape modulation (PSM) without and with TH is analyzed. The orthogonal pair of modulated Gaussian waveforms, which satisfied the UWB signal definition and FCC indoor and outdoor limit spectral masks, are considered. The PSD of UWB signal is analyzed and shown. The results are discussed in the conclusion.**

I. Introduction

Almost all communication systems employ the sinusoidal signal as a transmitted waveform. Its information is mapped via the modulation. The result is that the power spectral density (PSD) of this signal is well concentrated in specific frequency band. It easily suppresses noise and interference by using bandpass filter. Unfortunately, the narrowband system is sensitive to fading. Furthermore, frequency spectrum is divided into many narrow frequency bands causing deficient spectrum for new communication system.

An ultra wideband (UWB) refers to a technology, which makes the use of a signal waveform occupied a very large bandwidth. The Federal Communications Commission (FCC) in US defines the UWB signal, which is any signal where the fractional bandwidth is equal to or greater than 0.20, or the occupied bandwidth is equal to or greater than 0.50 GHz. The fractional and occupied bandwidth are defined as [1]

$$\text{Fractional bandwidth} = \frac{2(f_{\mathrm{H}} - f_{\mathrm{L}})}{f_{\mathrm{H}} + f_{\mathrm{L}}}, \quad (1)$$

$$\text{Occupied bandwidth} = f_{\mathrm{H}} - f_{\mathrm{L}}, \quad (2)$$

where f_{L} and f_{H} are the lowest and highest frequencies at the -10 dB point, respectively.

The main concern about UWB communications is that they occupy a portion of spectrum where other narrowband communications already operate, so a regulation is necessary in order to avoid co-existence interference problems. Therefore, the FCC regulates the indoor and outdoor spectral masks to limit the maximum emission of unlicensed UWB signals for guaranteeing the protection to the already existent and planed radio services. The UWB communications specified FCC indoor and outdoor spectral masks are undetectable by other communication systems and having the PSD below past 15 noise limit. Furthermore, the UWB radio technology is an ideal candidate that can be utilized for commercial, short-range, low power, low cost, indoor and outdoor communication systems such as wireless personal area networks (WPANs) [2]-[5].

Numerous UWB waveforms have been proposed [6]. The waveform designs are reviewed, but no considered about the UWB signal definition and spectral masks specified by FCC. The signal processing and numerical techniques are used to design the UWB waveform [7]-[14]. Although the waveform has very high effective spectral in designed frequency range, these algorithms are complex. Therefore, the simple waveforms for UWB communications are proposed [15]. After that, the orthogonal pairs of simple UWB waveforms are developed for pulse shape modulation (PSM) scheme [16]. Although, these waveforms have the closed form expressions in both time and frequency domains, they are considered only the PSD of one UWB waveform. There is no consideration about the PSD of pulse train of UWB signal using modulation scheme.

In this paper, the PSD of UWB signal using modulation scheme is analyzed. The modulation scheme is focused on the PSM without and with time hoping (TH) [17]. The orthogonal pair of modulated Gaussian waveforms, which satisfied the UWB signal definition and FCC indoor and outdoor limit spectral masks [16], are considered. The PSD of UWB signal consists of the continuous and discrete components. The discrete component presents greater interference to narrowband communication system than the continuous component. The PSD of UWB signal using PSM without and with TH is analyzed and shown. The capability of PSM with TH that suppressed the discrete component is discussed in the conclusion.

This paper is organized as follows. Section 2, the PSD of UWB signal using PSM is briefly described. Next, the PSD analysis results are demonstrated in Sec. 3. Finally, the conclusions are drawn in Sec. 4.

II. PSD OF UWB SIGNAL USING PSM

In this section, we will first introduce the UWB waveform model. After that, we will investigate the PSD of UWB signal using PSM without and with TH.

1) UWB Waveform Model: The UWB waveforms that used for PSM scheme are the orthogonal pair of modulated Gaussian waveforms. The orthogonal pair of modulated Gaussian waveforms in time domain, f_1 and f_2, and their spectral density functions, F_1 and F_2, are given by [16]

$$f_0(t) = A_0 e^{-(t/d)^2} \sin(2\pi f_c t), \quad (3)$$

$$f_1(t) = A_1 e^{-(t/d)^2} \cos(2\pi f_c t), \quad (4)$$

$$F_0(f) = \frac{A_0 d\sqrt{\pi}}{j2} \begin{bmatrix} e^{-\pi^2 d^2 (f-f_c)^2} \\ -e^{-\pi^2 d^2 (f+f_c)^2} \end{bmatrix}, \quad (5)$$

$$F_1(f) = \frac{A_1 d\sqrt{\pi}}{2} \begin{bmatrix} e^{-\pi^2 d^2 (f-f_c)^2} \\ +e^{-\pi^2 d^2 (f+f_c)^2} \end{bmatrix}, \quad (6)$$

where f_c is the carrier frequency, d is the $1/e$ characteristic decay time, A_0 and A_1 are the maximum amplitudes of waveform envelopes f_0 and f_1, respectively.

2) PSD of UWB Signal Using PSM without TH: The PSM without TH uses the orthogonal pair of waveforms to represent the bits '0' and '1'. The UWB signal using PSM without TH can be presented as

$$s(t) = \sum_{n=-\infty}^{\infty} \left[(1-d_n) f_0(t - nT_s) + d_n f_1(t - nT_s) \right], \quad (7)$$

where d_n is the digital data in sequence of n, T_s is the time interval of bit data, f_0 and f_1 are the waveforms representing bits '0' and '1', respectively.

The probability distribution function (PDF) of d_n is

$$P\{d_n\} = \begin{cases} p & d_n = 1 \\ 1-p & d_n = 0 \end{cases}, \quad (8)$$

where p is the probability of d_n is the bit '1'.

For considering radiated PSD, the transmitter (Tx) antenna is assumed to be the isotropic antenna. The internal circuit and Tx antenna impedances are assumed to be the same real value R. That is the ideal with maximum radiated PSD. In this paper, the path loss and measurement system are not considered. Therefore, the radiated PSD of UWB signal using PSM without TH can be derived as

$$S_R(f) = \lim_{N\to\infty} \frac{1}{4RNT_s} \left| \sum_{n=-N/2}^{N/2} \begin{bmatrix} (1-d_n)F_0(f) \\ +d_n F_1(f) \end{bmatrix} e^{-j2n\pi f T_s} \right|^2. \quad (9)$$

3) PSD of UWB Signal Using PSM with TH: The PSM with TH is used to suppress the discrete component of PSD. The UWB signal using PSM with TH can be presented as

$$s(t) = \sum_{n=-\infty}^{\infty} \begin{Bmatrix} (1-d_n) f_0(t - nT_s - T_n) \\ +d_n f_1(t - nT_s - T_n) \end{Bmatrix}, \quad (10)$$

where T_n is the TH.

The PDF of T_n is the uniform distribution in the range of $-T_s/2$ to $T_s/2$, which can be written as

$$P\{T_n\} = \begin{cases} \frac{1}{T_s} & -\frac{T_s}{2} \le T_n \le \frac{T_s}{2} \\ 0 & \text{elsewhere} \end{cases}. \quad (11)$$

The radiated PSD of UWB signal using PSM with TH is considered in the same way of that without TH, which can be derived as

$$S_R(f) = \lim_{N\to\infty} \frac{1}{4RNT_s} \left| \sum_{n=-N/2}^{N/2} \begin{matrix} \{(1-d_n)F_0(f) \\ +d_n F_1(f)\} e^{-j2\pi f(nT_s+T_n)} \end{matrix} \right|^2. \quad (12)$$

III. PSD ANALYSIS RESULTS

The orthogonal pair of modulated Gaussian waveforms is used as the UWB signal for representing bits '0' and '1'. The waveform parameters, which obtained from the maximum amplitude and average power optimizations [16], are considered for both FCC indoor and outdoor limit spectral masks. The parameters R and N are set to be $50\ \Omega$ and $1,000$ bits, respectively. The bit rate is assumed to be 110 Mbps, therefore T_s is equal to 9.09 ns. For FCC indoor limit spectral mask, the waveform parameters are $A_0 = A_1 = 3.76$ V, $d = 0.11$ ns and $f_c = 7.34$ GHz. The time domain waveforms and their PSD compared with FCC indoor limit spectral mask are shown in Fig. 1. For FCC outdoor limit spectral mask, the waveform parameters are $A_0 = A_1 = 3.18$ V, $d = 0.13$ ns and $f_c = 6.85$ GHz. Figure 2 shows the time domain waveforms and their PSD compared with FCC outdoor limit spectral mask. The PSD of each waveform is the same with another for both cases.

For analyzing PSD of UWB signal using PSM without and with TH, two cases of p are considered for FCC indoor and outdoor limit spectral masks. For the first case, the parameter p is set to be 0.0 or 1.0, which all bits are '0' or '1'. Another case, the parameter p is set to be 0.5, which the bits '0' and '1' are equal.

Figures 3 and 4 show the PSD of UWB signal using PSM without TH compared with FCC indoor and outdoor limit spectral masks, respectively. The continuous and discrete component characteristics of PSD for FCC indoor and outdoor limit spectral masks are the same. The PSD of $p = 0.0$ or 1.0 is more than the FCC indoor and outdoor limit spectral masks up to 29.99 dB, while that of $p = 0.5$ is more than the FCC indoor and outdoor limit spectral masks up to 26.98 dB. That because the discrete component of $p = 0.5$ is less than that of $p = 0.0$

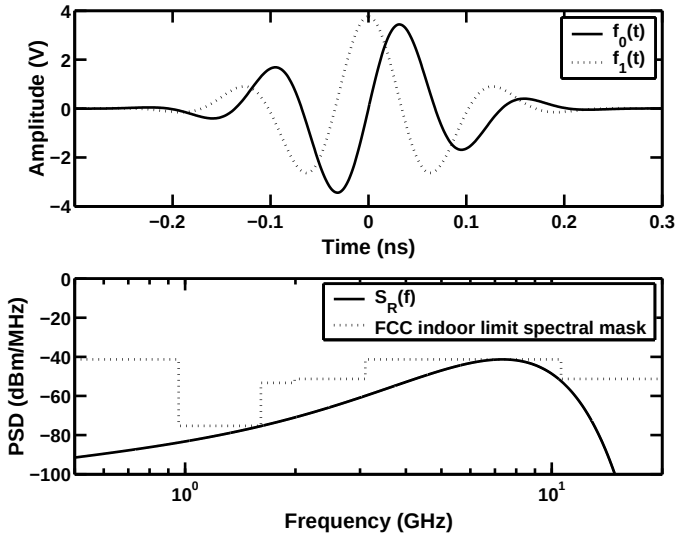

Fig. 1. Time domain waveforms and their PSD compared with FCC indoor limit spectral mask.

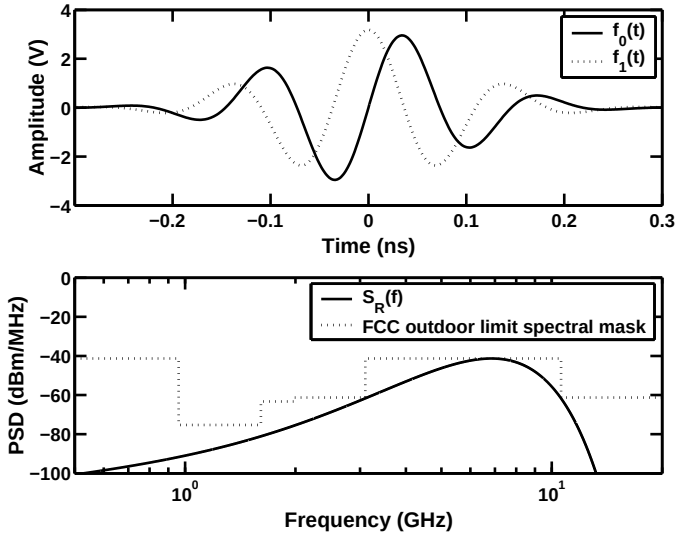

Fig. 2. Time domain waveforms and their PSD compared with FCC outdoor limit spectral mask.

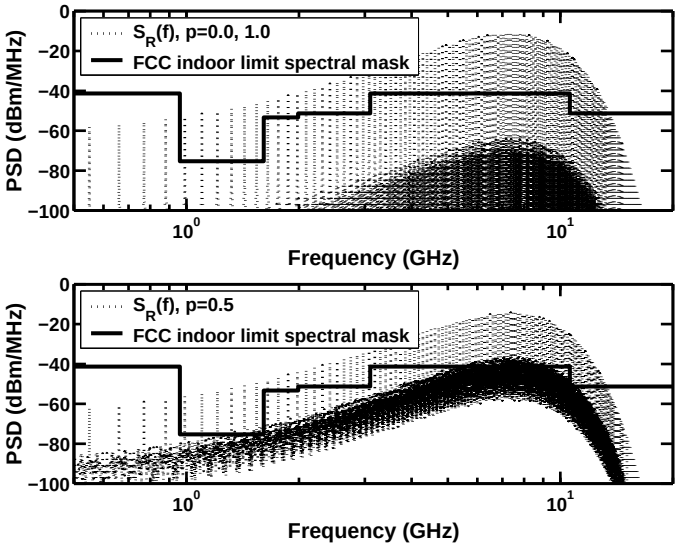

Fig. 3. PSD of UWB signal using PSM without TH compared with FCC indoor limit spectral mask.

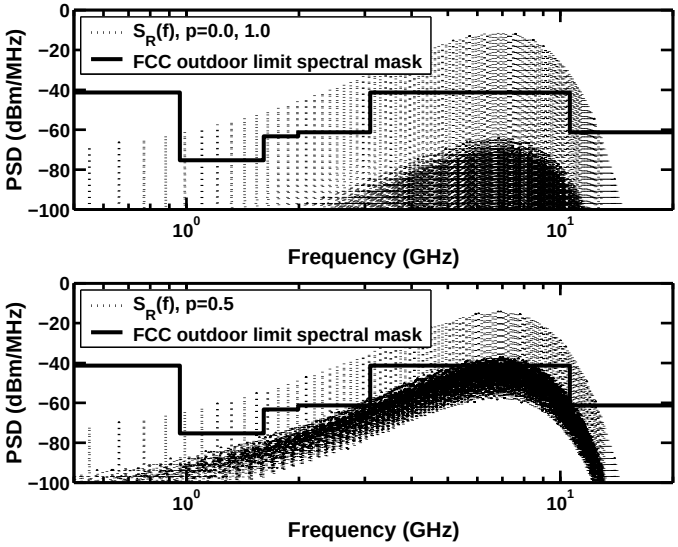

Fig. 4. PSD of UWB signal using PSM without TH compared with FCC outdoor limit spectral mask.

or 1.0. Therefore, the PSD of $p = 0.5$ is decreased from that of $p = 0.0$ or 1.0 about 3 dB. Although this orthogonal pair of modulated Gaussian waveforms is well designed to satisfy the FCC indoor and outdoor limit spectral masks, their PSD using PSM without TH exceeds the FCC indoor and outdoor limit spectral masks very much. Then, the technique that uses to suppress the discrete component of PSD is necessary.

In this paper, the PSD of UWB signal using PSM with TH is considered to suppress the discrete component. The PSD of UWB signal using PSM with TH compared with FCC indoor and outdoor limit spectral masks are shown in Figs. 5 and 6, respectively. The continuous and discrete component characteristics of PSD for FCC indoor and outdoor limit spectral masks are little difference. For FCC indoor limit spectral mask, the PSD of $p = 0.0$ or 1.0 is more than the FCC indoor limit spectral mask up to 8.07 dB, while that of $p = 0.5$ is more than the FCC indoor limit spectral mask up to 7.73 dB. For FCC outdoor limit spectral mask, the PSD of $p = 0.0$ or 1.0 is more than the FCC indoor limit spectral mask up to 8.37 dB, while that of $p = 0.5$ is more than the FCC indoor limit spectral mask up to 8.32 dB. The PSD of $p = 0.5$ is decreased from that of $p = 0.0$ or 1.0 about 0.34 and 0.05 dB for FCC indoor and outdoor limit spectral masks, respectively. The discrete component of UWB signal using PSM with TH is less than that of without TH about 22 dB for $p = 0.0$ or 1.0, and 19 dB for $p = 0.5$. Although the PSD of UWB signal using PSM with TH is extremely reduced compared with that of without

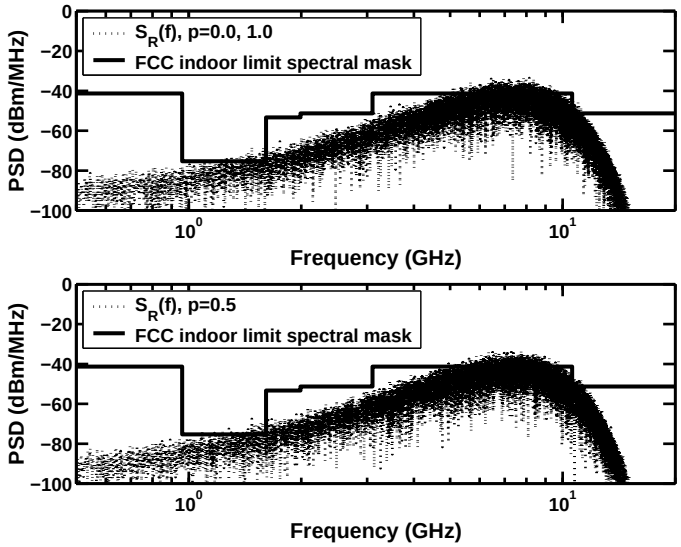

Fig. 5. PSD of UWB signal using PSM with TH compared with FCC indoor limit spectral mask.

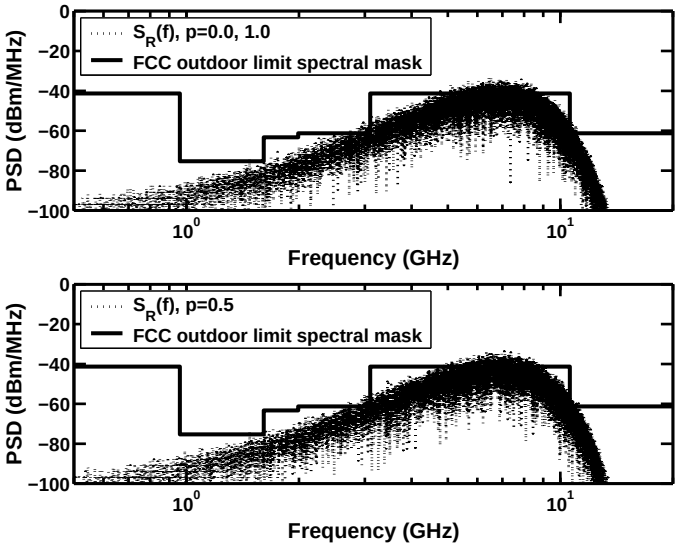

Fig. 6. PSD of UWB signal using PSM with TH compare with FCC outdoor limit spectral mask.

TH, their PSD still exceeds the FCC indoor and outdoor limit spectral masks. Therefore, the peak power of UWB signal must decreases to satisfy the FCC indoor and outdoor limit spectral masks.

IV. Conclusion

In this paper, the PSD of UWB signal using PSM without and with TH is analyzed. The orthogonal pair of modulated Gaussian waveforms, which satisfied the UWB signal definition and FCC indoor and outdoor limit spectral masks, are considered. From the results, we can see that the PSD characteristics of UWB signal for FCC indoor and outdoor limit spectral masks are almost the same. The PSM with TH can be suppressed the discrete component of the PSD about 20 dB. But this is not sufficient. The peak power of UWB signal must decreases about 9 dB to satisfy the FCC indoor and outdoor limit spectral masks.

***Abstract*— The performance investigation of wireless communication system based on the realistic indoor channels are necessary to design the receiver. In this paper, the performance of 2 ultra wideband (UWB) Rake receivers for realistic indoor channels are proposed. The UWB Rake receivers with minimum mean square error (MMSE) and least square (LS) channel estimators are compared. By using the channel impulse response between human body shadowing and Saleh-Valenzuela (S-V) realistic indoor channel model are combined. As the simulation results, the performance of Rake receiver with the MMSE channel estimator is better than with the LS channel estimator for all UWB indoor channels. Therefore, the MMSE channel estimator can be used for the UWB Rake receiver in the realistic indoor environment.**

I. INTRODUCTION

Ultra-wideband technology is an attractive candidate for short-range wireless communication. The definition of the Federal Communications Commission (FCC)was formulated the emission limits for UWB of effective isotropic radiated power (EIRP) below -41.3 dBm/MHz, low power consumption, low cost structure and the frequency range of 3.1$\sim$10.6 GHz [1]. The UWB communication system has high bandwidth and high data rate support. Therefore, the UWB is provided to wireless personal area network (WPAN) and applied to use in home environment or office area. For UWB system, the data are transmitted using nano-second baseband pulses and without the need for mixers. Since finding time resolution for accurate ranging or positioning is easier than narrowband, EIRP has very low power, intersymbol interference (ISI) simply occurred for high data rate. Consequently, Rake receiver is suitable for this system. The Rake receiver is used for CDMA technology and wideband technology. Because the structure of Rake receiver can separate multi-path for adjusting the received signal to increase SNR level and purge ISI on the received signal.

The channel estimator is very important for Rake receiver. Because it estimates the amplitude or gain of the received signal and the results of the gain combining of signal is followed by it and the number of signal are arrived. The important parameters for channel estimation are PDF of channel impulse response (CIR), noise variance and number of pilot signals per data range (for data aided). Therefore, the performances of UWB Rake receiver based on the different complexity of the estimation parameters are investigated.

The S-V channel model of UWB communication is proposed for the multi-path channel in indoor environment. This model is dived into 4 groups of environments, namely, CM1-CM4. CM1 describes a line-of-sight (LOS) scenario with distance between transmitter and receiver of less than 4 meters. CM2 describes the same range but for a non-LOS situation. CM3 represents a non-LOS scenario for distances between TX and RX of 4-10 meters. Finally, CM4 describes an environment with strong delay dispersion, resulting in a delay spread of 25 ns. For CM1-CM4, the models did not fix the environment location, because the models are adjusted for universal stochastic model of the wireless propagation channel and can be developed for analyzing the UWB communication system. On the other hand, the human body may obstruct the propagated signal between TX and RX. Therefore, the effects of human body shadowing are important issue for designing UWB receiver in realistic environment.

Several literatures have studied the performance of UWB Rake reception for indoor channel [2]-[4]. These investigations do not consider the human body shadowing effects. However, the performance of UWB communication in the realistic environment is still necessary for designing the receiver, especially when propagated signal is shadowed by the human body. Therefore, in this paper, the combining of channel impulse responses between the human body shadowing and the S-V multi-path indoor channel are investigated.

The rest of the paper is organized as follows: Section II presents the transmitter signal model, S-V channel models, measurement channel impulse response, and Rake receiver models. Section III summarizes the performance results of the realistic indoor channel and Section IV is conclusion.

II. SYSTEM MODEL

For the UWB system, transmitted signal has a very small pulse width and no carrier frequency. The indoor CIR of the human body shadowing are very important issue in the wireless personal area network (WPAN) communication. And the UWB Rake receiver with MMSE and LS channel estimators are presented.

A. Transmitter Signal Model

The characteristic of Gaussian doublet waveform is almost uniformly distributed on frequency spectrum of UWB technology. Specifically, the second derivative of the Gaussian pulse is chosen for non carrier modulation of the UWB signal and

then it is given by [5]-[7]

$$p(t) = \sqrt{E_p}\sqrt{\frac{8}{3\tau}}\left(1 - 4\pi\left(\frac{t - T_c}{\tau}\right)^2\right) e^{-2\pi\left(\frac{t-T_c}{\tau}\right)^2}, \quad (1)$$

where E_p is energy of signal, τ is time scaling factor by set to 0.2877 ns, T_c is time chip of next bit. In this time, the Bi-Phase Modulation (BPM) has been experimented and expressed as

$$s(t) = \sum_{i=-\infty}^{\infty} b_i p(t - iT_s), \quad (2)$$

where $p(t)$ is the Gaussian doublet waveform, $b_i \in \{-1, +1\}$ are bi-phase modulation symbols, i is bit number, T_s is bit duration.

B. Channel Model

Nowadays, there are several channel models which are used for analyzing wireless communication system. Each model is designed suitable for specific situation such as indoor and outdoor environment. However, there is no model which combines the effects of channel impulse responses with the human body effects. Thus, in the paper, the combination of the human body shadowing effects based on measurement channels in [8]-[9] and the realistic S-V channel model is considered.

The realistic channel for IEEE 802.15 study group 3a has been developed by Saleh-Valenzuela (S-V model) and proposed for the real indoor channel model, where the clusters and rays are multi-path components [10]. This multi-path channel can be expressed as

$$h(t) = \sum_{l=0}^{L}\sum_{k=0}^{K} \alpha_{k,l}\delta(t - T_l - \tau_{k,l}), \quad (3)$$

where the real value of multi-path gain is defined by $\alpha_{k,l}$ for cluster l and ray k. The lth cluster arrives at T_l and its kth ray arrives at $\tau_{k,l}$ which is relative to the first path in cluster l. However, the multi-path channels consist of four different models, namely, CM1, CM2, CM3 and CM4. The detail of the four different groups is provided in [11]. The CIR of the human body channel is derived as in the S-V model except the clusters of arrivals.

The combination of 2 CIRs between the S-V multi-path indoor channel models (in each CM groups indoor channel) and the human body shadowing are summarized for each CIRs or described by $h_{com} = h_{sv} + h_{human}$, where h_{sv} is the CIR of S-V model and h_{human} is the CIR of the human body shadowing. Fig. 1 shows are example of the CIR of S-V model for CM4, the CIR of the human body shadowing from measured channel [12] and the combining of 2 CIRs between the S-V model and the human body shadowing, respectively.

C. Rake Receiver Model

In ideal Rake receiver, the number of multi-paths per bit duration is combined as time and amplitude arrivals. Therefore, the SNR of Rake receiver is higher than conventional receiver. In this investigation, the Rake receiver based on MRC

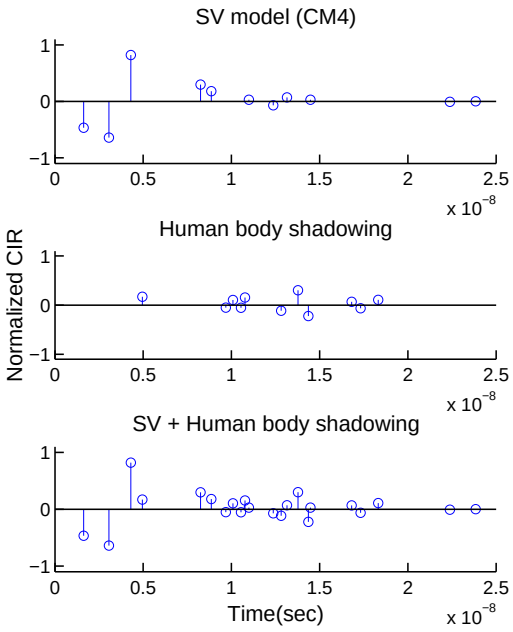

Fig. 1. The CIR of the S-V model for CM4, the human body shadowing from measured channel, and the combining of the S-V model and the human body shadowing, respectively.

combining is employed. The received signal for UWB BPM transmitter can be expressed as

$$r(t) = \sum_{i=-\infty}^{\infty} b_i \sum_{l=0}^{L-1} \alpha_l p(t - \tau_l - iT_s) + n_0(t), \quad (4)$$

where α_l is channel impulse response with multi-path component, τ_l is chip arrival times and n_0 is AWGN noise with two side spectra density of $N_0/2$.

In the case of no ISI and when the noise is AWGN, the optimal receiver is a filter matched to the received waveform. Typically, this is implemented in Rake receiver structure with M fingers, which can be represented as the filter with response given by

$$f(t) = \sum_{m=0}^{M-1} \beta_m p(-t - \theta_m), \quad (5)$$

where the Rake delays are θ_m. The sampled output of the Rake receiver is then

$$\begin{aligned} y_n &= [r(t) * f(t)]|_{t=nT} \\ &= \sum_{i=-\infty}^{\infty} b_i \sum_{l=0}^{L-1}\sum_{m=0}^{M-1} \alpha_l \beta_m R_p(nT - iT + \theta_m - \tau_l) \\ &\quad + \widetilde{n}_0(nT), \end{aligned} \quad (6)$$

where $R_p(t) \triangleq \int_{-\infty}^{\infty} p(\tau)p(\tau + t)d\tau$ is the time auto-correlation of the pulse shape and $\widetilde{n}_0(t) = \sum_{m=0}^{M-1} \beta_m \cdot \int_{-\infty}^{\infty} n_0(\tau)n_0(-t + \tau - \theta_m)d\tau$ is filtered noise.

It is well known that the optimal combiner for the AWGN multi-path channel is MRC, where $M = L$ fingers, $\beta_m = \alpha_m$ and $\theta_m = \tau_m$. For UWB-based high rate, it is anticipated

that spreading codes will be short, and therefore MRC is suboptimal even when the noise is AWGN. This motivates a smarter choice of combining weights β_m and finger delays θ_m to combine the signal energy while compensating for the effects of ISI and narrowband interference.

D. Channel Estimation Model

Nowadays, the training sequence is popular in wireless communication, easily applied to other communication and low complexity for estimating channel response. Therefore, the least square (LS) and minimum mean square error estimators (MMSE) are used in our investigation.

The LS estimation method is used to estimate channel impulse response of the received signal. For this method, it does not require an expression for the PDF $p(r,h)$ in order to estimate the unknown parameter h or the channel impulse response (CIR) but requires the training sequence. The LS estimation for this investigation can be expressed as [13]

$$\hat{\mathbf{h}}_{LS} = (\mathbf{S}^T\mathbf{S})^{-1}\mathbf{S}^T\mathbf{y}, \tag{7}$$

where $\mathbf{S}$ is the known observation matrix containing the transmitted data, $(\ )^T$ and $(\ )^{-1}$ denote the transpose and inverse matrices, respectively, and $\mathbf{y}$ is the received signal.

For the special case of time variant channel with AWGN, the linear MMSE estimator of the CIR can be used. Therefore, the MMSE estimator is used [14]. The result is

$$\hat{\mathbf{h}}_{MMSE} = R_c\mathbf{S}^T(\mathbf{S}R_c\mathbf{S}^T + \sigma_n^2 I)^{-1}\mathbf{y}, \tag{8}$$

where R_c is covariance matrix of $R_c = E\{\mathbf{h}\mathbf{h}^H\}$ [15], $\mathbf{S}$ is matrix of data signals, σ_n^2 is the variance of noise and I is identity matrix.

A natural optimal criterion is minimization of the mean square error and can be expressed as

$$MSE(\hat{\mathbf{h}}_{LS,MMSE}) = E[(\hat{\mathbf{h}}_{LS,MMSE} - \mathbf{h})^2], \tag{9}$$

where $\hat{\mathbf{h}}_{LS,MMSE}$ is the LS or MMSE channel estimation result and $\mathbf{h}$ is channel impulse response.

III. Performance Results

In this investigation, the LS and MMSE estimators are used to estimate the channel impulse responses of the received signal, according to CM1-4 models and the combining of the channel impulse response between the S-V model and the human body shadowing. The mean square errors of the channel estimator versus the signal to noise ratio are shown in Fig. 2. From the results, the MSE decreases as the SNR increases. Therefore, the performance of MMSE estimator is higher than LS estimator. For the example, the mean square error at 10^{-1} of the MMSE and the LS estimator differ by about 5 dB of SNR.

The performances of the 3 different UWB Rake receivers namely, the Rake receiver with perfect channel estimation, MMSE and LS channel estimators,and the correlation receiver with perfect synchronization are evaluated. The CIR combination of 4 S-V channel models and the human body shadowing

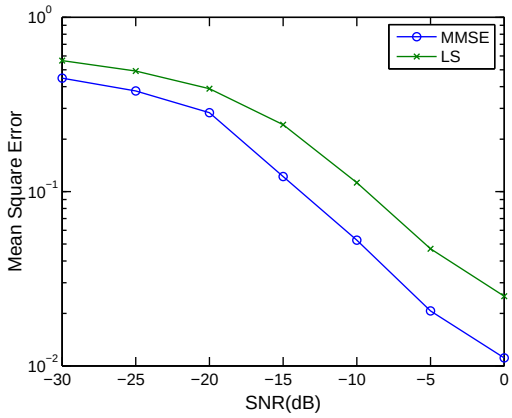

Fig. 2. Mean square errors versus SNR of the least square and minimum mean square error estimator.

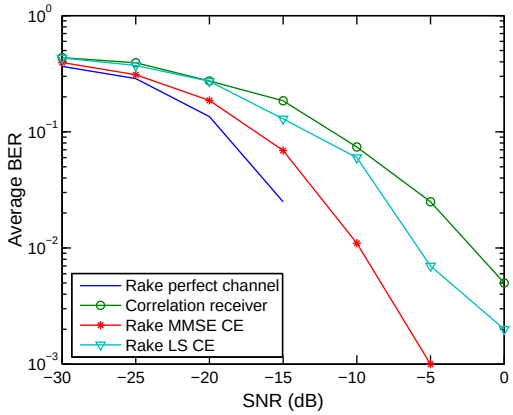

Fig. 3. Average BER performance of 4 UWB receivers in realistic indoor channel based on the combining of CM1 and human body shadowing effects.

are considered. Fig. 3- Fig. 6 show the performances of the UWB receivers for CM1-CM4 environments, respectively.

The performances of the UWB receivers based on the line-of-sight communication with the distance of 0-4 meters or the CM1 environment are shown in Fig. 3. It can be observed that the performance of Rake receiver with perfect channel estimator is best among overall and the correlation receiver with perfect synchronization is the worst for all receivers. Moreover, the performance of MMSE Rake receiver is better than LS Rake receiver by about 5 dB at BER of 10^{-2}.

Fig. 4-Fig. 6 show the performances of the UWB receivers for CM2-CM4 environments. As the results, the performances of the UWB receivers for all environments are similar with CM1 performance. Then, the performance of UWB Rake receiver with perfect channel estimator is best for all receivers, the receiver with MMSE channel estimator is better than LS channel estimator and correlation receiver, respectively. However, the UWB Rake receiver with the MMSE estimator can be used in the realistic indoor channel.

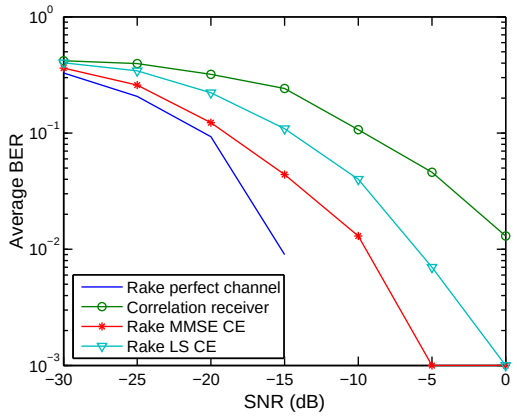

Fig. 4. Average BER performance of 4 UWB receivers in realistic indoor channel based on the combining of CM2 and human body shadowing effects.

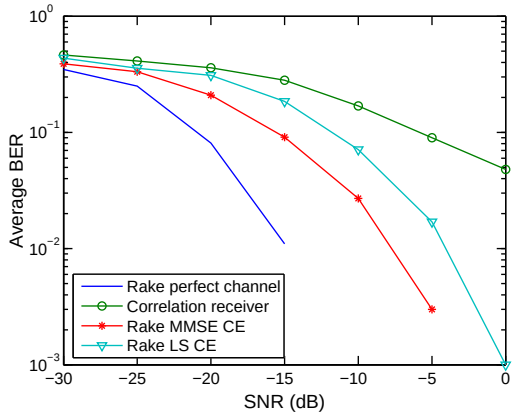

Fig. 5. Average BER performance of 4 UWB receivers in realistic indoor channel based on the combining of CM3 and human body shadowing effects.

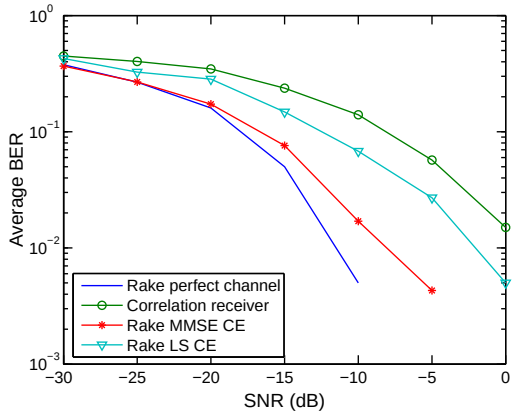

Fig. 6. Average BER performance of 4 UWB receivers in realistic indoor channel based on the combining of CM4 and human body shadowing effects.

IV. Conclusions

The performances of the UWB Rake receivers with LS and MMSE channel estimators in realistic environment are investigated. The performance of the Rake receiver with perfect channel estimation, LS and MMSE channel estimations and the correlation receiver with perfect synchronization are compared, based on the combining of the channel impulse response of the human body shadowing and the S-V channel model. As the simulation results, the mean square error (MSE) for all receivers decreases as SNR increases. The performances of the Rake receiver with perfect channel estimation are best for all receivers and environments. Moreover, the performances of the Rake receiver with MMSE channel estimator are better than with the LS channel estimator for all realistic indoor environments but it has much higher complexity than the LS estimator. Therefore, the MMSE channel estimator is one of the candidate for UWB Rake receiver in realistic indoor channel.

***Abstract*— Ultra wideband (UWB) is currently wide interesting technology of wireless communication technology in building and home entertainment so the line-of-sight (LOS) and non-line-of-sight (NLOS) environments have effect on attenuation and other. In this paper, the LOS/NLOS propagation channel for UWB radio communications are evaluated. A vector network analyzer (VNA) is used to measure the frequency transfer functions of the radio channels over the frequency ranged from 3.1 10.6 GHz. The biconical antennas are used as transmitter (Tx) and receiver (Rx) antennas. The measurement is performed in the corridor with LOS and NLOS (wall obstruction) environments along the distance from 1-7 m. The matched filter is used at the receiver to maximize signal-to-noise ratio (SNR) of the received signal. The results are discussed in the conclusion.**

Keywords: **UWB line-of-sight, non-line-of-sight, path loss**

I. INTRODUCTION

Ultra Wideband (UWB) technology, a revolutionary approach to radio communications, allows systems to operate across a range of frequency bands defined by FCC [1] with negligible interference to existing systems in that band. This is because UWB uses very low power spectral density (PSD), while maintaining a high data rate. The UWB techniques can also provide reliable location information, high resolution imaging and work efficiently in a cluttered environment. The UWB technology is an ideal candidate that can be utilized for commercial, short-range, low power and low cost indoor communication systems such as wireless personal area networks (WPANs) [2], [3]. Moreover, this channel model was mainly aimed for short range applications (i.e. $<$ 10 m).

Indoor environment is one of the operating environments defined in [4] based on the applications envisioned for IEEE 802.15.4a standard as identified in [5]. Several channel measurements based on the indoor environments have been reported in the literature [6]-[9], but most of these measurements were conducted on the IEEE 802.15.4a standard, which was conducted in a flat. Furthermore, these measurements were aimed to investigate propagation channel for long range applications. This implies that more channel measurements are required in order to gain more profound knowledge of the UWB channel behaviors in this environment.

This paper report an extensive UWB measurement campaigns conducted in the types of corridor. The aim of this paper is to present the measurement of line-of-sight (LOS) and non-line-of-sight (NLOS, wall obstruction) environments along the distance from 2 to 7 m. The UWB path loss is evaluated and shown. The path loss characteristics are discuses. The frequency transfer functions of the radio channels are measured by using a vector network analyzer (VNA) over the frequency ranged from 3.1 GHz $\sim$ 10.6 GHz. The biconical antennas are used as transmitter (Tx) and receiver (Rx) antennas. The measurement data in term of the distance and frequency dependency of transmission gain are analyzed. Based on this, more measurement results can be provided for the standardization activities in IEEE 802.15.3a channel modeling.

II. ULTRA WIDEBAND ANALYSIS

A. UWB transmission theory

The Friis' transmission formula [10] has been widely used to evaluate the link budget for the narrowband LOS channels.

The UWB transmission signal waveform, its distortion due to the channel, and the receiver. Friis' transmission formula is extended for calculating the UWB free space link budget. For free space model, channel transfer function $H_{\rm c}$ are expressed as

$$H_{\rm c,f}(f,d) = H_{\rm f}(f,d)\vec{H}_{\rm r}(f,\frac{\pi}{2},\pi)\cdot\vec{H}_{\rm t}(f,\frac{\pi}{2},0), \quad (1)$$

where $H_{\rm f}$ is the free space transfer function which is expressed as

$$H_{\rm f}(f,d) = \frac{c}{4\pi f d}e^{-j2\pi f d/c}. \quad (2)$$

The complex transfer function vector of the antenna $\vec{H}_a$ relative to the isotropic antenna towards the $(\theta,\ \varphi)$ direction

$$\vec{H}_a(f,\theta,\varphi) \quad = \quad \hat{\theta}H_{a\theta}(f,\theta,\varphi) + \hat{\varphi}H_{a\varphi}(f,\theta,\varphi), \quad (3)$$

where a = r *or* t, θ and φ are the azimuthal and polar angles of spherical coordinates. Unit vectors $\hat{\theta}$, $\hat{\varphi}$ express the polarization and are defined with respect to the local spherical coordinates of the antennas.

The receiver input voltage $v_{\rm r}(t)$ of free space model is given as

$$v_{\rm r}(t,d) = \int_{-\infty}^{\infty} H_{\rm c,f}(f,d)V_{\rm t}(f)e^{j2\pi f t}{\rm d}f, \quad (4)$$

where $V_{\mathrm{t}}(f)$ is the spectral density of the transmitted signal that is calculated by using Fourier transform of its time domain waveform as

$$V_{\mathrm{t}}(f) = \int_{-\infty}^{\infty} v_{\mathrm{t}}(t) e^{-j2\pi ft} \mathrm{d}t. \quad (5)$$

At the receiver, the matched filter $H_{\mathrm{MF}}(f)$ is using for improvement signal-to-nosie ratio (SNR) of the received signal waveform that can be written as below

$$H_{\mathrm{MF}}(f) = \frac{\sqrt{2f_{\mathrm{b}}} H^{*}_{\mathrm{Friis}}(f)}{\sqrt{\int_{-\infty}^{\infty} |H_{\mathrm{Friis}}(f)|^2 df}}, \quad (6)$$

which satisfies the following constant noise output power condition

$$\int_{-\infty}^{\infty} |H_{\mathrm{MF}}(f)|^2 df = 1. \quad (7)$$

In this case, the output waveform when $E_i = 1$, and the spectrum of the receiver output are $h_{\mathrm{e-Friis}}(t)$ and $H_{\mathrm{e-Friis}}(f)$, respectively. The waveform of the output from the match filter $v_{\mathrm{MF}}(t)$ and the spectrum of the output from the matched filter $V_{\mathrm{MF}}(f)$ are

$$\begin{aligned} v_{\mathrm{MF}}(t) &= h_{\mathrm{e-Friis}}(t) * h_{\mathrm{MF}}(t) \\ &= \frac{h_{\mathrm{e-Friis}}(t) * h_{\mathrm{MF}}(-t)}{\sqrt{\int_{-\infty}^{\infty} h^2_{\mathrm{e-Friis}}(t) dt}}, \end{aligned} \quad (8)$$

$$\begin{aligned} V_{\mathrm{MF}}(f) &= H_{\mathrm{e-Friis}}(f) H_{MF}(f) \\ &= \frac{|H_{\mathrm{e-Friis}}(f)|^2}{\sqrt{\int_{-\infty}^{\infty} |H_{\mathrm{e-Friis}}(f)|^2 df}}, \end{aligned} \quad (9)$$

take its maximum as

$$\max_t v_{\mathrm{MF_t}} = \frac{\int_{-\infty}^{\infty} V_{\mathrm{MF}}(f) df}{\sqrt{\int_{-\infty}^{\infty} |H_{\mathrm{e-Friis}}(f)|^2 df}}, \quad (10)$$

Eq.(10)is the UWB extension of Friis' transmission formula. It includes three elements, namely the frequency characteristics of free space propagation, and the spectrum of the transmit signal. It is clear from Eq.(10)that the transmission gain of the UWB cannot be defines as the product of gains of antenna and a free space channel as a Friis' formula[10]. Instead, the total transmission gain including the effect of the waveform can be obtained as Eq.(10).

B. Path loss

The path loss PL [11] can be defined as the ratio between the maximum amplitude of the transmitted signal waveforms and output waveform of the matched filter

$$PL(dB) = 20 \log \frac{max|v_{\mathrm{t}}(t)|}{max|v_{\mathrm{MF}}(t)|}. \quad (11)$$

TABLE I
PARAMETERS OF EXPERIMENT

Parameter	Value
Frequency range	3 GHz - 11 GHz
Number of frequency point	801
Dynamic power range	80
Tx antenna height	1.5 m
Rx antenna height	1.5 m
Distance between Tx and Rx	1-7 m
Distance increment step by	0.5m

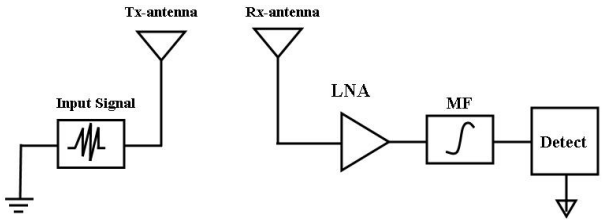

Fig. 1. Block diagram of System Analysis for UWB.

III. EXPERIMENTAL SYSTEM

A. Experiment setup

The UWB radio channel transfer function is measured. The measurement system consists of the VNA model HP-8510C, the S-parameter test set (HP-8514B), the frequency synthesized sweeper (HP-83620A), the biconial antenna pair and the personal computer. The VNA is operated in the response measurement mode, where PORT1 is the Tx port and PORT2 is the Rx port. The biconical antennas with the maximum diameter of 65.3 mm and the length of 37 mm are used as the Tx and Rx antennas. Table 1 lists the main parameters of the experiments.

The measurement is done on 12 floor Engineering Building at King Mongkut's Institute of Technology Ladkrabang (KMITL). Two models are considered for the LOS and NLOS environments, respectively. The first model for LOS environment and second model for NLOS environment are shown in Fig 2.

B. Transmitted signal waveform

The effect of the waveform distortion is more obvious when the bandwidth is wider. We considered the impulse radio signal with center frequency is at the center of lower band of preliminary UWB transmission mask for impact analysis of Japan. That is $f_{\mathrm{c}} = 4.1$ GHz. Three cases of the spectral bandwidths are considered. The bandwidths are set to be $B = 0.5$, 0.95 and 1.4 GHz, which are the minimum UWB bandwidth defined by FCC, middle and maximum UWB bandwidths of the lower band. The UWB transmitted signal in the simulation was the passband rectangular pulse. Figure 3 shows the transmitted pulse waveforms with 0.5, 0.95 and 1.4 GHz bandwidths. The expression of this pulse in time domain

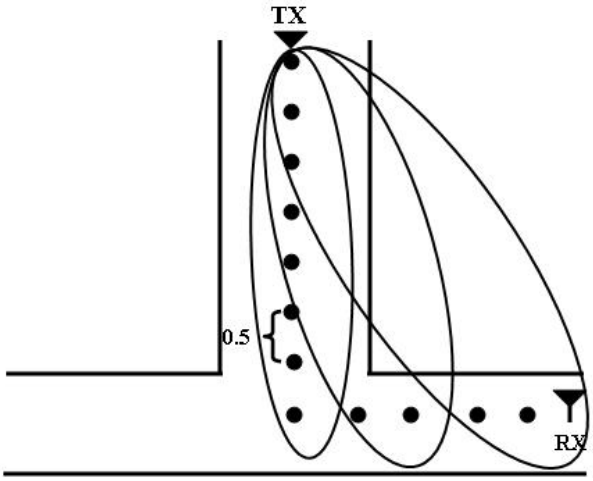

Fig. 2. The measurement model with corridor.

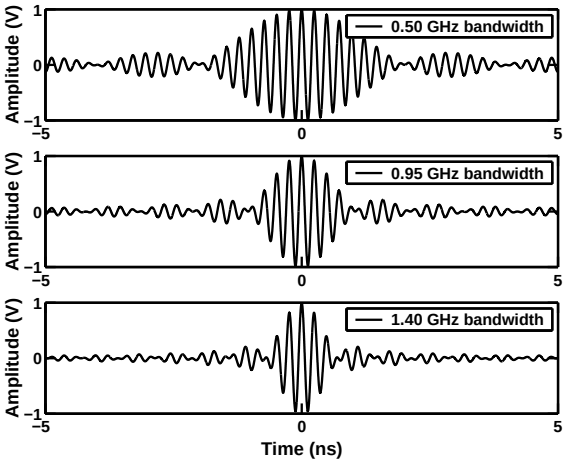

Fig. 3. UWB transmitted signal waveform.

$v_{\rm t}(t)$ and its spectral density function $V_{\rm t}(f)$ were

$$v_{\rm t}(t) = \frac{\sqrt{2}}{\sqrt{B}}\left[\ f_{\rm H}{\rm sinc}(2f_{\rm H}t) - f_{\rm L}{\rm sinc}(2f_{\rm L}t)\ \right], \quad (12)$$

$$V_t(f) = \begin{cases} \frac{1}{\sqrt{2B}} & ||f| - f_c| \le \frac{B}{2} \\ 0 & ||f| - f_c| > \frac{B}{2} \end{cases}, \quad (13)$$

where ${\rm sinc}(x) = \sin(\pi x)/(\pi x)$, $f_{\rm L} = f_{\rm c} - B/2$ and $f_{\rm H} = f_{\rm c} + B/2$ are the lower and upper frequencies.

IV. Results and Discussion

The transmission losses of UWB signals with optimum and isotropic matched filters in corridor LOS and NLOS environments are evaluated. The three cases of signal bandwidths, that are 0.50, 0.95 and 1.40 GHz, are considered. Fig. 4 shows the transmission losses of 0.50 GHz signal bandwidth with optimum and isotropic matched filters in corridor LOS and NLOS environments along the distance from 2 to 7 m. The transmission loss of optimum matched filter is less than that of isotropic matched filter about 1.8 and 6.79 dB for the LOS and NLOS, respectively. The obstruction loss is about 12.47 dB.

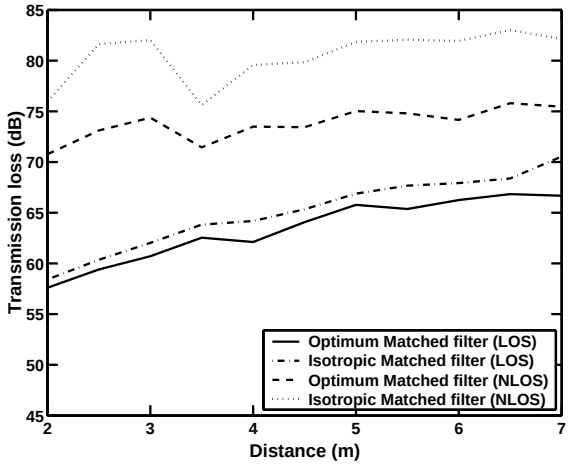

Fig. 4. Transmission losses of 0.5 GHz bandwidth along the distance from 2 to 7 m.

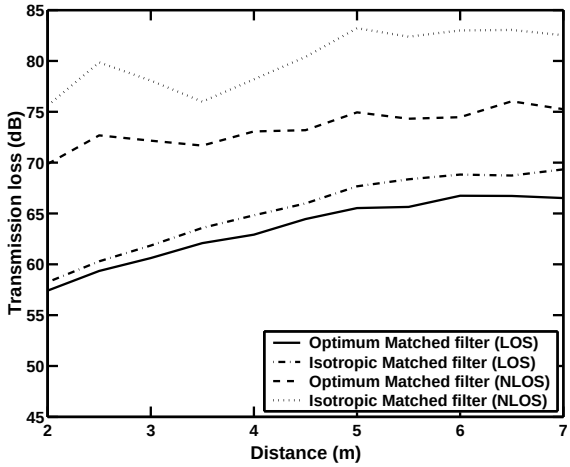

Fig. 5. Transmission losses of 0.95 GHz bandwidth along the distance from 2 to 7 m.

The transmission losses of 0.95 GHz signal bandwidth with optimum and isotropic matched filters in corridor LOS and NLOS environments along the distance from 2 to 7 m are shown in Fig. 5. The transmission loss of optimum matched filter is less than that of isotropic matched filter about 1.65 and 6.70 dB for the LOS and NLOS, respectively. The obstruction loss is about 12.94 dB.

Fig. 6 shows the transmission losses of 1.40 GHz signal bandwidth with optimum and isotropic matched filters in corridor LOS and NLOS environments along the distance from 2 to 7 m. The transmission loss of optimum matched filter is less than that of isotropic matched filter about 1.71 and 6.70 dB for the LOS and NLOS, respectively. The obstruction loss is about 12.42 dB.

V. Conclusion

In this paper, UWB radio propagation channel with corridor for short range wireless systems. From the results, the

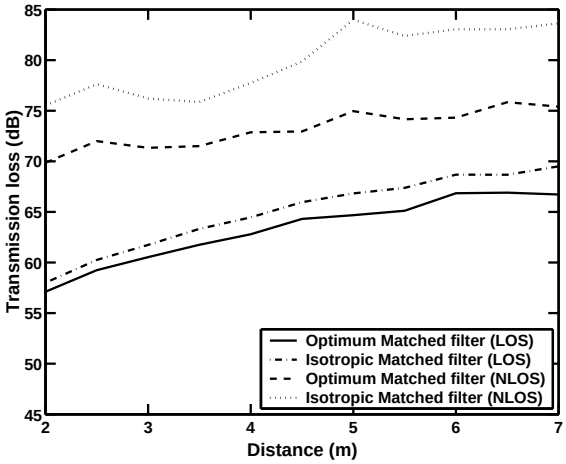

Fig. 6. Transmission losses of 1.4 GHz bandwidth along the distance from 2 to 7 m.

transmission loss of the optimum matched filter is better than that of the isotropic matched filter for all cases of the signal bandwidths. The obstruction loss of each signal bandwidth is almost the same. Based on this, the measurement results can be used for the standardization activities in IEEE 802.15.3a channel modeling.

***Abstract*- This paper presents a modified decision feedback adaptive equalizer for turbo coded direct-sequence code division multiple access (DS-CDMA) system using soft output viterbi algorithm (SOVA) decoding. The modified decision feedback equalizer (MDFE) structure is based on the decision feedback equalizer (DFE) structure. And the adaptation process of the equalizers is using the most commonly least mean square (LMS) adaptive algorithm. The simulation results are shown that the bit error rate (BER) performance of the MDFE with the SOVA decoding outperforms other equalizers structure such as the finite impulse response (FIR) equalizer and the conventional decision feedback equalizer (DFE).**

I. INTRODUCTION

Direct sequence code division multiple access (DS-CDMA) is a candidate access technique for a third generation mobile system [1]. In DS-CDMA systems, signal transmission over time-varying multipath mobile radio channel produces intersymbol interference (ISI), multiple access interference (MAI), and other time-varying effect from the channel. In this case, a DS-CDMA receiver with channel equalization is generally required to mitigate the effect of ISI and MAI signals. There are many kinds of the equalizers structure such as the finite impulse response (FIR) equalizer, the conventional decision feedback equalizer (DFE) [2,11] and the modified decision feedback equalizer (MDFE) [3]. The last one equalizer structure that was proposed by author can improve the performance of the system, which is considered in this paper.

Turbo coding [4] has been adopted as a channel coding scheme for several third generation mobile system in particular third generation partnership project (3GPP) for high data rates. It provides significant improvements in the quality of data transmission over a noisy channel. Iterative log-maximum a posteriori algorithm (Log-MAP) and soft output viterbi algorithm (SOVA) decoding are an important kind of turbo decoding algorithms [5-7]. However, SOVA is less complex [7]: the algorithm shares some operations [8]. Therefore, SOVA solutions have to be considered in this paper.

In this paper presents a modified decision feedback adaptive equalizer for turbo coded direct-sequence code division multiple access (DS-CDMA) system using soft output viterbi algorithm (SOVA) decoding.

The paper is organized as follows. Section II, the system model for the DS-CDMA system is presented. In section III presents the turbo codes system herein including turbo encoder and the prime candidates SOVA decoding turbo codes. Section IV, the conventional decision feedback equalizer and the modified decision feedback equalizer are presented. In section V presents the least mean square adaptive algorithm for update the coefficient of the equalizers. Computer simulations for several situations to demonstrate the performance of the system and conclusions are given in section VI and VII, respectively.

II. SYSTEM MODEL

We consider the real signal model of an Additive White Gaussian Noise (AWGN) *K*-user synchronous DS-CDMA channel that the baseband received signal [3] is defined as:

$$r(n) = \sum_{i=0}^{\infty} \sum_{k=0}^{K-1} d_i^k c_k (n - i\tau) * h_k(n) + n(n) \qquad (1)$$

where modulation scheme is linear. d_i^k is the *k*th symbol of duration T_s, transmitted by user *i*. and T_c is the chip duration ($T_c = T_s / L_c$) and $c_k \in \{-1,1\}$.

The minimum value of τ is: $\tau = T_s + (W\text{-}1)\ T_c$.. $n(n)$ is a complex additive white gaussian noise with zeros mean and a variance of σ^2.

The spread signal is transmitted over the frequency and time selective channels, where $h_k(n)$ is given as follows [2]:

$$h_k(n) = \sum_{i=0}^{W-1} a_i^k \delta(n - iT_c) \qquad (2)$$

whose impulse response is given by:

$$a(n) = \left\{ \begin{array}{ll} 0.5\left\{1 + \cos(\frac{2\pi}{A}(n-2))\right\}, & n = 1,2,3 \\ 0 & ,otherwise \end{array} \right\} \qquad (3)$$

where the factor *A* is introduced to allow scaling to customize the simulated ISI.

III. TURBO CODES [9]

Parallel concatenation of at least two component codes with interleaver in between them forms a parallel-concatenated interleaved code, also known as a turbo code. A turbo code encoder with two component codes is shown in the Figure 1. Special types of convolutional codes, called recursive systematic convolutional codes (RSC), are used as the building blocks of a turbo code encoder.

The encoder ENC_1 and ENC_2 of the two component RSCs encode the same input information bits $x(n)$ but in a different order, because of the interleaver before the ENC_2. Appropriate puncturing of parity bits ($d2_n, d3_n$) from two encoders can produce a turbo code of desired rate ($d2,3_n$). In this study, two memory-2 recursive systematic convolutional codes (generate matrix 7_8, 5_8) are used as component codes and the puncturing matrix is used to get overall turbo code of rate ½ following the design in [6]. A fixed pseudorandom interleaver is used. It has been selected among randomly generated interleavers based in frequency of low-weight output codeword for weight-2 input sequences following methodology in [10].

The Figure 2 shows the structure of a turbo decoder. The two decoders (log-maximum a posteriori algorithm (Log-MAP) or soft output viterbi algorithm (SOVA) decoding) Decoder 1 (DEC_1) and Decoder 2 (DEC_2), corresponding to the constituent encoders ENC_1 and ENC_2, are serially connected through the same interleaver that is used in the encoder.

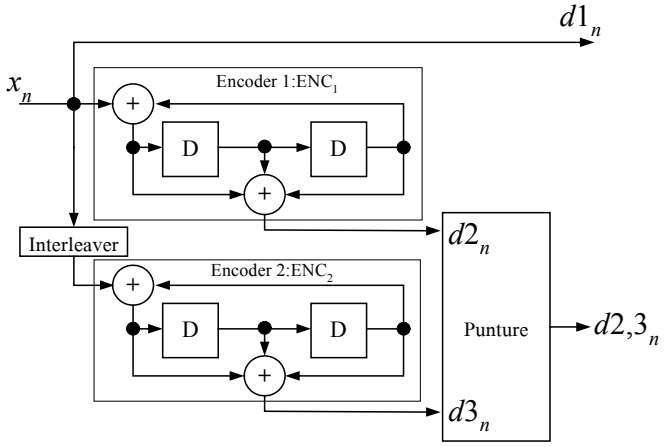

Figure 1. Turbo Encoder

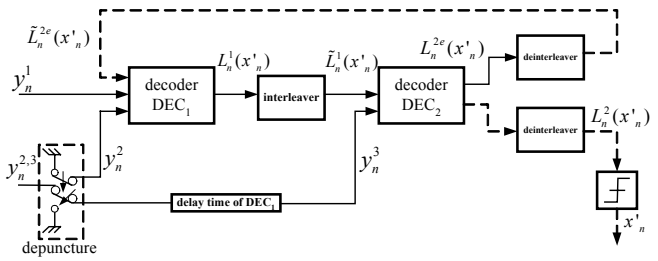

Figure 2. Turbo Decoder

The iterative turbo decoding is implemented using SOVA and Log–MAP algorithms in the soft input soft output (SISO) decoders described in [9,10]. Appropriate soft output $y_n^1, y_n^{2,3}$ from the depuncture y_n^2, y_n^3 are used as inputs of both the decoders. The values of a priori probability distribution for information bits $\tilde{L}_n^{2e}(x'_n), \tilde{L}_n^1(x'_n)$ are initialized for the first iteration by assuming information bits to be equally probable. However, after the first decoding step $\tilde{L}_n^{2e}(x'_n)$ will be available from the soft outputs of information bits $L_n^1(x'_n), L_n^{2e}(x'_n)$ computed in the previous decoding stage. The SISO decoder of [10] can be used to compute extrinsic information corresponding to both information bits $L_n^1(x'_n), L_n^{2e}(x'_n)$ and coded bits $L_n^2(x'_n)$ in general. However, for iterative decoding of a turbo code only $L_n^{2e}(x'_n)$ are required, and it is passed to next decoder after each decoding step to improve the correction capacity of decoding. Detection is made after the final iteration by adding the a posteriori probability values of the information bits $L_n^2(x'_n)$ from the output of the last decoding stage to the values of a priori distributions $\tilde{L}_n^1(x'_n)$.

In this paper SOVA solutions have to be considered. We will briefly describe the attractive SOVA decoding turbo codes in next section.

The Viterbi Algorithm (VA) [12] was originally proposed for decoding of convolution codes. Here we will present SOVA algorithm which development by VA. The SOVA estimates the soft output information for each transmitted binary symbol in the log-likelihood function $L(x'_n)_{SOVA}$, as follows:

$$L(x'_n)_{SOVA} = \log\frac{P_r(s_n = 1 \mid y_1^\tau)}{P_r(s_n = 0 \mid y_1^\tau)} \approx \log\frac{e^{-\mu_{\tau,\min}}}{e^{-\mu_{t,s}}} \approx \mu_{t,s} - \mu_{\tau,\min} \quad (4)$$

where P_r is a *posteriori* probability , s_n is the spread signal of the transmitted symbol, $\mu_{\tau,\min}$ is the minimum path metric as the maximum likelihood (ML) , $\mu_{n,s}$ is the minimum path metric of the paths with complementary symbol to the ML symbol at time *n*. If the ML symbol at time *n* is 1, then its complementary symbol is 0. Therefore, we can write [5]:

$$P_r(s_n = 1 \mid y_1^\tau) \approx e^{-\mu_{\tau,\min}} \quad (5)$$

$$P_r(s_n = 0 \mid y_1^\tau) \approx e^{-\mu_{n,s}} \quad (6)$$

IV. THE EQUALIZER STRUCTURES

A. Decision feedback equalizer (DFE) structure

The DFE, first introduced by Austin[11], shows significant performance gain by adding decision feedback filter to linear equalizer (LE). It consists of feed-forward filter and decision feedback filter. The DFE that has feed-forward filter of *M*-1 taps and feedback filter of *N*-1 taps. We assume that the input

vector, R_n^k, and filter coefficient vector, $W_{w,v}$ with time index n is given by:

$$R_n^k = [r^k(n) r^k(n-1) \ldots r^k(n-(M-1)) \; y_{H1}^k(n-1) \ldots y_{H1}^k(n-(N-1))]^T \quad (7)$$

$$W_{w,v} = [w_0 \; w_1 \ldots w_{M-1} \quad v_1 \ldots v_{N-1}]^T \quad (8)$$

where $r^k(n)$ is the input signal and $y_{H1}^k(n)$ is the decision value of the equalizer output.

Then, the output before decision of the DFE can be expressed as:

$$y_{d1}^k(n) = \sum_{i=0}^{M-1} w_i r^k(n-i) + \sum_{i=0}^{N-1} v_i y_{H1}^k(n-(i+1)) \quad (9)$$

$$= W_{w,v}^H R_n^k \quad (10)$$

where H stand for Hermitian transpose, $y_{d1}^k(n)$ is the output before decision of the DFE can be expressed as:

$$y_{d1}^k(n) = y_{ff1}^k(n) + y_{fb1}^k(n) \quad (11)$$

The error between the desired signal $d^k(n)$ and the filter output $y_{ff1}^k(n)$ is defined as:

$$e_{ff1}(n), e_{fb1}(n) = d^k(n) - y_{ff1}^k(n) \quad (12)$$

B. The modified DFE equalizer (MDFE) Structure [3]

This section, the modified decision feedback equalizer (MDFE) structure is presented. The equalized output signal of the MDFE adaptive equalizer is the sum of the outputs of the feed-forward part and feedback part of the equalizer. Decisions made on the equalized signal are only feedback to a feedback part of the equalizer. By this structure, it is suitable for turbo code decoding of the DS-CDMA systems. Therefore, the output $y_{ff2}^k(n)$ of the feed-forward part is given by:

$$y_{ff2}^k(n) = \sum_{i=0}^{M-1} w_i r^k(n-i) \quad (13)$$

The output $y_{fb2}^k(n)$ of the feedback part is given by:

$$y_{fb2}^k(n) = \sum_{i=1}^{N-1} v_i y_{df2}^k(n-(i+1)) \quad (14)$$

where $y_{df2}^k(n)$ is the decision output of $y_{ff2}^k(n)$ can be expressed as:

$$y_{df2}^k(n) = sign\left[y_{ff2}^k(n) \right] \quad (15)$$

Then, the output $y_o^k(n)$ of the MDFE can be expressed as:

$$y_o^k(n) = y_{ff2}^k(n) + y_{fb2}^k(n) \quad (16)$$

The error between the desired signal $d^k(n)$ and the filter output $y_{ff2}^k(n)$ of MDFE is given as:

$$e_{ff2}(n), e_{fb2}(n) = d^k(n) - y_{ff2}^k(n) \quad (17)$$

V. The Adaptive Algorithm for The Equalizers

The general problem is to estimate the desired discrete time signal $d^k(n)$ using past values $d^k(n\text{-}1)$, $d^k(n\text{-}2)$, …, and samples from a reference signal $\{r^k(n)\}$, from Eq.(8), the weights of feedback part of the equalizer using the least mean square (LMS) algorithm [2] are updated according to:

$$w(n+1) = w(n) + \mu_{ff} e_{ff}(n) r^k(n) \quad (18)$$

where μ_{ff} is a fixed step-size parameter of feed-forward filter part.

The weights of feedback filter part are updated as:

$$v(n+1) = v(n) + \mu_{fb} e_{fb}(n) y_{df}^k(n) \quad (19)$$

where μ_{fb} is a fixed step-size parameter of feedback filter part.

VI. Numerical Results

The BER performance of the modified decision feedback equalizer (MDFE) structure with SOVA decoding for turbo code DS-CDMA system receiver is presented in this section. The simulation results are obtained from the communication system over both ISI and MAI channels. The main system parameters are defined as follows: length of transmission information 15 kbits (15 x 1024), support 4 users, filter length of feed-forward part M = 11, feedback part N = 10, power of each user = 8 dB, and with 10 independents computer runs.

For turbo code parameters are defined as follows : channel code rate R = 1/2, and the number of iteration for turbo decoder = 1, code generator metric:

$$G = \left[1, \quad \frac{1 + D^2}{1 + D + D^2} \right] \tag{20}$$

with constraint length = 3.

Figure 3 shows the convergence processes of feed-forward and feedback part with adaptive algorithm for the equalizers with the Eb/No = 15 dB. Figure 4 shows the average BER performance of the perfect power control versus Eb/No for various values of the MDFE with SOVA decoding receiver. From this figure, it is seen that the MDFE provides a lowest BER performance for every Eb/No values.

Finally, Figure 5 shows the BER performance of the equalizer as a function of the number of decoder iterations. From Figure 5, it is evident that the BER performance of the equalizer is directly proportional to the number of decoder iterations.

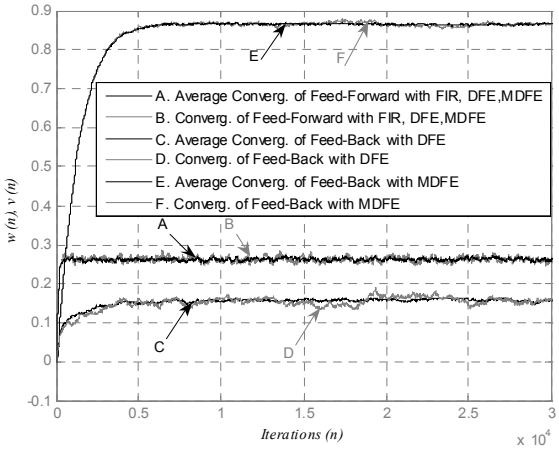

Figure 3. The convergence processes of feed-forward coefficients and feedback coefficients of the equalizers with Eb/No = 15 dB.

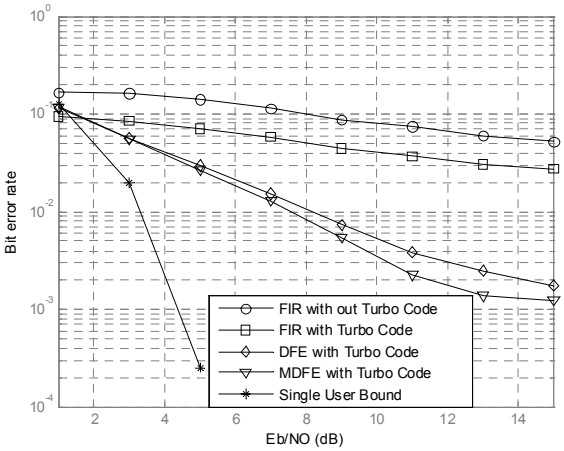

Figure 4. The BER performance of the equalizers using SOVA decoding.

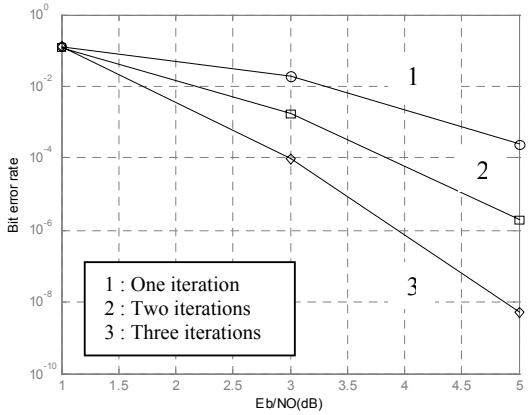

Figure 5. The BER performance of Single User Bound (SUB) as a function of Eb/No and multiple iterations.

VII. CONCLUSION

In this paper presents a powerful adaptive equalizer that using the LMS algorithm to control the adaptation process of the modified decision feedback equalizer (MDFE) and followed by the attractive SOVA algorithm for the turbo decoding process of the communication system. Our simulation results shown that the BER performances of the MDFE for the DS-CDMA communication systems are greatly outperformed then other equalizers. Finally, the performance of the equalizer is achieved as a function of the number of decoder iterations.

***Abstract*–This paper describes a channel estimation method for space–time block code multi–carrier code division multiple access (STBC MC–CDMA) system as operating on multi-path fading channel with minimum mean square error (MMSE) detection scheme. In the proposed method, the design of orthogonal preamble symbols in time domain for separate impulse response of each channel is presented and threshold method in which an optimal threshold value can be selected to eliminate the noise signal in channel estimation. The simulation results are shown that the proposed technique can improve the performance of the system.**

I. INTRODUCTION

MC-CDMA system is expected that it has received a great deal for future fourth-generation wireless systems (4G) [1]. MC-CDMA inherits from orthogonal frequency division multiplexing (OFDM) characteristics such as high spectral efficiency and robustness against multi-part propagation, while from CDMA the benefit of a multiple access flexibility. In the past, a diversity technique as transmitter [2], [3] combined with STBC MC-CDMA [4] have been reported. It is a multi-input single-output (MISO) and a multi-input multi-output (MIMO) communication. Therefore, the effect of fading channel can be reduced. However, good performance of multiple antennas STBC MC-CDMA also depends on an accuracy of channel estimation of receiver part.

In this paper, a channel estimation technique for STBC MC-CDMA system is presented. The proposed technique based on least square (LS) channel estimation which can separate the channel impulse response of each transmit antenna by designing the preamble symbol with orthogonal in time domain and combined with threshold method. This proposed technique can reduce noise in the channel estimation.

II. MODEL OF SYSTEM

A. Transmitter and Receiver

Fig. 1(a) shows the block diagram of downlink STBC MIMO MC-CDMA system. The system uses N_C sub-carriers, N_t=2 be the number of transmit antennas and N_r=2 be the number of receive antennas. As Fig. 1(a), a stream of modulated signal of the u-th users is serial-to-parallel converted, where every V symbols are grouped into a vector. Each group vector is spread by the same Hadamart's sequence. After spreading, the spread vector of the v-th subdata, when v=1,2,…,V, are summed with symbol of other user. After that, a data with serial stream is converted to a parallel stream. A STBC will be applied to the MC-CDMA using Alamoutti's sequence [3]. To convert the frequency domain into the time domain, inverse fast Fourier transform (IFFT) is used. The outputs of IFFT are enters a parallel to serial converter and transmit to the receiver over the wireless channel.

At receiver, alternative transmit process will be used to detect the original data. In this paper, MMSE [3] single user detect scheme is investigated.

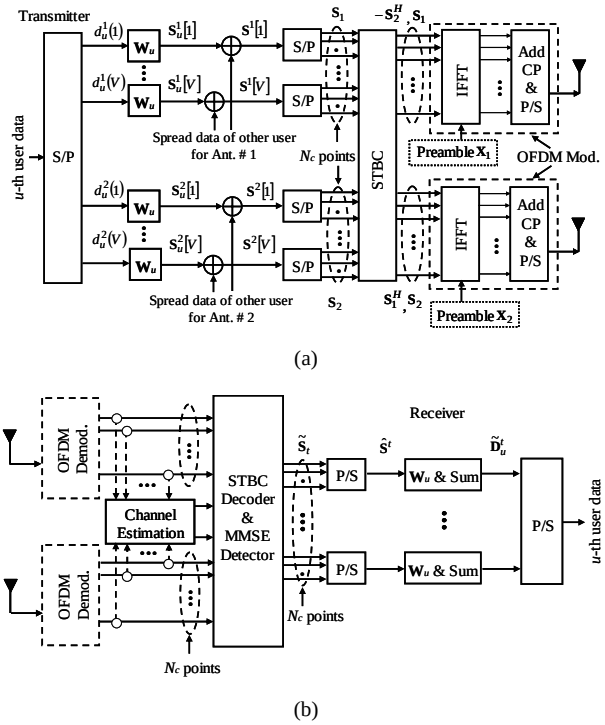

Fig. 1. Block diagram of MIMO MC-CDMA: (a) transmitter model, (b) receiver model.

B. Preamble Symbol Design and Channel Estimation

As the transmitter, a preamble for the 2 antennas is considered in this investigation. The preamble symbol is designed to be orthogonal in the time domain. It uses for separating the result of channel impulse response. The preamble for 2 transmit antennas can be formulated in the frequency domain by [2]

$$X_t(k) = X_1(k)e^{-j2\pi(t-1)N_t N_g k/N_c} \quad (1)$$

where $x_1(k)$ is the preamble symbol of the first transmit antenna as k-th subcarrier and N_g is the sample number of guard time interval. By using IFFT criterion, (1) can be expressed in the time domain by

$$x_t(n) = x_1\{(n-(t-1)N_t N_g)\}_{N_c} \quad (2)$$

when n=0,1,…,N_C-1. In (2), the preamble symbol of the t-th transmit antennas is the preamble symbol of the first transmit antenna with delay by (t-1)$N_t N_g$. Note that each multipath fading path of t-th transmit antennas to r-th receiver antennas are uncorelate and assumed that the two period of symbols are constant. After transmitted, the preamble symbol of each frame from each transmit antenna through the multipath fading channel. The received signal can be expressed by

$$x_r(n) = \sum_{t=1}^{N_t} x_t(n) \otimes h_{tr}(n) + n_r(n) \quad (3)$$

Assume the every receive antennas are received the signal at the same time. By using FFT criterion, it can be written as

$$X_r(k) = \sum_{t=1}^{N_t} X_t(k) H_{tr}(k) + N_r(k) \quad (4)$$

when $H_{tr}(k)$ is the channel frequency response as k-th subcarrier of t-th transmit antenna to r-th receive antenna. $N_r(k)=FFT\{n_r(n)\}$ is noise signal. The sum of channel frequency response from every transmit antennas can be approximated by Least square algorithm, as

$$\hat{H}_r(k) = X_r(k)/X_t(k) \quad (5)$$

To simplify for separating the channel impulse response of each transmit antenna, (5) is converted into the time domain, expressed as

$$\hat{h}_r(n) = \sum_{t=1}^{N_t} h_{tr}(n-(t-1)N_t N_g) + \tilde{n}_r(n) \quad (6)$$

If the time period of result from the channel impulse response is less than the guard time interval, the signal from t-th transmit antenna have channel impulse response to the r-th receive antenna. The receiver can be made orthogonal in time domain, as follows

$$\hat{h}_{tr}(n) = \hat{h}_r(n+(t-1)N_t N_g) \quad (7)$$

In the case of the results from channel impulse response decreased as exponential formula, the receive power signal is a few in the time domain. Accordingly, it can be neglected some of the sample of impulse response these low power signals, because these sample are sum between signal and the strong noise power. Whereas the low E_b/N_o can be achieved by using threshold level, which is relate E_b/N_o at receiver as shown in (8). The channel impulse response from each transmit antenna in (7) measured the level of signal by selecting only the channel impulse response sample have more power than or equal to the level of threshold, expressed as

$$Threshold = \beta \times Eb/No \quad (8)$$

$$\tilde{h}_{tr}(n) = \begin{cases} \hat{h}_{tr}(n), & if \left|\hat{h}_{tr}(n)\right|^2 \geq Threshold \\ 0, & Other \end{cases} \quad (9)$$

Eq. (9) will be converted to channel frequency response with FFT formula. This process is used for MMSE detection as follow [3].

III. Simulation Results

To evaluate the system performance, computer simulations to verify the performance of the MIMO MC-CDMA system of Fig. 1 were conducted following an extended specification of an IEEE 802.11a as listed in Table. The indoor propagation channel model in [5] is used for this simulation.

TABLE
Simulation Condition.

System parameters	Configuration
Occupied bandwidth	20MHz
FFT size (N_c)	64
Guard Interval (T_g)	0.8μs
Total symbol duration ($T_s=T_{FFT}+T_g$)	4μs
Subcarrier spacing ($1/T_{FFT}$)	312.5kHz
Length of Spreading code (M)	32
Modulation	QPSK
Center frequency (f_c)	5GHz
Transmission Rate	32Mbit/s
Multi-path channel Model	
Delay profile	Exponential
Number of paths	4
RMS Delay spread	50ns
Maximum Doppler frequency	33.4Hz

Fig. 2 shows the optimal threshold values depend on E_b/N_o of the system. The threshold level to give minimum MSE (β=0.003) of all E_b/N_o values (8dB, 12dB, and 16dB). Fig. 3 shows the comparison between MSE and Eb/N_o of system. The comparative of channel estimation with β=0.003 and conventional method, from the results the proposed channel estimation to increase the better performance. If E_b/N_o are large the performance of two method, it will be same. Accordingly, in case of the E_b/N_o will be increased, some of channel impulse response sample has low power will be cancelled and effect to the performance of the system. Fig. 4 shows the BER performance of channel estimation in 1 user. By the proposed method gives better performance than conventional method. As BER=10^{-4}, the use power of proposed method more than the perfect channel

estimation of SISO MC-CDMA, MISO MC-CDMA and MIMO MC-CDMA are 0.8dB, 1.3dB and 1.9dB, respectively. Fig. 5 shows the performance of three systems alternate with number of user. The results compared between the proposed channel estimation and perfect channel estimation shown the E_b/N_o=16dB.

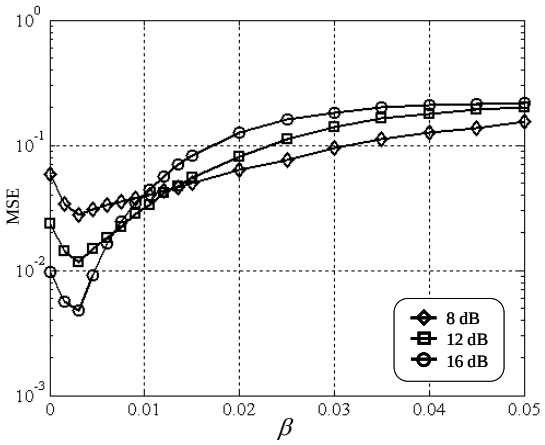

Fig. 2. The best of β level with Eb/No=8, 12 and 16 dB.

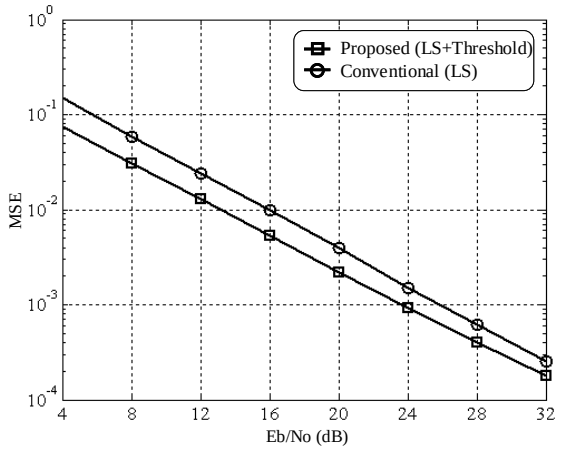

Fig. 3. Comparison of MSE between proposed channel estimation and conventional channel estimation.

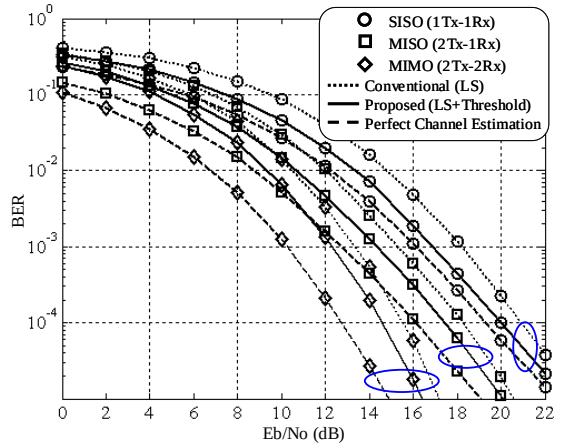

Fig. 4. Channel estimation performance for different systems in case of 1 user.

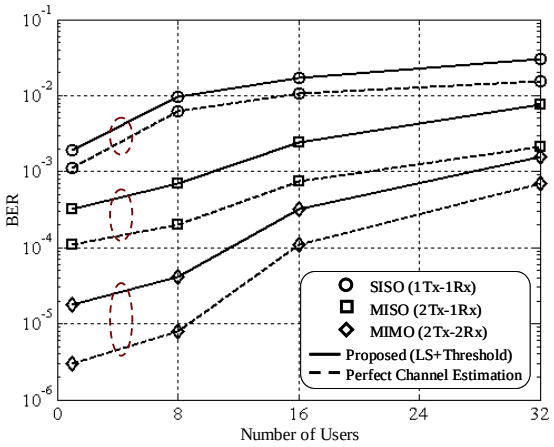

Fig. 5. Comparison of BER between number of users for SISO MC-CDMA, MISO-CDMA, and MIMO-CDMA systems.

IV. Conclusions

In this paper, we introduced a STBC MC-CDMA multipath fading channel estimation employing MMSE detector. The proposed method designs the preamble symbol with orthogonal in the time domain to simple for separate the channel impulse response of each transmit antenna and using the threshold technique to cannel noise in the channel estimation. The simulation results can be demonstrated that the proposed technique provides good performance.

***Abstract*- An Extend bi-directional arbitrated equalizer (E-BAD) algorithm is presented whose performance is improved from the conventional bi-directional arbitrated equalizer (BAD) algorithm while complexity is linear in the channel length. Modified method uses the benefit of low correlation errors among forward, reverse and extend soft-decision feedback equalizer (SD-DFE). The low correlation errors among three equalizers gain the whole algorithm performance to outperform to the conventional BAD.**

I. INTRODUCTION

The nonlinear classical decision feedback equalizer (DFE) technique is introduced by M.Austin [1] whose complexity and performance lie between that of linear equalization and equalization based on maximum likelihood (ML) or maximum *a posteriori* (MAP). The better performance of ML and MAP techniques has high complexity whose grow as A^L where A is the alphabet size and L is the channel length. Meanwhile, the error propagation is the big deal of DFE even with the perfect decision feedback. Many works proposed the way to mitigate error propagation by using dual decision feedback whose threshold is set for difference feedback. Threshold technique, however, may not be the best error propagation mitigating strategy. In fact, nonlinear equalizer (DFE) may outperform a linear equalizer by several decibels [2]. Recently work, a new bi-directional arbitrated equalizer (BAD) was proposed [3] and shown that the performance is better than classical DFE.

The BAD algorithm work by running the parallel forward and reverse equalizer DFE separately. The low correlations among errors over the entire block data in forward and reverse equalizers are adopted. The best match received data is decided. Each equalizer is separately designed for forward and reverse channel and the channel is assumed to be known to the receiver.

This work is supported by the National Electronics and Computer Technology Center (NECTEC) Thailand under the QT5001 project.

The BAD use the benefits of low correlation error between forward and reverse equalizer. In this paper, the extend equalizer is added in the BAD algorithm to gain the low correlation error by adding the third soft-decision feedback equalizer. We propose an E-BAD that the performance outperforms to the conventional BAD by adding soft-decision feedback equalizer.

The rest of this paper is organized as follows. In Section II, we start with the definition and the operation of the BAD algorithm. We then proceed with a detail for explanation in the modify of BAD algorithm. In Section III, we give the simulation result then the E-BAD result is compared with that of several other equalization methods.

II. THE PREVIOUS STRUCTURE AND THE PROPOSED STRUCTURE

A. BAD algorithm

The BAD [3] uses bi-directional DFE equalizer to recover channel inputs in forward and reverse direction as depicted in Fig. 1. Define the input sequence of uncoded as binary phase shift keyed (BPSK) data as a , $a_k \in \{\pm 1\}, k = 0,..., N-1$ over the channel impulse response $h_k, k = -L2,..., L1$. The receive data sequence $r_k, k = 0,..., N-1$ can be expressed as

$$r_k = \sum_{i=-L_2}^{L_1} a_{k-i} h_k + w_k \qquad (1)$$

where w_k is an Additive White Gaussian Noise (AWGN) with variance σ^2 . The channel h_k and noise variance σ^2 are assumed known to the receiver. The channel is assumed to be time-invariant for the duration of the packet data sequence.

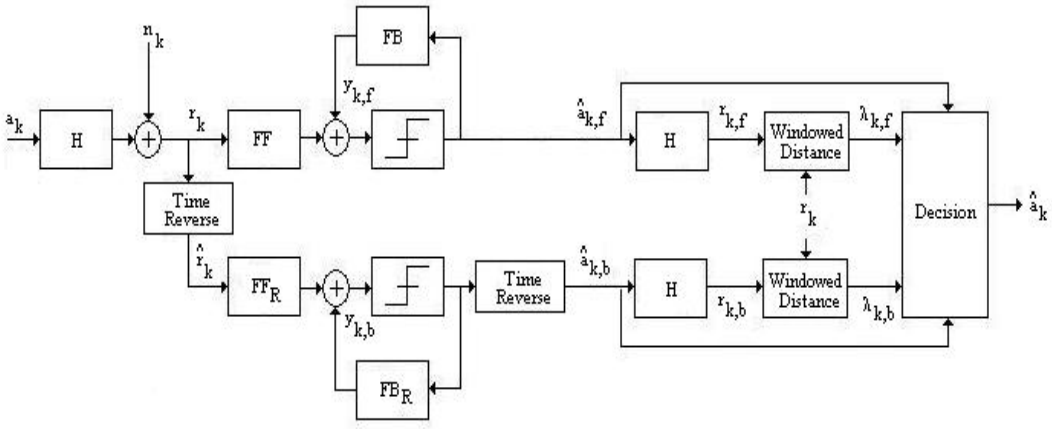

Fig. 1 Schematic of Bi-directional Arbitrated Decision Feedback Equalizer

The BAD equalizer consists of two DFE instructors which are separately designed for forward and reverse direction. The time-reversal operator for a length of N sequence of r_k can be expressed as

$$\hat{r}_k = r_{N-k} + 1, \qquad k = 0,\ldots,N-1 \qquad (2)$$

The upper DFE consists two filters: a feedforward filter tap coefficient $F = \{f_k\}, \{k = 0,..,M_f\}$ of length $M_f + 1$, and a causal feedback filter $B = \{b_k\}, \{k = 0,..,M_b\}$ of length M_b.

The equalizer tap coefficients are computed by using Recursive Least-Squares (RLS) algorithm. Hence, the equalized signal can be described as

$$y_{k,f} = \sum_{j=0}^{Mf} f_i r_{k-i} + \sum_{i=1}^{Mb} b_i \hat{a}_{k-i,f} \qquad (3)$$

At time k, $\hat{a}_{k,f}$ is made by slicing $y_{k,f}$ of both DFE directions which are separately designed by regarding to asymmetric channel. The lengths M_f and M_b depend largely on the channel are minimum, mixed, or maximum phase and on the length L_1 and L_2 [4].

Consider the ISI cancellation, the upper DFE is designed for normal channel and the lower DFE is independently designed for the time-reversal channel h_k. We can say that the precursor ISI is canceled by the upper DFE. While the lower DFE cancels the postcursor ISI.

The BAD algorithm has three stages: (1) bi-directional processing with forward and reverse DFEs, (2) data reconstruction and error calculation, and (3) data symbol arbitration. The output of two DFE are $\hat{a}_{k,f}$ and $\hat{a}_{k,b}$ from forward DFE and reverse DFE respectively, at the first stage.

In the second stage, the estimated data $\hat{a}_{k,f}$ and $\hat{a}_{k,b}$ are reconstructed pass through the channel to form noise-free signal. This tries to estimate of the received data r_k : reconstructed data can be expressed as

$$\hat{r}_{k,f} = \sum_{i=-L_2}^{L_1} h_i \hat{a}_{k-i,f} \qquad (4)$$

$$\hat{r}_{k,b} = \sum_{i=-L_2}^{L_1} h_i \hat{a}_{k-i,b} \qquad (5)$$

The final stage in BAD is the arbitration stage. The purpose of arbitration state is to arbitrate the symbol decision between $\hat{a}_{k,f}$ and $\hat{a}_{k,b}$ based on the minimum error in windowed size $W_1 + W_2 + 1$. The computation parameter is given by

$$\lambda_{k,f} = \sum_{j=-W1}^{W2} r_{k+j} - \hat{r}_{k+j,f}^{\,2} \qquad (6)$$

$$\lambda_{k,b} = \sum_{j=-W1}^{W2} r_{k+j} - \hat{r}_{k+j,b}^{\,2} \qquad (7)$$

The decision $\hat{a}_k$ can be formulated under criteria as

$$\hat{a}_k = \begin{cases} \hat{a}_{k,f}, & \lambda_{k,f} \le \lambda_{k,b} \\ \hat{a}_{k,b}, & \lambda_{k,f} > \lambda_{k,b} \end{cases} \qquad (8)$$

B. *Extend Bi-direction Arbitrated DFE (E-BAD) Algorithm*

In this section, the E-BAD algorithm is described. In the second state of BAD algorithm, data is re-constructed and an accumulation error is computed for forward and reverse equalizer. In the Extend BAD, we re-construct and calculate error again from difference source. The additional source is Soft Decision Feedback symbol and the BAD symbol is another input to the second state. Following the same method, the low correlation error is used again for make the best match with original received data. The soft-decision feedback equalizer is illustrated in Fig. 2. A soft decision feedback calculation can be expressed as follows [5]:

$$z_k = \tanh(\frac{y_k}{\alpha}) \tag{9}$$

$$\alpha = 10^{\frac{SNR}{10}} \left| HH^T \right\| FF^T \left| \right. \tag{10}$$

where T is the transpose operator.

The Extend BAD is depicted in Fig. 3. Using Eqs. (4), (5), (6), (7) and (8) to find the possibly correct data as the first times second BAD state.

III. Simulation Results Analysis

We first illustrate the performance of DFE structure among conventional DFE, SD-DFE, and Ideal DFE to show the degradation due to error propagation in DFE structure. We then show the performance of an Extend BAD algorithm that used SD-DFE structure in an extension block and compared to conventional BAD in Fig. 4. The simulation model is based on an uncoded MEEPR4 magnetic recording channel with binary input that are $H(D) = 5 + 4D - 3D^2 - 4D^3 - 2D^4$. The equalizer tap coefficients are chosen to be 31 and 9 for feed forward and feedback equalization, respectively. Windowed Distance size W is selected to 15 for simplicity. Each BER point was calculated using several 4,096 data blocks as need to collected 1,000 error bits.

A conventional BAD lag behind E-BAD whose 12 dB perform BER at 1.25e-5 and 0.79e-5, respectively. The Ideal BAD structure performance is better than E-BAD and BAD that of 0.6 dB and 0.8 dB at BER 2e-5.

Less error propagation of Ideal DFE structure in the Ideal BAD perform better performance than the other BAD algorithm. Even we reduce burst error of BAD structure by adding an Extend SD-DFE. The key to improve performance of BAD algorithm is to reduce error propagation in the structure as shown in the Ideal BAD.

IV. Conclusions

In this paper, an Extend Bi-directional Arbitrated Decision Feedback Equalizer had been presented. The traditional BAD algorithm is improved by adding another equalization symbol from an extend SD-DFE. Among equalization symbol posses the low correlation errors whose the benefit is used in arbitration state. E-BAD performance is better than conventional BAD over MEEPR4 channel with data uncoded system. The performance is improved due to burst error is

mitigated using among three equalization data. In fact, the BAD performance can by further improved by reducing error propagation in BAD structure. E-BAD is the modification level of BAD algorithm and perform better performance which can be used to several environment provided that the channel are known to the receiver.

***Abstract*— The narrowband interference can affect the performance of the UWB time hopping (TH) system. Therefore, interference suppression technique is important for UWB communication to operate over spectrum with established narrowband system. In this paper, the interference suppression technique based on modified template waveform for correlation receiver is employed, where the modulation techniques and path loss model are considered. Our study demonstrates that the BER performance of the modified template waveform is better than the original one. Therefore, the modified template waveform based correlation receiver is simple and low complexity technique which can improve the system performance significantly.**

I. INTRODUCTION

Ultra wideband (UWB) radio technology has a great interest in wireless networking. UWB offers many advantages which can be described as the potential for low cost, low power transmission, high data rates and immunity to multipath. Instead of using a narrow carrier frequency, UWB transmits pulses of power spectral density (PSD) in the range of the ultra wide frequency spectrum. The Federal Communications Commission (FCC) defines UWB as any signal that occupies more than 500 MHz in the frequency range of 3.1-10.6 GHz with the maximum emission power of -41.3 dBm/MHz [1]. Because of the transmission at low power, the UWB signal is considered to be noise for other communication systems. Therefore, UWB radio technology can coexist with other RF technologies without interference. Unfortunately, at close proximity, UWB radio can induce interference and degrade the throughput of the other system.

Numerous literatures study on UWB interference to other existence narrowband system [2]-[8]. On the other hand, there are few research study on the influence of narrowband interference (NBI) to UWB communication system. Especially, the IEEE 802.11a wireless LAN system operates at 5 GHz bands which overlaps the UWB spectrum [9]. This system uses orthogonal frequency division multiplexing (OFDM) based transmission. In [10], the coexistence of UWB system and wireless LANs is investigated for LOS and NLOS propagation scenarios. The results show that wireless LAN interference can greatly impact the performance of the UWB receiver. Similarly, the interference from a nearby NBI will affect UWB performance also provides in [11]. While the analytical approach of the IEEE 802.11a interference on UWB systems is given in [12]. Therefore, the interference suppression technique is required for UWB communication.
